Dosage and administration An initial dose of 150 mg/kg body weight of N-acetylcysteine is infused in 200 ml of 5% dextrose intravenously over 15 minutes, followed by an intravenous infusion of 50 mg/kg body weight in 500 ml of 5% dextrose over the next four hours, and 100 mg/kg body weight in 1 litre of 5% dextrose over the next 16 hours. (This gives a total dose of 300 mg/kg body weight of N-acetylcysteine in 20 hours.)

Children: The quantity of intravenous fluid used in children should be modified to take into account age and weight.

Critical times: Parvolex is very effective when administered up to eight hours after paracetamol overdosage. The protective effect falls off slowly between 8 and 10 hours, more rapidly after 10 hours and increasingly between 12 and 15 hours. Parvolex is ineffective after 15 hours and its use after this time may be associated with harmful effects.

Contra-indications, warnings, etc No contra-indications have been reported.

Precautions: N-acetylcysteine is not compatible with rubber and metals, particularly, iron, copper and nickel. Silicone rubber and plastic are satisfactory for use with Parvolex.

Side-effects: Rash and anaphylaxis have been reported.

Hypokalaemia and ECG changes have been noted in patients with paracetamol poisoning irrespective of the treatment given. Monitoring of plasma potassium concentration is therefore recommended. The safety of Parvolex in pregnancy has not been established.

Overdosage: There is a theoretical risk of hepatic encephalopathy. There is no specific treatment and general supportive measures should be carried out.

Pharmaceutical precautions Parvolex should be stored in a cool place.

Legal category POM.

Package quantities Parvolex is supplied in ampoules of 10 ml. 10 × 10 ml ampoules are packed in printed cartons.

Further information Nil.

Product licence number 0021/0086.

PERNIVIT* TABLETS

Presentation Salmon-pink, sugar-coated tablets, each tablet containing:

Acetomenaphthone BP	7 mg
Nicotinic Acid BP	25 mg

Uses The action of Pernivit is based principally on the vasodilating effect of nicotinic acid while aceto-

menaphthone (vitamin K analogue) is to alleviate symptoms. A combination of these substances, Pernivit has long been recognised as a useful preparation for the prophylaxis of chilblains.

Dosage and administration *Adults:* 2-times a day after meals.

Children: 1-2 tablets three times a day a prophylactic treatment half the recom should be taken.

Patients with advanced atherosclerosis the maximum benefit from Pernivit.

Contra-indications, warnings, etc

Contra-indications: Patients who are on a coagulant therapy.

Precautions: Pernivit should be given to patients with a history of peptic ulceration receiving antihypertensive agents.

Allergic reactions to Pernivit have been rare occasions and treatment should be sought if they appear.

Notice should be taken of current view: should be prescribed with caution during

Side-effects: A flushing of the face associated with the tablets, but this is not

Overdosage: The toxic effects normally seen with treatment.

Pharmaceutical precautions There are no special requirements or precautions.

Legal category P.

Package quantities Pernivit Tablets are supplied in containers of 100.

Further information Nil.

Product licence number 0021/5083.

PROSPAROL* EMULSION

Presentation A white emulsion containing Arachis Oil BP in water and providing 4.5 (1.9 MJ per 100 ml).

Uses The special homogenising process used in the manufacture of Prosparol produces extremely small particles of approximately 1-2 microns in diameter which have little tendency to separate out. The emulsion is palatable and better tolerated than other oil emulsions.

In radiology (cholecystography): Prosparol is an essential part of a satisfactory gall-bladder examination - quick absorption, reliable visual examination.

In dietetics: Prosparol is indicated in traumatic and ketogenic diet in the management of convalescence, whenever a high calorie diet is required to minimise tissue destruction and favour repair. It is also indicated following trauma, or in preparation for surgery should provide an adequate margin of safety. It is a requirement to correct possible deficits: for total nourishment and 2,000 calories would permit steady weight gain.

Dosage and administration *Cholecystography:* 60 ml.

Dietetics: Up to 500 ml (2,250 calories

generally be administered without any digestive disturbance. It is best given in frequent small doses 20–40 ml at a time.

Prosparol may be taken neat, or diluted with milk or fruit juice; some patients prefer it chilled. It can be given orally or by nasogastric tube. 1 oz (28.3 g) Prosparol mixed with 1 oz sugar in $\frac{1}{2}$ pint (284 ml) water can be used as a non-protein milk substitute in tea, coffee or made into custard or instant whip.

Easily prepared supplemental and total diets containing Prosparol have been recommended in conjunction with milk, lactose and finely divided protein e.g. Casilan* (Farley), with the addition of electrolytes as needed.

Infants with sugar intolerance can be fed initially with a low-fat preparation and then, when they begin to thrive, to increase the fat intake gradually by adding Prosparol to the feeds. Prosparol is a valuable calorific supplement to Aminogran* (Allen & Hanburys), and other amino-acid preparations used in the management of phenylketonuria.

For the dietetic treatment of patients with anorexia nervosa, a liquid diet has been suggested containing Prosparol, Complian* (Farley) and glucose suitably flavoured with instant coffee or cocoa.

Contra-indications, warnings, etc There are no contra-indications.

Precautions: Prosparol should only be given to diabetic patients as part of their diet.

Patients with liver or gall-bladder disorders are unlikely to tolerate appreciable quantities of Prosparol.

Side-effects: Occasional fat intolerance may be encountered.

Overdosage: An overdosage will produce intolerance and no special treatment is necessary.

Pharmaceutical precautions Prosparol should be stored in a cool place but must not be frozen.

Legal category P.

Package quantities Prosparol is available in containers of 1 litre.

Further information Fat contains considerably less bulk per calorie than does protein or carbohydrate and here is over 90% absorption.

Unlike protein, fat is not wasted by 'spill-over' through the kidneys and the small rise in blood sugar following at ingestion causes less interference to appetite than do carbohydrates.

Prosparol contains 0.1% w/v Sodium Benzoate (6.9 milliequivalents of sodium per litre); it does not contain potassium.

Product licence number 0021/5009.

SCOLINE*

Presentation A clear colourless, sterile solution containing Suxamethonium Chloride (succinylcholine chloride) BP 50 mg per ml. This is equivalent to 36.5 mg of active cation.

Uses Scoline is a depolarising, short-acting neuromuscular blocking agent for intravenous administration. It is suitable for brief procedures in which profound muscular relaxation is required such as tracheal intubation, short operations, orthopaedic manipulations, electroconvul-

sive therapy and closure of the peritoneum. Prolonged muscular relaxation in surgery can be attained by means of repeated injections of the drug or by continuous intravenous drip.

Dosage and administration Scoline must not be administered to the conscious patient. It is given intravenously after anaesthesia has been induced and should be accompanied by assisted respiration. The dosage for children and adults depends on body weight and the degree of muscular relaxation required. It ranges from 20 mg (0.4 ml) to 100 mg (2 ml) according to the body weight of the patient and the degree of muscular relaxation required. In adults the dosage for intubation is from 50 mg (1 ml) to 80 mg (1.6 ml), for electroconvulsive therapy 40 mg (0.8 ml) to 75 mg (1.5 ml) and for manipulation 80 mg (1.6 ml). For administration by continuous intravenous drip, a 0.1% solution may be prepared by mixing 10 ml injection of Scoline with 500 ml of 5% glucose or isotonic sodium chloride. The adult dose ranges from 2–5 mg per minute.

Contra-indications, warnings, etc

Contra-indications: Scoline should not be used in patients known to have atypical serum pseudocholinesterase or low serum levels of pseudocholinesterase. Deficiency of this serum enzyme may occur as a very rare inherited characteristic or result from liver disease, severe anaemia, malnutrition or poisoning with an organo-phosphorus insecticide.

Patients with myasthenia gravis are resistant to Scoline and a state of dual block may develop rapidly.

Patients with the myasthenic (Eaton-Lambert) syndrome are relatively sensitive to Scoline and the dose should be reduced.

If eye drops containing long-acting cholinesterase inhibitor drugs, such as ecothiopate iodide (Phospholine iodide* Ayerst Laboratories Ltd) or demecarium bromide (Tosmilen* Astra Chemicals), are used within a period of one month prior to an operation, then decreased plasma cholinesterase levels may preclude the use of Scoline.

Scoline should not be used in ophthalmic cases when the anterior chamber of the eye is open. Nor must it be used in cases of hyperkalaemia.

Precautions: Neostigmine and other anticholinesterase drugs are not antidotes to Scoline but would normally have the effect of intensifying the depolarisation effect. However, in some cases of prolonged apnoea following Scoline, a state of 'dual block' may be responsible. In dual block the muscle relaxation is due to non-depolarising blockade and is reversible with neostigmine. To investigate this possibility the short-acting anticholinesterase drug, edrophonium, should be given and a transitory return of muscle power confirms the presence of dual block, which can then be reversed with neostigmine. In seriously burnt children Scoline can precipitate gross cardiac arrhythmias and cardiac arrest. This can be prevented by the administration of tubocurarine 6 mg five minutes before giving Scoline. Care should be taken with patients currently receiving systemic antibiotics such as streptomycin, neomycin, kanamycin, tobramycin, framycetin, amikacin, gentamicin, colistin and the polymyxins, as they can potentiate the action of Scoline.

Side-effects: Muscle pain (particularly in the muscles of the chest, abdomen and shoulder girdle) can occur following the use of Scoline. It occurs most frequently in patients who are ambulant in the early postoperative period and can be avoided by the prior administration of any of the non-depolarising muscle relaxants.

Other side-effects which have been reported include hypertension, fever and hypersensitivity reactions.

Overdosage: Because Scoline is usually administered by an anaesthetist, overdosage is unlikely. However, the unsuspected presence of low pseudocholinesterase levels in the serum, or this being replaced by the atypical enzyme, or the occurrence of dual block, can lead to a similar situation: prolonged apnoea. Management first consists of maintaining light anaesthesia and continued mechanical respiration to ensure an adequate supply of oxygen whilst the cause is determined. Dual block can be recognised by the response to edrophonium, and treatment then consists of reversal with neostigmine. Subsequently the patient should remain under observation as the dual block may outlast the duration of action of neostigmine (at least 20 minutes) and if apnoea recurs a further dose of neostigmine is indicated. Apnoea due to atypical or low serum cholinesterase levels can be corrected by intravenous administration of a highly concentrated preparation of pseudocholinesterase or transfusion of plasma or whole blood.

Pharmaceutical precautions Scoline should be stored at as low a temperature as possible above its freezing point and not exceeding 4°C; under these conditions it may be expected to retain its potency for at least two years from the date of preparation.

Legal category POM.

Package quantities Scoline is available in boxes of five 2 ml ampoules and in 10 ml multidose vials.

Further information Nil.

Product licence number 0021/5024.

ADSORBED TETANUS VACCINE BP (PTAH) (Tet/Vac/Ads)

Presentation Adsorbed Tetanus Vaccine BP (PTAH) is the detoxified toxin of *Clostridium tetani* adsorbed on aluminium hydroxide: each 0.5 ml dose contains not less than 40 i.u. of tetanus toxoid.

Uses Active immunisation against tetanus. Reinforcement of immunity to tetanus.

Vaccine should be administered by intramuscular injection.

Primary immunisation: The course consists of 3 doses each of 0.5 ml; the second dose is administered after an interval of 6–8 weeks and the third dose after a further interval of four to six months.

Reinforcing doses: A reinforcing dose of 0.5 ml should be given 5 years after basic course; subsequently at 5–15 year intervals. At the time of an injury likely to carry risk of tetanus (although it is not usually necessary for any subject who is known to have received a booster dose in the preceding year).

A full course is unnecessary for such subjects who have completed the basic three dose course of toxoid. A booster or recall dose given at any time afterwards can be expected to provide reinforcement of immunity.

Contra-indications, warnings, etc

Contra-indications: Acute infection is a contra-indication to routine tetanus immunisation, except in the presence of a tetanus-prone wound.

Warnings: A sterile syringe and Adrenaline Injection BP

should be ready for use, in case the need arises for emergency treatment of an allergic reaction.

Not for intradermal use.

Side-effects: Transient pyrexia, headache, malaise, local swelling, redness and tenderness may occur especially in adults.

A small painless nodule may form at the injection site.

Acute allergic reactions, pallor, dyspnoea, urticaria, angioneurotic oedema and acute anaphylactic reactions, are sometimes seen.

Pharmaceutical precautions Protect from light. Store between 2°C and 8°C (36°F and 46°F). Do not freeze. Partly used multi-dose containers should be discarded within 3 hours of the withdrawal of the first dose.

Legal category POM.

Package quantities Single-dose ampoules containing 0.5 ml and multidose vials containing 5 ml.

Further information Adsorbed tetanus vaccine may be administered at the same time as, but at a different site from Human Tetanus Immunoglobulin or Tetanus Antitoxin.

Product licence number 0021/0060.

TIGLYSSIN* TABLETS

Presentation A white tablet engraved DF/T, each tablet containing tigloidine hydrobromide 250 mg.

Uses Tigloidine, the tiglic acid ester of pseudotropine, possesses certain properties of atropine but lacks anticholinergic activity. Tiglyssin can assist the relief of muscular spasticity and spasms due to organic upper motor neurone disease or damage occurring as a result of partial or complete rupture of the cord; multiple sclerosis; transverse myelitis; cerebrovascular accidents; subacute combined degeneration of the cord.

Dosage and administration **Adults:** The optimum therapeutic dose lies between 4 and 8 tablets per day. Tiglyssin is not recommended for children.

The appropriate level for each patient should be found by starting at 3–4 tablets and increasing the dose until either no further improvement is noted, or mild atropine-like side-effects appear. The dose should be divided and given three times daily with meals. Administration for up to four weeks is usually required for the full therapeutic effect to become apparent; the value of the drug may then be assessed.

Contra-indications, warnings, etc There are no contra-indications.

Precautions: Tiglyssin should be given with care to patients with glaucoma.

Notice should be taken of current views that any drug should be prescribed with caution during pregnancy.

Side-effects: Slight atropine-like effects are sometimes seen, particularly at the higher dosage levels.

Overdosage: Standard procedures, similar to those for atropine, should be employed: gastric aspiration and lavage with dilute tannic acid solution, followed by a saline purge.

Pharmaceutical precautions No special requirements or precautions.

Legal category POM.

Package quantities Tiglyssin Tablets are available in tainers of 100.

ther information The effect of Tiglyssin is purely ative. It can have no curative effect nor can it delay advance of progressive diseases such as multiple rosis. Nevertheless, apart from increasing comfort

and making nursing easier, relief of spasticity and spasms may, in some patients, help in rehabilitation and in others reveal a useful amount of normal function yet remaining.

Product licence number 0021/5076.

COLOFAC®

Presentation White sugar-coated tablets each containing 135 mg mebeverine hydrochloride.

Uses Mebeverine is a musculotropic antispasmodic with a direct action on the smooth muscle of the gastro-intestinal tract, relieving spasm without affecting normal gut motility. Since this action is not mediated by the autonomic nervous system, the usual anticholinergic side-effects are absent. Mebeverine is suitable for patients with prostatic hypertrophy and glaucoma.

Indications:

1. Irritable bowel syndrome and other conditions usually included in this grouping such as: chronic irritable colon, spastic constipation, mucous colitis, spastic colitis. Colofac is effectively used to treat the symptoms of these conditions, such as: abdominal pain and cramps, persistent, non-specific diarrhoea (with or without alternating constipation) and flatulence.

2. Gastro-intestinal spasm secondary to organic diseases such as diverticular disease, gastritis, duodenitis, oesophagitis, cholecystitis, Crohn's disease, ulcerative colitis, peptic ulcer, gall bladder disease, hiatus hernia and specific and non-specific inflammatory disease of the gastro-intestinal tract.

Dosage and administration *Adults:* One tablet three times a day, preferably 20 minutes before meals.

After a period of several weeks when the desired effect has been obtained the dosage may be gradually reduced.

Children under 10: Not applicable.

Contra-indications, warnings, etc

Contra-indications: None known.

Warnings: Animal experiments have failed to show any teratogenic effects. However, the usual precautions concerning the administration of any drug during pregnancy should be observed.

Treatment of overdosage: On theoretical grounds it may be predicted that CNS excitability will occur in cases of overdosage. No specific antidote is known; gastric lavage and symptomatic treatment is recommended.

Pharmaceutical precautions Store in a dry place, at room temperature, protected from light.

Legal category POM.

Package quantities Available in packs of 100 (5 strips of 20 blister-packed tablets).

Further information Results from a preliminary study show that mebeverine does not produce false positive reactions in standard diagnostic urine tests.

Product licence number 0512/0044.

DUPHALAC®

Presentation A colourless to pale yellow syrup containing lactulose 3.35 g/5 ml. Also contains lactose 0.3 g/5 ml, galactose 0.55 g/5 ml.

Uses The action of Duphalac in treating constipation depends on the inability of the enzymes in the small intestine to hydrolyse the synthetic disaccharide, lactulose, into its component molecules of fructose and galactose. Therefore, as lactulose is virtually unabsorbed, it passes into the large bowel chemically unchanged and forms a substrate for commensal saccharolytic bacteria.

The resulting breakdown products, simple organic compounds like lactic and acetic acid, give rise to increased intra-colonic osmotic pressure, with consequent increased faecal bulk, and stimulate peristalsis. The growth of saccharolytic bacteria is favoured and the normal colonic flora restored.

A soft stool is formed, and normal bowel action encouraged without irritation or direct interference with the gut mucosa.

In patients with hepatic encephalopathy larger doses of Duphalac are used; a significant reduction in the pH of the colonic contents results, which reduces markedly the formation and absorption of ammonium ions and other nitrogenous toxins into the portal circulation. Rapid decrements in blood ammonia concentration have been reported following Duphalac treatment.

Indications: 1. Constipation.

2. Hepatic encephalopathy (Portal systemic encephalopathy); hepatic coma.

Dosage and administration *Constipation:* Initially Duphalac may be given twice daily. In due course the dose should be adjusted to the needs of the individual but the following serves as a guide.

Starting dose

Adults	15 ml twice daily
Children 5 to 10 years	10 ml twice daily
Children under 5 years	5 ml twice daily
Babies	2.5 ml twice daily

Each dose of Duphalac may, if necessary, be taken with water or fruit juices, etc.

Hepatic encephalopathy: Initially 30–50 ml. (6–10 × 5 ml spoonfuls) three times a day. Subsequently adjust the dose to produce two or three soft stools each day.

Contra-indications, warnings, etc

Contra-indications: Galactosaemia. In common with other preparations used for the treatment of constipation Duphalac should not be used when there is evidence of gastro-intestinal obstruction.

Precaution: Lactose intolerance.

Pharmaceutical precautions Store below 20°C. Do not freeze. Dilution and subsequent storage not recommended.

Legal category P.

Package quantities Available in bottles of 300 ml and 1 litre.

Further information Because of Duphalac's physiological mode of action it may take up to 48 hours before effects are obtained. However, clinical experience has shown that this medicament does exhibit a 'carry-over' effect which may enable the patient to reduce the effective dose gradually over a period of time.

A maintenance dose of 15 ml per day provides only 58 kJ (14 kcals), and is therefore, unlikely to adversely affect diabetics.

Product licence number 0512/5001.

DUPHASTON®

Presentation White, flat, round tablet imprinted DUPHA- on one side, scored on reverse, each containing 10 mg Dydrogesterone BP.

Uses Dydrogesterone is an orally active progestogen which produces a complete secretory endometrium in an oestrogen-primed uterus. It is indicated in all cases of endogenous progesterone deficiency.

Indications: Dysmenorrhoea, endometriosis, threatened and habitual abortion (associated with proven progesterone deficiency), infertility, irregular cycles, functional bleeding (with added oestrogen), secondary amenorrhoea (with added oestrogen), premenstrual syndrome, conditions of progesterone deficiency and to counteract the effects of unopposed oestrogen in Hormone Replacement Therapy.

Dosage and administration *Dysmenorrhoea:* 10 mg twice daily from day 5 to 25 of the cycle.

Endometriosis: 10 mg two to three times daily from day 5 to 25 of the cycle, or continuously.

Threatened abortion: 40 mg at once then 10 mg every eight hours until symptoms remit. If symptoms persist or return during treatment the dose can be increased by one tablet every eight hours. The effective dose must be maintained for a week after symptoms have ceased and then be gradually decreased unless symptoms return.

Habitual abortion: Treatment should be started as early as possible, preferably before conception. 10 mg should be given twice daily from day 11 to day 25 of the cycle until conception and then continuously (10 mg twice daily) until the twentieth week of pregnancy, then dosage may be gradually reduced.

Infertility or irregular cycles: 10 mg twice daily from day 1 to day 25 of the cycle. Treatment should be maintained for at least six consecutive cycles. If the patient conceives, it is advisable to continue treatment or the first few months of pregnancy as described under 'habitual abortion'.

Unfractional bleeding – to arrest bleeding: 10 mg twice daily together with an oestrogen once daily for five to seven days.

Unfractional bleeding – to prevent bleeding: 10 mg twice daily together with an oestrogen once daily from day 11 to 25 of the cycle.

Amenorrhoea: An oestrogen once daily from day 1 to 25 of the cycle, together with 10 mg dydrogesterone twice daily from day 11 to 25 of the cycle.

Pre-menstrual syndrome: 10 mg twice daily from day 12 to 26 of the cycle. The dosage may be increased if necessary.

Contra-indications, warnings, etc

Contra-indications: None known.

Warning: Breakthrough bleeding may occur in a few patients. It can, however, be prevented by increasing the dosage.

Treatment of overdosage: No reports of ill effects from overdosage have been recorded and remedial action is generally unnecessary. If a large overdosage is discovered within 2–3 hours and treatment seems desirable, gastric lavage is recommended. There are no special antidotes and treatment should be symptomatic.

Pharmaceutical precautions Store in a dry place, at room temperature, protected from light.

Legal category POM.

Package quantities Available in packs of 40 (4 strips of 10 blister-packed tablets).

Further information Duphaston is non-androgenic, non-oestrogenic, non-thermogenic, non-corticoid, non-anabolic and is not excreted as pregnanediol.

Results from a preliminary study show that dydrogesterone does not produce false positive reactions in standard diagnostic urine tests.

Product licence number 0512/5004.

DUVADILAN®

Presentation 1. Round, pink tablets imprinted with the name 'Duvadilan' on one face, scored on the reverse, each tablet containing 20 mg isoxsuprine hydrochloride.

2. Ampoules containing a clear, colourless solution of isoxsuprine hydrochloride 5 mg/ml.

Uses Duvadilan (isoxsuprine hydrochloride) is a vaso-relaxant which acts through stimulation of the beta-receptors situated in the walls of blood vessels, especially cerebral vessels and the deeper vessels of the limbs. In high doses it also relaxes skin vessel walls, where alpha-sympathetic receptors predominate. Isoxsuprine also lowers blood viscosity. In addition, isoxsuprine has a stimulating action on the beta-adreno-receptors of the myometrium with a resulting inhibition of uterine contractions. In high doses, it also has a direct papaverine-like action on the smooth muscle of the uterus.

Indications: Peripheral vascular disorders: arteriosclerosis, Buerger's disease, Raynaud's syndrome, ischaemic and vasospastic symptoms (e.g. intermittent claudication, night cramps, pain in limbs, paraesthesia, cold extremities, ulcers).

Cerebral vascular disorders: cerebral insufficiency, occlusive and thromboembolic disorders, transient ischaemic episodes (e.g. dizziness, headache, insomnia, confusion, forgetfulness).

Premature labour.

Dosage and administration *Cerebral and peripheral vascular disease:* 1. Intravenous infusion: 100 mg isoxsuprine hydrochloride in 500 ml normal saline or 20 mg isoxsuprine hydrochloride in 100 ml normal saline in a burette apparatus.

Recommended infusion rates: For maximum infusion time of one hour twice daily, start at:

0.5 ml/min (0.1 mg/min) for 10 minutes.

1.0 ml/min (0.2 mg/min) for next 10 minutes.

1.5 ml/min (0.3 mg/min) for next 10 minutes.

2.0 ml/min (0.4 mg/min) for the remaining 30 minutes.

Note: If after 10 minutes at 2.0 ml/min there are no side-effects observed an infusion rate of 2.5 ml/min (0.5 mg/min) may be adopted for the remaining 20 minutes.

2. Intramuscular/intra-arterial injection: Duvadilan Injection (10 mg in 2 ml) may be given by intramuscular or intra-arterial routes up to four times daily.

3. Oral: Tablets, 20 mg isoxsuprine hydrochloride, four times daily. Capsules, equivalent of 40 mg isoxsuprine hydrochloride in a sustained release formulation, morning and evening (see Duvadilan Retard).

Premature labour:

1. Intravenous infusion: To be administered at the onset of premature labour and continued until control is obtained.

Infusion solution: Duvadilan 100 mg in 500 ml normal saline.

Infusion rate: 1.0–1.5 ml/min (0.2–0.3 mg/min) increasing up to 2.5 ml/min (0.5 mg/min) until control is obtained.

Blood pressure and heart rate should be checked regularly during intravenous infusion. Adjustment of the drip rate should be made according to the result and possible side-effects such as a serious drop in blood pressure.

2. Intra-muscular injection: When labour is arrested: Duvadilan 10 mg (1 × 2 ml ampoule) three hourly for 24 hours, then four to six-hourly for a further 48 hours.

3. Oral: When contractions have ceased for 48 hours Duvadilan 1 × 20 mg tablet four times a day.

Contra-indications, warnings, etc

Contra-indications: Recent arterial haemorrhage, par- enteral use in patients with known heart disease, premature detachment of placenta, and severe anaemia.

Precaution: Patients in premature labour should be maintained in the lateral position during infusion. Blood pressure and heart rate should be recorded regularly during infusion. If a prolonged fall in blood pressure occurs the rate of infusion should be reduced or the infusion discontinued.

Side-effects: Hypotension (see Precautions); transient tachycardia, mild flushing, nausea and vomiting have been noted. If it is necessary to reverse the cardiovascular effects, treatment with a non-selective beta-blocker should be considered.

Treatment of overdosage: Gross overdosages have not been reported, treatment would be gastric lavage, and if necessary, a non-selective beta-blocker may be administered intramuscularly.

Pharmaceutical precautions Injections should be stored above 0°C but below 20°C, protected from light. The infusion may be prepared with dextrose or isotonic saline.

Duvadilan Tablets 0512/5002

Duvadilan Injection 0512/5003

DUVADILAN* RETARD

Presentation Isoxsuprine in a graded release formulation. Red/opaque white, hard gelatine capsules, im printed 'DUV.RET. duphar'. Each capsule contain isoxsuprine (equivalent to 40 mg of the hydrochloride complexed with a sulphonated polystyrene resin).

Uses The active ingredient is isoxsuprine, which has direct vasorelaxant effect on the vascular wall and has also viscosity lowering properties. Its vasodilating action is more marked on the intracerebral vessels, arteries and arterioles where the beta-sympathetic receptors predominate.

Indications: Cerebral and peripheral arteriosclerosis; cerebral and peripheral vasospasm; acute vascular occlusion; Buerger's disease; acrocyanosis; thrombophlebitis; Raynaud's disease.

Dosage and administration *Adults:* 1 capsule morning and evening.

The product is not intended for administration to children.

Contra-indications, warnings, etc

Contra-indication: Recent arterial haemorrhage.

Side-effects: Side-effects in the form of flushing and palpitations are rare and transient.

Treatment of overdosage: Gross overdosages have not been reported; treatment would be gastric lavage, and necessary, a non-selective beta-blocker may be administered intramuscularly.

Pharmaceutical precautions Store in a dry place at a temperature below 20°C.

Legal category P.

Package quantities Compliance pack of 56 capsules (4 strips of 14 blister packed capsules).

Further information Duvadilan Retard can be given to patients with hypertension, diabetes, coronary insufficiency, peptic ulcer and glaucoma. Duvadilan Retard may also be given with the commonly used diuretics, corticosteroids and antihypertensive drugs.

Results from a preliminary study show that isoxsuprine does not produce false positive reactions in standard diagnostic urine tests.

Product licence number 0512/0030.

INFLUVAC*

Presentation Disposable syringes and ampoules containing 0.5 ml, vials containing 5 ml and 25 ml of colourless, opalescent suspension of inactivated influenza virus strains. The product contains appropriate quantities of the A and B strains currently recommended by WHO.

Uses Prophylaxis of influenza. Particularly recommended in:

1. Chronic pulmonary disease, e.g. chronic bronchitis and emphysema, asthma, bronchiectasis, pulmonary tuberculosis and fibrosis.
2. Chronic heart disease, e.g. valvular and hypertensive heart disease.
3. Chronic renal disease, e.g. chronic nephritis, including patients with renal disease on immunosuppressive drugs.
4. Diabetes and possibly other less common endocrine disorders.
5. Elderly people.
6. Key workers in essential services, such as personnel in hospitals, public services and in industry, where temporary absence may constitute a serious problem.

Dosage and administration

Adults and children (over 13 years): 0.5 ml.

Children (9–13 years): 0.5 ml, followed by a second injection of 0.5 ml not less than 4 weeks later, unless previously primed with H₁N₁ antigen, in which case one dose of 0.5 ml is sufficient.

Children (under 9 years): Not recommended.

to be given by intramuscular injection after allowing the vaccine to reach room temperature. It is recommended that the contents of multi-dose vials are used within 8 hours of opening. The vaccine may be expected to protect the recipient 10–21 days after injection for a period of approximately 12 months.

Contra-indications, warnings, etc

Contra-indications: Persons with hypersensitivity to eggs, chicken proteins or feathers should not be vaccinated.

Immunisation should be postponed in patients with febrile illness.

Warnings: Although the incidence of side-effects with influenza, purified by zonal centrifugation, is minimal, a transient erythema, painful arm or tenderness at the site of injection or mild fever may appear within the first forty-eight hours.

Neurological disorders such as encephalomyelitis and neuritis after influenza vaccination have rarely been reported. An association has not been demonstrated except in the case of the Guillain Barré Syndrome (USA mass vaccination programme 1976).

The vaccine contains a maximum per dose of 0.00625 Units polymyxin and 0.00625 mcg neomycin. Use with caution in patients hypersensitive to these antibiotics.

Pharmaceutical precautions Store at 2–10°C, protected from light. Do not freeze.

Legal category POM.

Package quantities Single-dose (0.5 ml) disposable syringes and ampoules, 10 dose (5 ml) and 50 dose (25 ml) vials.

Further information Nil.

Product licence number 0512/0053.

MONOTRIM®

Presentation Tablets – white, flat, round, with bevelled edges, imprinted with the manufacturer's symbol  on one face, with a single break bar on the other and coded $\frac{AE}{2}$. Each tablet contains 200 mg trimethoprim BP.

Tablets – white, flat, round, with bevelled edges, imprinted with the manufacturer's symbol  on one face, with a single break bar on the other and coded $\frac{AE}{2}$.

Each tablet contains 100 mg trimethoprim BP.

Suspension – white, sugar free, aniseed flavoured suspension containing 50 mg trimethoprim per 5 ml.

Uses Trimethoprim is active *in-vitro* against most Gram-positive and Gram-negative aerobic organisms. The antimicrobial activity is due to selective inhibition of bacterial dihydrofolate reductase.

Indications: Treatment of susceptible infections caused by trimethoprim-sensitive organisms including urinary and respiratory tract infections.

Dosage and administration Acute infections:

Tablets:

Adults and children over 12 years: 200 mg twice daily

Children 6 years to 12 years: 100 mg twice daily

Children 6 months to 5 years: 50 mg twice daily

Suspension:

Adults and children over 12 years: 200 mg (20 ml) twice daily

Children 6 years to 12 years: 100 mg (10 ml) twice daily

Children 6 months to 5 years: 50 mg (5 ml) twice daily

Children 6 weeks to 5 months: 25 mg (2.5 ml) twice daily

Treatment should continue for at least one week. The first dose can be doubled. The approximate dosage in children is 8 mg trimethoprim per kg body weight per day.

Long-term treatment and prophylactic therapy:

Tablets:

Adults and children over 12 years: 100 mg at night

Children 6 years to 12 years: 50 mg at night

Suspension:

Adults and children over 12 years: 100 mg (10 ml) at night

Children 6 years to 12 years: 50 mg (5 ml) at night

Children 6 months to 5 years: 25 mg (2.5 ml) at night

The approximate dosage in children is 2 mg trimethoprim per kg body weight per day.

Dosage advised where there is reduced kidney function:

Creatinine clearance (ml/sec)	Plasma creatinine (micromol/l)	Dosage advised
Over 0.45	men < 250 women < 175	normal
0.25–0.45	men 250–600 women 175–400	normal for 3 days then half dose
Under 0.25	men > 600 women > 400	half the normal dose

Contra-indications, warnings, etc

Contra-indications: Pregnancy, trimethoprim hypersensitivity, blood dyscrasias, severe renal insufficiency where blood levels cannot be monitored.

Precautions: Caution should be exercised in the administration of trimethoprim to patients with actual or potential folate deficiency and administration of folate supplement should be considered. Although an effect on folic acid metabolism is possible, interference with haematopoiesis rarely occurs at the recommended dose.

If any such change is seen, folic acid should reverse the effect. Elderly people may be more susceptible and a lower dose may be advisable. In neonates, trimethoprim should be used under careful medical supervision.

In patients with impairment of renal function, care should be taken to avoid accumulation.

Although trimethoprim is excreted in breast milk it is not a contra-indication for short-term therapy in lactating mothers.

Side-effects: Skin rashes, nausea and vomiting have been reported in rare instances.

Treatment of overdosage: Symptomatic treatment, gastric lavage and forced diuresis can be used. Depression of haematopoiesis by trimethoprim can be counteracted by intramuscular administration of calcium folinate.

Pharmaceutical precautions Monotrim Suspension may be diluted with water or sorbitol. The diluted suspension is stable for 14 days.

Legal category POM.

Package quantities

Tablets: 200 mg containers of 100 and 500 tablets
100 mg containers of 100 and 500 tablets

Suspension: Bottle of 100 ml.

Further information Trimethoprim is effective *in-vitro* against most Gram-positive and Gram-negative aerobic organisms, including *enterobacteria* – *E. coli*, *Proteus*, *Klebsiella pneumoniae*; *Streptococcus faecalis*; *Streptococcus pneumoniae*; *Haemophilus influenzae*; and *Staphylococcus aureus*.

It is not active against *Mycobacterium tuberculosis*, *Neisseria gonorrhoeae*, *Pseudomonas aeruginosa*, *Treponema pallidum*, or anaerobic bacteria.

Product licence numbers

Tablets: 200 mg 4012/0003

MONOTRIM® INJECTION

Presentation Ampoules containing a sterile, clear, colourless, aqueous solution (pH = 4.0), containing trimethoprim lactate equivalent to 20 mg trimethoprim base per ml. Each ampoule contains 5 ml corresponding to 100 mg of trimethoprim base.

Uses Trimethoprim is active *in-vitro* against most Gram-positive and Gram-negative aerobic organisms. The antimicrobial activity is due to selective inhibition of bacterial dihydrofolate reductase.

Indications: Treatment of susceptible infections caused by trimethoprim-sensitive organisms, particularly Gram-negative infections.

Dosage and administration **Dosage:** Adults and children over 12 years: 200 mg every 12 hours.

Children under 12 years: The approximate dosage in children is 8 mg trimethoprim per kg body weight per day, divided into two or three equal doses.

In severely ill patients, the initial doses may be higher or given more frequently.

Dosage advised where there is reduced kidney function:

Creatinine clearance (ml/sec)	Plasma creatinine (micromol/l)	Dosage advised
Over 0.45	men < 250 women < 175	normal
0.25–0.45	men 250–600 women 175–400	normal for 3 days then half dose
Under 0.25	men > 600 women > 400	half the normal dose

Administration: Monotrim Injection may be administered:

1. By direct intravenous injection, or intramuscular injection, or
2. Via the tubing of an established intravenous infusion.

It is compatible with the following commonly used infusion fluids:

Dextran 40 Injection BP 10% w/v in normal saline

Dextran 70 Injection BP 6% w/v in normal saline

Dextrose Injection BP 5% w/v

Laevulose Injection BP 5% w/v

Ringer's Injection USP

Sodium Chloride Injection BP 0.9% w/v

Sodium Chloride 0.45% w/v and Dextrose 2.5% w/v Injection BP

Sodium Lactate Injection BP

Compound Sodium Lactate Injection BP

Contra-indications, warnings, etc

Contra-indications: Pregnancy, trimethoprim hypersensitivity, blood dyscrasias, severe renal insufficiency where blood levels cannot be monitored.

Precautions: Caution should be exercised in the administration of trimethoprim to patients with actual or potential folate deficiency and administration of folate supplement should be considered. Although an effect on folic acid metabolism is possible, interference with haematopoiesis rarely occurs at the recommended dose. If any such change is seen, folic acid should reverse the effect. Elderly people may be more susceptible and a lower dose may be advisable.

In patients with impairment of renal function, care should be taken to avoid accumulation.

Although trimethoprim is excreted in breast milk, it is not a contra-indication for short-term therapy in lactating mothers.

Side effects: Skin rashes, nausea and vomiting have been reported in rare instances.

Treatment of overdosage: Symptomatic treatment, gastric lavage and forced diuresis can be used. Depressor of haematopoiesis by trimethoprim can be counteracted by intramuscular administration of calcium folinate.

Pharmaceutical precautions Store below 25°C protected from light.

Monotrim Injection is incompatible with solutions of sulphonamides and should not be mixed with such preparations.

Legal category POM.

Package quantities Boxes of 5 × 5 ml ampoules.

Further information Trimethoprim is effective *in-vitro* against most Gram-positive and Gram-negative

aerobic organisms, including *enterobacteria* – *E. coli*, *Proteus*, *Klebsiella pneumoniae*; *Streptococcus faecalis*; *Streptococcus pneumoniae*; *Haemophilus influenzae*; and *Staphylococcus aureus*.

It is not active against *Mycobacterium tuberculosis*, *Neisseria gonorrhoeae*, *Pseudomonas aeruginosa*, *Treponema pallidum*, or anaerobic bacteria.

Monotrim Injection may be given in conjunction with, but separately from, other parenterally administered antibacterials, for example, aminoglycosides, metronidazole or sulphonamides whenever such a combination seems suitable.

Product licence number 4012/0008.

Product licence holder: GEA Limited, DK-2000, Copenhagen F, Denmark.

SERC*

Presentation A white, flat, round tablet, imprinted 'Serc' on one face, scored on the reverse, each tablet containing 8 mg betahistine dihydrochloride.

Uses Betahistine is an orally effective treatment for Ménière's syndrome, which appears to exert its effect by reducing endolymphatic pressure. It is a histamine analogue which was developed following the successful parenteral use of histamine in patients with Ménière's syndrome. Animal studies have confirmed its specific effect. Clinical experience has demonstrated the efficacy of betahistine on all the principal symptoms of Ménière's syndrome, not only reducing vertiginous episodes and tinnitus but also arresting hearing loss.

Indications: Vertigo, tinnitus and hearing loss associated with Ménière's syndrome.

Dosage and administration **Adults:** One or two tablets three times a day, taken preferably with meals. The dosage may be adjusted according to response, up to a recommended maximum of 48 mg daily.

Children: No dosage recommendations are made for children.

Contra-indications, warnings, etc

Contra-indication: Phaeochromocytoma.

Precautions: Clinical intolerance to Serc in bronchial asthma patients has not been shown, but caution should be exercised when administering this histamine analogue to bronchial asthma patients.

High-dosage animal tests have shown no teratogenic properties, but the usual precautions should be observed when administering Serc to patients during pregnancy.

Though an antagonism between Serc and antihistamines could be expected on a theoretical basis, no such interactions have been reported.

Side-effects: There have been a small number of reports of gastric upset.

Pharmaceutical precautions As Serc Tablets are hygroscopic they should be stored and dispensed in the original unopened pack or an airtight container which should be kept in a cool dry place, away from light.

Legal category POM.

Package quantities Available in bottles of 100 tablets.

Further information Results from a preliminary study show that betahistine does not produce false positive reactions in standard diagnostic urine tests.

Product licence number 0512/5005.

TACHYROL*

Presentation A white, round, slightly biconvex tablet, imprinted 'DHT' on one face, and with a scoreline on the reverse. Each tablet contains 0.2 mg dihydrotachysterol₂ USP. XX.

Uses Dihydrotachysterol is a synthetic analogue of vitamin D. Like vitamin D and its active metabolites, dihydrotachysterol raises plasma calcium and promotes mineralisation of bone by its actions on intestinal transport of calcium and phosphate and possibly on other target tissues such as bone, kidney and the parathyroid glands. Dihydrotachysterol requires transformation by the liver (25-hydroxylation) to exert maximal biological effects but, unlike vitamin D, it does not require further metabolism by the kidney (1α -hydroxylation) for its activity.

Several disorders of mineral metabolism are known to be due in part to defective renal metabolism of vitamin D, including renal osteodystrophy, hypoparathyroidism and pseudohypoparathyroidism, and some forms of osteomalacia or rickets resistant to physiological doses of vitamin D. The use of dihydrotachysterol bypasses this metabolic block: moreover the onset and offset of action of dihydrotachysterol are more rapid than vitamin D, which facilitates titration of dose and reduces the risk of hypercalcaemia. Thus accidental hypercalcaemia can be rapidly reversed by stopping treatment.

Indications: Rickets or osteomalacia resistant to vitamin D. Post-operative hypoparathyroidism. Idiopathic hypoparathyroidism. Renal osteodystrophy.

Dosage and administration **Adults:** Initially 0.2 mg (1 tablet) daily. This dosage should be adjusted according to the requirements of individual patients as indicated by blood calcium levels (determined initially after two weeks, or earlier, then at least at monthly intervals), and appropriate clinical response.

Children: Dosage is adjusted to the requirements of individual patients as indicated by blood calcium levels.

Contra-indications, warnings, etc

Contra-indication: Hypercalcaemia.

Precautions: Overdosage is likely to cause hypercalcaemia which may be symptomless; symptoms which can occur include anorexia, nausea, vomiting, griping, polyuria and polydipsia. Chronic hypercalcaemia may lead to calcium deposition in soft tissues such as the kidney. In renal disease, hyperphosphataemia contributes to the tendency to extracellular calcium deposition, and should therefore be controlled if necessary by phosphate binding agents.

In patients with renal osteodystrophy, overdosage may increase the rate of deterioration of renal function.

Concurrent administration of barbiturates has been reported to influence vitamin D metabolism, and increased doses of dihydrotachysterol may therefore be required in patients taking barbiturates or anti-convulsant drugs.

Like all vitamin D analogues, dihydrotachysterol is excreted in breast milk. Animal experiments in rats show evidence of calcification in suckling neonatal rats, therefore it seems prudent, until human evidence is obtained to the contrary, to recommend that mothers receiving dihydrotachysterol do not nurse their infants.

Treatment of Overdosage: It is important to monitor plasma calcium, phosphate and creatinine levels, especially in patients with chronic renal failure.

There is no specific antidote to the effects of Tachyrol. As the drug is excreted rapidly from the patient, withdrawal should be sufficient in cases of overdosage.

Calcium supplements, if given, should also be stopped. Severe hypercalcaemia may be additionally treated using corticosteroids, 'loop diuretics' and i/v fluids. Hyperphosphataemia should be controlled if necessary by phosphate binding agents.

Pharmaceutical precautions Tachyrol tablets should be stored and dispensed in the original unopened pack or an airtight container. The product has a shelf-life of three years from the date of manufacture, if kept at temperatures below 20°C. Protect from light.

Legal category POM.

Package quantities Available in bottles of 75 tablets.

Further information Nil.

Product licence number 0512/0037.

YUTOPAR®

Presentation Tablets – Round, buff, with the inscription 'Yutopar' on one face; breakline on the reverse. Each tablet contains 10 mg ritodrine hydrochloride.

Injection – Clear, aqueous solution containing 10 mg/ml of ritodrine hydrochloride.

Uses Yutopar is a betamimetic drug developed for obstetric use. It mainly stimulates the beta₂-receptors, thereby decreasing uterine contractility. However, some chronotropic cardiac effect and peripheral vasodilation are also seen at therapeutic doses. Yutopar is active after oral, intramuscular and intravenous administration, and inhibits frequency and intensity of uterine contractions.

Indications:

The management of:

Uncomplicated Premature Labour.

Foetal Asphyxia in labour where it is desired to obtain uterine relaxation.

Dosage and administration *Premature labour: I/V:* To be administered as early as possible at the onset of premature labour. Initial dose 50 mcg (0.05 mg) per minute to be gradually increased according to the response by 50 mcg (0.05 mg)/minute every 10 minutes until the desired result is obtained, or the maternal heart rate reaches 140 beats per minute. The effective dosage usually lies between 150 mcg (0.15 mg) and 350 mcg (0.35 mg)/minute. The infusion should be continued for 12 to 48 hours after the uterine contractions have ceased.

I/M: If intravenous administration is considered to be inappropriate, intramuscular administration may be substituted, giving 10 mg intramuscularly every three to eight hours. The intramuscular regime should be continued for 12–48 hours following arrest of labour.

Oral: One tablet (10 mg) may be given approximately 30 minutes before the termination of intravenous therapy. The usual dosage schedule for the first 24 hours of oral maintenance is one tablet (10 mg) every two hours. Thereafter, the usual dose is one or two tablets (10–20 mg) every four to six hours depending on uterine activity and unwanted effects.

The total daily dose of oral ritodrine should not exceed 120 mg. The treatment may be continued as long as the physician considers it desirable to prolong pregnancy.

Foetal asphyxia: I/V: This treatment scheme is only recommended as a means of improving the condition of the foetus, so that intervention may be carried out under better conditions for the baby.

The recommended starting dose is 50 mcg (0.05 mg) per minute by intravenous infusion rapidly increasing the infusion rate until the uterine activity is suppressed, or the maternal heart rate reaches 140 beats per minute. The required dose is unlikely to exceed 350 mcg (0.35 mg) per minute. Whilst the infusion is given preparations should be made for the assisted delivery of the baby. Fifteen to 20 minutes after starting the infusion a foetal scalp blood sample should be taken. If the foetal scalp pH has not improved during the 15–20 minutes of infusion then the planned assisted delivery should be carried out. If the pH has significantly risen, the obstetrician may decide to continue the infusion for a further 15–30 minutes, with continued careful observation before proceeding with the delivery.

Contra-indications, warnings, etc

Contra-indications:

1. Antepartum haemorrhage which demands immediate delivery.
2. Eclampsia and severe pre-eclampsia.
3. Intra-uterine foetal death.
4. Chorioamnionitis.
5. Maternal cardiac disease.
6. Cord compression.

Precautions: Recent reports describe maternal pulmonary oedema in patients treated concomitantly with betamimetics and corticosteroids. Therefore, close monitoring under these conditions is advised.

Careful monitoring is required in patients with suspected heart disease, or those receiving other drugs, in particular those which could interact with ritodrine such as monoamine oxidase inhibitors, tricyclic antidepressants, corticosteroids, sympathomimetic amines, beta-adrenergic blocking drugs, anaesthetics used in surgery and potassium-depleting diuretics, as intravenous administration of Yutopar has been shown to decrease plasma potassium levels.

Experiments in animals have shown that even in high dosage Yutopar has no teratogenic properties. Nevertheless, in view of the limited available information from human studies, the administration of Yutopar is not recommended during the first trimester of pregnancy.

In diabetic patients, glucose levels should be closely monitored and insulin requirements adjusted accordingly during intravenous treatment. On oral treatment no alterations have been reported. It is also advisable to screen patients with potential cardiac risk before deciding on ritodrine treatment.

The drug should not be administered to patients with mild to moderate pre-eclampsia, hypertension or hyperthyroidism unless the attending physician considers that the benefits clearly outweigh the risks.

Side-effects: In appropriate dosage Yutopar is well tolerated. In particular no hypotension occurs if the recommended administration schedule is followed and the patient is maintained in the lateral position. It is only rarely that side-effects call for discontinuation of the treatment. The maternal pulse rate may progressively increase, usually to a moderate degree. This may lead to palpitations.

Any pronounced tachycardia that may arise during an intravenous infusion of Yutopar disappears shortly after decreasing the dosage or after the infusion is stopped.

Whether the maternal tachycardia is considered acceptable must be determined from case to case, but it is recommended that, in healthy patients, a heart rate of more than 140/min should be avoided.

Flushing, sweating, tremor, nausea and vomiting have been reported in a few cases. In cases of overdosage of 'utopar, a non-selective beta-sympatholytic agent may be given as an antidote.

Pharmaceutical precautions *Tablets:* Store in a cool dry place, protected from light.

Injection: Store in a cool place, protected from light. Do not use if solution is discoloured or contains a precipitate.

Compatible with commonly used infusion solutions, e.g. sterile isotonic saline or glucose/saline.

Legal category POM.

Package quantities *Tablets* – Packs of 40 tablets each containing 10 mg ritodrine hydrochloride.

Injection – Boxes of 6 × 1 ml ampoules, or 10 × 5 ml ampoules containing ritodrine hydrochloride 10 mg/ml.

Further information Less effect can be expected if the membranes are ruptured or the dilation of the cervix exceeds 4 cm.

Results from a preliminary study show that ritodrine does not produce false positive reactions in standard diagnostic urine tests.

NARCAN®
NARCAN® NEONATAL

Presentation A sterile, clear, colourless solution of naloxone hydrochloride in clear, colourless ampoules.

Narcan (1 ml ampoules): each 1 ml of solution contains 0.4 mg naloxone hydrochloride.

Narcan Neonatal (2 ml ampoules): each 1 ml of solution contains 0.02 mg naloxone hydrochloride.

Uses Narcan may be used for the complete or partial reversal of narcotic depression, including mild to severe respiratory depression induced by natural and synthetic narcotics, pentazocine, or dextropropoxyphene. It may also be used for the diagnosis of suspected acute narcotic overdosage. Narcan Neonatal may be used to counteract respiratory and other CNS depression in the new-born resulting from the administration of analgesics to the mother during childbirth.

Dosage and administration Narcan is for intravenous, intramuscular or subcutaneous injection.

1. *Narcotic Overdosage* (known or suspected). *Adults:* The usual initial adult dose of Narcan is 0.4 mg (1 ml) by i.v., i.m. or s.c. injection. If the desired degree of improvement in the respiratory function is not obtained immediately, this dose may be repeated at two to three minute intervals. Failure to obtain significant improvement after two or three doses suggests that causes other than narcotic overdosage may be responsible for the patient's condition.

Children: The usual initial dose of Narcan for children is 5–10 mcg (0.005–0.01 mg) per kg body weight. This dose may be repeated at two to three minute intervals in accordance with the adult administration guide lines.

2. *Post-operative Use:* When Narcan is used post-operatively, the dose should be titrated for each patient in order to obtain optimum respiratory response while maintaining adequate analgesia. Intravenous doses of 0.1–0.2 mg (1.5–3 mcg/kg body weight) are usually sufficient, but a full two minutes should be allowed between each 0.25 ml increment of Narcan administered. Further intramuscular doses may be needed within one to two hours, depending on the interval since the last narcotic administration and the amount and type (i.e. long or short acting) of drug used.

3. *Neonatal Use:* An adequate airway should be established in the apnoeic infant before Narcan is administered. The usual dose for narcotic induced depression is 0.01 mg/kg body weight administered i.v., i.m. or s.c. This dose may be repeated in accordance with adult administration guide lines. Alternatively, a single dose of 200 mcg (60 mcg/kg body weight) may be given intramuscularly at birth. It should however, be noted that onset of action is slower following i.m. injection.

Contra-indications, warnings, etc Narcan should not be given to patients who are known to be hypersensitive to it. It should be administered cautiously to patients who have received large doses of narcotics or to those physically dependent on narcotics since too rapid reversal of narcotic effects by Narcan may precipitate an acute withdrawal syndrome in such patients. The same caution is needed when giving Narcan to neonates delivered of such patients.

Although animal reproduction studies have not demonstrated any teratogenic or embryotoxic effects, Narcan should, like all drugs, be used with caution during pregnancy. However, Narcan may be administered to the mother during the second stage of labour to correct respiratory depression in the new-born caused by narcotics used to provide obstetrics analgesia.

Patients who have responded satisfactorily to Narcan should be kept under observation. Repeated doses of Narcan may be necessary since the duration of action of some narcotics may exceed that of Narcan.

Narcan is not effective against respiratory depression caused by non-opioid drugs.

Two patients with ventricular irritability have developed tachycardia or fibrillation following the administration of naloxone. Although a direct relationship has not been established, it is suggested that Narcan be used with caution in patients with cardiac irritability.

Overdosage: There have been no reports of acute overdosage with Narcan. Single doses of 10 mg intravenously and subcutaneous doses of 15 mg every four hours for two weeks (usual parenteral dose 0.4 mg) have been administered without producing either respiratory depression or psychotomimetic effects.

Adverse effects: Occasionally, nausea and vomiting have been reported in post-operative patients who have received Narcan in doses higher than those recommended; however, a cause and effect relationship has not been established.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Narcan ampoules each containing 1 ml are supplied in boxes of 10 ampoules.

Narcan Neonatal ampoules each containing 2 ml are supplied in boxes of 10 ampoules.

Further information Nil.

ABSELE* STERILE ABSORBABLE BONE SEALANT

Presentation A paste of putty-like consistency, sterilised by gamma irradiation and composed of:

Stabilised bovine fibrin	17.5% w/w
Solubilised bovine collagen	17.5% w/w
Dextran 70	8.0% w/w
Glycerol BP	30.0% w/w
Water	to 100

Physically it is a yellowish brown to brown, slightly sticky paste having a distinct honey-like odour. It is malleable and adheres to wet cut bone surfaces. Complete absorption of the paste has been shown experimentally in rats in two to three weeks.

Uses The paste is used to control bleeding from the divided, drilled or chipped edges of bone by physically plugging the osseous canals which contain the bleeding capillaries. It is suitable for use in neurosurgery, cardio-thoracic surgery and orthopaedic surgery.

Dosage and administration Implantation by application to bone as required to control haemorrhage.

Contra-indications, warnings, etc To date there have been no contra-indications to the use of this product.

Pharmaceutical precautions The product remains in optimum condition when stored at low temperatures. The shelf-life is two years when stored at 15°C, but storage under refrigeration will extend the expected shelf-life. Exposure to temperatures in excess of 30°C may cause irreversible adverse changes to the product.

Legal category P.

Package quantities Flat discs of approximately 2 grams in weight are packaged in a sealed inner aluminium foil pack. This pack is contained in a peel-apart secondary pack. The unit of sale is 12 packs contained in a film wrapped drawer-style carton.

Further information Absorbable bone sealant will harden if left exposed to the atmosphere for long periods, particularly under the heat of operating lights. The package should, therefore, only be opened immediately before use. The package will be damaged by caustics, chlorides and mercurials.

Product licence number 0508/0006.

BIETHIUM* STERILE ABSORBABLE OX FIBRIN PROSTHESIS

Presentation Moulded pliable implants in various shapes and sizes, sterilised by gamma irradiation and contained in a sealed foil sachet, which is in turn contained in a sterilised overwrap. The implant is composed of 65% heat treated bovine fibrin and 35%

Glycerol BP. Physically, it is a yellowish brown translucent product with a distinctive honey-like odour. It is pliable and resilient and has a specific gravity of 1.2. Absorption of the implant as observed experimentally in rats is approximately six weeks. However, if the implant is treated with a buffered formaldehyde solution prior to gamma irradiation, the absorption period can be extended for up to five months.

Uses

1. A bean-shaped prosthesis is used for the surgical correction of female stress incontinence. The bean is placed surgically at the urethro-vesical junction to reconstruct the normal angle of exit of the urethra from the bladder.

2. The buttress, buffer and button-shaped prostheses have the same basic function, namely to broaden the surface area of the suture which transfixes them in use. The buttress is rectangular and used in the repair of inguinal and incisional herniae, as well as in the resuture of the burst abdomen. The buffer is also rectangular and, used in pairs, effectively compresses the liver substance, following biopsy or liver resection, again by broadening the surface area of pressure of the ligating suture. The oval buttons are used in diaphragmatic hernia and in areas where a smaller implant is required to broaden the surface area of a suture.

Dosage and administration One bean only is required in stress incontinence, while in other procedures, several prostheses may be used, as required, according to the size of defect or damage. Administration is by implant at a surgical procedure.

Contra-indications, warnings, etc Biethium is supplied sterile and should not be resterilised.

Pharmaceutical precautions Store under normal shelf conditions. Observe expiry date.

Legal category P.

Package quantities One bean per foil pack, with five foil packs per box. Two buffers per foil pack, with five foil packs per box. Two buttons per foil pack, with five foil packs per box. Two buttresses per foil pack, with five foil packs per box. Each foil pack is overwrapped in a peel-open container. The boxes containing the foil packs are film overwrapped.

Further information *Storage:* Two years' shelf life. Avoid storing beside caustics, chlorides and mercurials which could damage the aluminium foil pack.

Product licence number 0508/0003.

POLYTEF* PASTE FOR INJECTION

Presentation A sterile, white, injectable paste in tin tubes within a see-through, peel-apart overwrap. Polytef Paste contains 50% of polytetrafluoroethylene powder

(which has been pyrolysed to purify it) in Glycerin USP containing polyoxyethylene sorbitan monolaurate (Tween 20).

Uses Polytef Paste for Injection is used for intravocal cord injection of the paralysed vocal cord. It is administered by injection directly into the cord.

Dosage and administration By injection. Dose varies according to size of cord, but should not exceed 0.6 cc per site of injection.

Contra-indications, warnings, etc Contra-indicated until at least six months have elapsed following the onset of paralysis, and/or until an intensive trial of rehabilitation by voice therapy has been given since many patients are capable of overcoming their vocal disability.

In bilateral laryngeal paralysis. In vocal disorders of psychogenic origin. In the presence of foreign bodies in the larynx (e.g. fragments of shells or bullets).

In the presence of an acute inflammation, infection or inadequately controlled malignancy, or a rapidly advancing disease, especially when these are in the laryngeal or upper respiratory tract area.

Warnings: Intra-cordal injection is a delicate procedure and should be conducted with precision and great caution. This product should be used only by trained ENT surgeons.

General anaesthesia is not advisable. Over-sedation may lead to an unco-operative patient and difficult airway problems. Intravascular injections must be avoided. Likewise, over-injection should be avoided.

It is safer to under-inject the involved cord than to over-inject because treatment may be repeated at a later time. If the procedure is followed by upper respiratory tract inflammatory changes in excess of the reaction expected at the site of injection, diagnostic and therapeutic procedures should be implemented. In acute fulminating reactions, steroid and antibiotic therapy may be indicated. This therapy should be at the discretion of the surgeon.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Polytef Paste for Injection is packaged in tin tubes containing 7 cc and contained in a peel-apart overwrap.

Further information Nil.

Product licence number 0508/0002.

STERILISED FASCIA LATA

Presentation Straw-coloured strip 20 cm x 6 mm consisting of bovine connective tissue from below the hide. Fascia Lata is packaged in a tubing fluid containing isopropanol and water.

Uses In surgical operations upon the human body as a substitute for human fascia.

Dosage and administration By implantation.

Contra-indications, warnings, etc There are no contra-indications or warnings.

It is recommended that Fascia Lata is rinsed in sterile water or sterile saline solution to remove tubing fluid before use.

Pharmaceutical precautions Do not subject to heat. Store in a cool place.

Legal category P.

Package quantities Three heat-sealed foil packs overwrapped and placed in a film-wrapped plastic suture box.

Further information Individual unopened packs which have been removed from the overwrap may be re-sterilised by immersion in a solution of 1% w/v formaldehyde in 93% isopropanol q.s. water. Avoid contact with caustics, chlorides and mercurials which could cause damage to the aluminium foil pack.

Product licence number 0508/5004.

STERILISED SURGICAL BONEWAX

Presentation Solid wax. A white solid, somewhat translucent when in thin layers. Comprises:

Refined white beeswax	90%
Isopropyl palmitate	10%

Uses For controlling haemorrhaging in osseous surgery and the control of the escape of fluids from osseous tissues.

Dosage and administration By implantation and application to bone as required to control haemorrhage.

Contra-indications, warnings, etc There are no contra-indications or warnings.

Pharmaceutical precautions Store under normal warehouse conditions.

Legal category P.

Package quantities Slabs (5 x 2 x 0.13 cm) of approximately 2.5 g in weight packed in a paper slide and sleeve which is overwrapped packed. The overwraps are presented in a film-wrapped plastic box containing one dozen.

Further information Avoid contact with caustics, chlorides and mercurials which could cause damage to the aluminium foil pack.

Product licence number 0508/5001.

STERILISED SURGICAL CATGUT BP – ETHICON® BRAND

Presentation An absorbable strand, with or without a needle attached, consisting of collagen derived from the intestinal tract or gut of healthy mammals uniformly twisted to produce virtually a monofilament strand with a diameter conforming to the requirements set out in the British Pharmacopoeia.

It is capable of being absorbed by living mammalian tissue but may be treated to modify its resistance to absorption.

Plain catgut is Sterilised Surgical Catgut which has not been treated to prolong its resistance to digestion. It is straw coloured.

Chromic catgut is material which has been hardened by treatment with chromium salts in trivalent form and with oxidised pyrogallol (oxidised pyrogallous acid) to prolong its resistance to absorption. It is brown coloured.

Extra chromic catgut is chromic catgut which has been treated to prolong its resistance slightly further.

Plain and chromic catgut may be dyed with a blue (indigo) dye.

Sterilised Surgical Catgut is packed in tubing fluid containing isopropanol and water.

Uses Sterilised Surgical Catgut is used in surgical operations upon the human body.

Dosage and administration By implantation.

Contra-indications, warnings, etc Should not be used in situations where a non-absorbable suture would normally be used.

Pharmaceutical precautions Do not subject absorbable surgical suture to heat. Do not rinse or soak in fluids other than the tubing fluid. Store in a cool place.

Legal category P.

Package quantities Various lengths (40 cm to 1.5 m) in heat-sealed foil packs. The foil packs are contained in a peel-open overwrap and packed into film-wrapped boxes containing one dozen sutures.

Further information Individual unopened packs which have been removed from the overwrap may be re-sterilised by immersion in a solution of 1% w/v formaldehyde in 93% isopropanol q.s. water. Avoid contact with caustics, chlorides and mercurials which could cause damage to the aluminium foil pack.

Product licence number 0508/5002.

STERILISED SURGICAL COLLAGEN

Presentation An absorbable strand of re-constituted collagen with or without a needle attached, or an absorbable tape with or without a needle attached. Available plain or chromicised. Sterilised Surgical Collagen is packed in tubing fluid containing isopropanol and water.

Uses Used in surgical operations upon the human body.

Dosage and administration By implantation.

Contra-indications, warnings, etc Should not be used in situations where a non-absorbable suture would normally be used.

Pharmaceutical precautions Do not subject absorbable surgical suture to heat. Do not rinse or soak in fluids other than the tubing fluid. Store in a cool place.

Legal category P.

Package quantities Various lengths in heat-sealed foil packs. The foil pack is contained in a peel-open overwrap and packed into film-wrapped boxes which hold one dozen sutures, or Collagen Tape (chromic) 60 cm × 3 mm, 3 packs per box.

Further information Individual unopened packs which have been removed from the overwrap may be re-sterilised by immersion in a solution of 1% w/v formaldehyde in 93% isopropanol q.s. water. Avoid contact with caustics, chlorides and mercurials which could cause damage to the aluminium foil pack.

Product licence number 0508/5008.

ZENODERM* CORIUM IMPLANT

Presentation A white biscuit-like matrix of enzyme treated, glutaraldehyde cross-linked, lyophilised or air dried porcine dermis. All non-collagenous elements are removed by immersion in a proteolytic enzyme whilst glutaraldehyde treatment crosslinks the collagen for strength. Individual sheets are cut to various sizes and thicknesses depending upon their ultimate clinical application.

Uses As a biological implant for tissue replacement in areas where tissue is weak, deficient or absent, e.g. in: Dural Replacement, Fascia Lata Substitute, Bladder Sling, Oro Antral Fistulae, Senile Entropion, Repair of Herniae, Perforations of the Tympanic Membrane and Retropubic Sling.

Dosage and administration By implantation.

Contra-indications, warnings, etc No situation has presented, to date, in the areas listed above, where the use of the material is contra-indicated. Supplied sterile, Zenoderm Corium Implant should not be re-sterilised. Open unused Zenoderm implant should be discarded.

Pharmaceutical precautions Under normal storage conditions, a shelf life of 5 years is recommended for Zenoderm Corium Implant. It should be stored in a cool place and not subjected to heat.

Legal category P.

Package quantities Supplied sterile in double peel apart overwrap envelopes (foil backing transparent fronts), Zenoderm Corium Implant is available in the following sizes, packaged 5 sheets per box.

25 cm × 12 cm × 0.6 mm	(ZD 6251)
10 cm × 10 cm × 0.3 mm	(ZD 3101)
30 cm × 2 cm × 0.6 mm	(ZD 6301)
20 cm × 1.5 cm × 0.6 mm	(ZD 6201)
30 cm × 1.5 cm × 0.6 mm	(ZD 6311)
10 cm × 5 cm × 0.6 mm	(ZD 6101)

Further information Zenoderm Corium Implant is crosslinked in a buffered solution of glutaraldehyde then freeze or air dried before sterilisation by gamma irradiation. After implantation into the human body Zenoderm is gradually replaced by host tissue.

Product licence number 0508/0007.

***Trade Mark**

BCG VACCINE (INTRADERMAL)

Presentation Multidose ampoules containing a white freeze-dried pellet which easily disperses to form an opalescent liquid on reconstitution. This vaccine is a suspension containing living *Bacillus Calmette-Guérin*, a bovine strain of tubercle bacillus which has been attenuated by growth on a special medium.

Development of the culture medium by Glaxo research has resulted in a vaccine which, in the dry state, resists the effects of heat.

This vaccine complies with the specifications for *Bacillus Calmette-Guérin* Vaccine BP, and *Vaccinum Tuberculosis* (BCG) *Cryodesiccatum* (Ph Eur), and is of standardised potency.

Uses BCG Vaccine induces active immunity to tuberculosis. Patients normally become Mantoux-positive after a period of eight weeks has elapsed but sometimes about 14 weeks are needed.

Dosage and administration *Adults and children over three months of age:* 0.1 ml by **intradermal** injection (subcutaneous injection should be avoided).

Neonates: 0.05 ml by **intradermal** injection.

No special precautions are necessary when opening the ampoules, as the dextran content produces a solid plug of dried vaccine which is not dispersed, despite the ampoule being sealed under reduced pressure. The vaccine must not be contaminated with any antiseptic or detergent. If alcohol is used to swab the skin, it must be allowed to evaporate before the vaccine is injected.

The solution is prepared by adding 1 ml Water for Injections or Sodium Chloride Injection BP (sterile isotonic saline) to the 1 ml multidose ampoule. When using the 5 ml multidose ampoule, 5 ml of Sodium Chloride Injection BP (not Water for Injections) should be added. Do not shake as this causes frothing. Allow to stand for one minute, then draw it into the syringe once or twice to ensure homogeneity. Once the liquid vaccine has been prepared, it should be used on the same day.

The injection site is best left uncovered to facilitate healing.

Contra-indications, warnings, etc

Contra-indications: Unless specifically indicated, BCG Vaccine should not be given to patients suffering from generalised eczema, infective dermatoses, hypogammaglobulinaemia, or to those with a history of deficient immunity, particularly to bacterial infections. The same applies to patients being treated with antimetabolites, irradiation, systemic corticosteroids, or any substance that depresses the immune response. The effect of BCG vaccine may be exaggerated in these patients, and a more generalised infection is possible.

Tuberculin-positive patients, i.e. those in Heaf grades 2 to 4, or with induration greater than 5 mm in diameter in the Mantoux test, should not receive BCG Vaccine.

Pregnancy: When, however, there is a risk of tuberculous

infection, the importance of vaccination may outweigh the possible risk of BCG to the fetus.

Warnings: BCG Vaccine may be given at the same time as oral poliomyelitis vaccine. With other live vaccines it is preferable to allow an interval of three weeks between administration of BCG and the other vaccine, but the interval can be reduced to 10 days if a longer period is not available. In neonates concomitant administration of BCG and smallpox vaccines is effective, but could result in ulceration of both arms for up to three weeks, as different arms must be used.

In general, vaccines containing toxoids or killed organisms should be given at least seven days before BCG Vaccine, or 10 days after. However, diphtheria/tetanus vaccine has been given at the same time as BCG Vaccine (but in different arms) with satisfactory results.

Any prepared vaccine remaining at the end of the day should be discarded, and preferably incinerated or treated with a disinfectant such as strong hypochlorite solution.

Side-effects: Occasionally an excessive response to BCG Vaccine results in a discharging ulcer. Frequently this is attributable to inadvertent subcutaneous injection, or to excessive dosage. The ulcer should be encouraged to dry by avoiding abrasion, e.g. by tight clothes. Waterproof dressings should not be used. If the ulcer persists, it can be treated by application of a cream containing neomycin and a corticosteroid, or by local application of isoniazid powder.

In the rare cases of severe local reactions with abscess formation, aspiration should be carried out, perhaps with streptomycin replacement. Enlargement of axillary lymph glands is unlikely, except occasionally in young infants.

Overdosage: If gross overdosage occurs, and there is reason to suspect the development of a more generalised infection with BCG, systemic treatment with isoniazid should be given.

Pharmaceutical precautions Protect from light and keep in a refrigerator at a temperature below 10°C, but avoid freezing ampoules of diluent. Refrigeration during actual delivery is not essential but the vaccine should be kept as cool as possible.

Legal category POM.

Package quantities 1 ml multidose ampoules in boxes of 10.

Composite pack of five 1 ml multidose ampoules with five 1 ml ampoules of Water for Injections.

5 ml multidose ampoules with 5 ml ampoules of Sodium Chloride Injection BP are available to United Kingdom Health Authorities and hospitals through Department of Health and Social Security contract.

Further information No batch of vaccine is released until it has been shown to resist a temperature of 37°C for 28 days.

Measles or rubella infection can cause tuberculin positive patients to revert temporarily to tuberculin negative.

BCG Vaccine (Intradermal) has also been given by jet injector.

Product licence number 0004/0245.

BCG VACCINE (PERCUTANEOUS)

Presentation Multidose ampoules containing a freeze-dried white pellet which is easily dispersed to form an opalescent suspension on reconstitution. This vaccine contains dextran and living *Bacillus Calmette-Guérin* (BCG) with a higher viable bacterial count than BCG Vaccine (Intradermal). The BCG is an attenuated form of a bovine strain of tubercle bacillus. This vaccine complies with the specification for Percutaneous BCG Vaccine BP, and is of standardised potency.

Uses Percutaneous BCG Vaccine induces active immunity to tuberculosis. Patients normally become Mantoux-positive after a period of eight weeks has elapsed, but sometimes up to 14 weeks are needed.

Dosage and administration Percutaneous BCG Vaccine is used with a multiple puncture apparatus equipped with not less than 20 needles giving reliable penetration of the skin to a depth of 2 mm. Ethyl or isopropyl alcohol may be used to prepare the skin, which must be dry before the vaccine is used.

With a dry syringe add 0.3 ml of Water for Injections or Sodium Chloride Injection to the ampoule of BCG, and allow to stand for about one minute to allow a suspension to form. Do NOT shake, as this causes rothing. A small amount of the suspension is spread on the skin by means of a glass rod, platinum loop or spatula. The treated area of skin is then immediately punctured with the multiple puncture apparatus.

Once the vaccine has been prepared for use, it should be used forthwith; any remaining at the end of the day should be discarded after boiling or treatment with a disinfectant, e.g. strong hypochlorite solution.

The injection site is best left uncovered; waterproof dressings are particularly undesirable. The multiple puncture apparatus should be sterilised according to the maker's instructions. Any alcohol or ether used should be burnt off before the apparatus is used, and IT MUST BE ALLOWED TO COOL before use. Detergents or antiseptics should not be used.

Contra-indications, warnings, etc

Contra-indications: Unless specifically indicated, percutaneous BCG Vaccine should not be given to patients suffering from generalised eczema, infective dermatoses, hypogammaglobulinaemia or a history of deficient immunity, especially to bacterial infections. This vaccine is also contra-indicated in patients treated with antimetabolites, irradiation, systemic corticosteroid, or any substance which depresses the immune response.

Tuberculin-positive patients, i.e., those in Heat grades 1 to 4 or with induration greater than 5 mm in diameter with the Mantoux test, should not receive percutaneous BCG vaccine.

Pregnancy: When, however, there is a risk of tuberculous infection, the importance of vaccination may outweigh the possible risks of BCG to the fetus.

Warnings: Percutaneous BCG Vaccine must NOT be given by intradermal injection or by Dermojet.

BCG Vaccine may be given at the same time as oral poliomyelitis vaccine. With other live vaccines it is preferable to allow an interval of three weeks between administration of BCG and the other vaccine, but the interval can be reduced to 10 days if a longer period is not available. In general, vaccines containing toxoids or killed organisms should be given at least seven days before BCG vaccine, or 10 days after.

Any prepared vaccine remaining at the end of the day should be discarded, and incinerated or treated with a disinfectant such as strong hypochlorite solution.

Side-effects: Occasionally an excessive response to percutaneous BCG vaccine results in a discharging ulcer. This should be encouraged to dry by avoiding abrasion, e.g. by tight clothes. Waterproof dressings should not be used. If the ulcer persists, it can be treated by application of a cream containing a corticosteroid, with neomycin to prevent secondary infection, or by local application of isoniazid powder.

In the rare cases of severe local reactions with abscess formation, aspiration should be carried out, perhaps with streptomycin replacement. Enlargement of axillary lymph glands is unlikely, except occasionally in young infants.

Overdosage: If gross overdosage occurs, and there is reason to suspect the development of a generalised infection with BCG, systemic treatment with isoniazid should be given.

Pharmaceutical precautions Protect from light and keep in a refrigerator at a temperature below 10°C. Refrigeration during actual delivery is not essential, but the vaccine should be kept as cool as possible.

Legal category POM.

Package quantities Multidose ampoules in boxes of 10.

Further information Infections such as measles or rubella may cause tuberculin-positive patients to revert temporarily to tuberculin-negative.

Product licence number 0004/0247.

NEPENTHE* INJECTION

Presentation A clear, colourless, sterile solution containing the equivalent of 0.84% w/v (4.2 mg/0.5 ml) anhydrous morphine of which 0.05% w/v is derived from Papaveretum BPC and 0.79% w/v from Morphine Hydrochloride BP.

Uses To relieve severe pain, especially when it causes anxiety and/or sleeplessness.

Dosage and administration

Not to be used for Children under 6 year of age.

6-12 years: Maximum single dose 0.5-1.0 ml.

Adults: Usual single dose 1-2 ml but not to be repeated more than four hourly.

Nepenthe Injection should be administered by the subcutaneous or intramuscular routes using a syringe graduated in 1/100ths of a ml. It must not be given intravenously.

When doses of fractional of a ml are prescribed special care should be taken in view of the small volumes involved.

Contra-indications, warnings, etc Nepenthe Injection should not be given concurrently with other opiates,

with monoamine oxidase inhibitors, nor within two weeks of discontinuation of treatment with them.

Nepenthe Injection is contra-indicated in respiratory depression and obstructive airways disease. Use with care in the elderly. Safety in pregnancy has not been established. Use with caution in myxoedema and chronic hepatic disease. Administration in labour may cause respiratory depression in the new born infant.

Tolerance and dependence may occur and nausea and vomiting may be troublesome.

Effects of overdosage and their treatment: Signs of morphine overdosage include pin-point pupils, depressed respiration and coma. In severe poisoning there may be dilatation of the pupils, shock, severe respiratory depression and pulmonary oedema.

Naloxone, nalorphine or levallorphan tartrate may be given as an antidote.

Pharmaceutical precautions Protect from light.

Legal category POM: MDA.

Package quantities Ampoules of 0.5 ml in boxes of 5.

Further information Any requests for further information should be made to Evans Medical Limited, Beaconsfield, Buckinghamshire HP9 2JH. Telephone Beaconsfield 6111.

Product licence number 0039/0063R.

NEPENTHE* ORAL SOLUTION

Presentation A brown, bright solution with characteristic odour containing 0.84% w/v anhydrous morphine of which 0.79% w/v is derived from Morphine alkaloid and 0.05% w/v is derived from Tincture of Opium BP. 1 ml contains 8.4 mg anhydrous morphine.

Uses To relieve severe pain, especially when it causes anxiety and/or sleeplessness.

Dosage and administration Nepenthe Oral Solution is for use as an ingredient in the preparation of narcotic analgesic mixtures. The recommended diluent is Syrup BP.

This product must always be diluted when being dispensed by the pharmacist and the dosage expressed in units of 5 ml.

Children under 1 year: not recommended.

1–5 years: 0.25–0.5 ml maximum single dose.

6–12 years: 0.5–1.0 ml maximum single dose.

Adults: Usual single dose 1–2 ml, not to be repeated more often than four hourly.

Contra-indications, warnings, etc

Nepenthe Oral Solution should not be given concurrently with other opiates, with monoamine oxidase inhibitors nor within two weeks of discontinuation of treatment with them.

Nepenthe Oral Solution is contra-indicated in respiratory depression and obstructive airways disease. Use with care in the elderly. Safety in pregnancy has not been established. Use with caution in myxoedema and chronic hepatic disease. Administration in labour may cause respiratory depression in the new born infant.

Tolerance and dependence may occur and nausea and vomiting may be troublesome.

Effects of overdosage and their treatment: Signs of morphine overdosage include pin-point pupils, de-

pressed respiration and coma. In severe poisoning there may be dilatation of the pupils, shock, severe respiratory depression and pulmonary oedema.

Gastric lavage should be performed as soon as possible after ingestion and intensive supportive therapy carried out.

Naloxone, nalorphine or levallorphan tartrate may be given as an antidote.

Pharmaceutical precautions Nepenthe Oral Solution should be diluted with Syrup BP. Any diluted portion not used within four weeks should be discarded. Protect from light. Nepenthe Oral Solution is compatible with Ethanol BP, Chloroform Spirit BP and Glycerol BP. It is incompatible with alkalis.

Because of the volatile nature of the solvent, Nepenthe Oral Solution should be stored in a cool place and the bottle should be tightly closed. If evaporation is thought to have occurred during storage, the solution must not be used.

Legal category POM: MDA.

Package quantities Bottle of 100 ml.

Further information Any requests for further information should be made to Evans Medical Limited, Beaconsfield, Buckinghamshire HP9 2JH. Telephone Beaconsfield 6111.

Product licence number 0039/0062R.

STREPTOMYCIN SULPHATE BP

Presentation Streptomycin sulphate is supplied in vials as a white sterile powder for preparation of Streptomycin Sulphate Injection BP.

Uses Streptomycin has antibacterial activity particularly against *Mycobacterium tuberculosis*, *Klebsiella pneumoniae* and *Escherichia coli*.

Streptomycin may be used in the treatment of: tuberculosis; non-tuberculous infections, including chronic respiratory infections, septicaemia and bacterial endocarditis (usually in conjunction with penicillin); pneumonia due to *Klebsiella pneumoniae*; infections with *Escherichia coli*, particularly of the urinary tract; tularaemia and plague; brucellosis (normally in conjunction with a tetracycline).

Dosage and administration *Tuberculosis: Adults.* Commonly 1 g daily, but in patients over 40 years of age 0.75 g daily by intramuscular injection may be appropriate. Streptomycin is given in conjunction with other antituberculous drugs. The injection should be given deeply into muscle, and the site changed for each injection. A 1 g dose is usually dissolved in 2 or 3 ml of Water for Injections.

Children: Usually 30 mg/kg (13.6 mg/lb) body weight daily up to 1 g a day by intramuscular injection.

Tuberculous meningitis: Intramuscular dosage 30–40 mg/kg (13.6–18 mg/lb) body weight up to 1 g a day. In addition to this streptomycin may be given intrathecally: adults, 50 mg a day; infants and children, 1 mg per kilogram body weight daily. The antibiotic is dissolved in Sodium Chloride Injection, using 5 ml for infants and 10 ml or more for children and adults. The concentration of streptomycin in the injection must not exceed 5 mg/ml. After withdrawal of an equal volume of cerebrospinal fluid, the solution is injected slowly, taking at least 1 l

minutes. An injection may be given once a day for 10 days, perhaps followed by a dose on three alternate days.

Use of a sterile disposable membrane filter of 0.45 micron pore size is convenient to ensure clarity of the solution.

Non-tuberculous infections. Adults: Usually 1 g a day by intramuscular injection for three to seven days.

Children: 22–40 mg/kg (10–18 mg/lb) body weight daily. Divided doses are often used.

N.B. In urinary-tract infections the urine should be kept alkaline.

Contra-indications, warnings, etc

Contra-indications: Allergy to streptomycin.

Diseases of the ear, particularly suppurative otitis media and labyrinthine disturbances.

Precautions: In the presence of actual or suspected renal insufficiency, treatment of non-tuberculous infections may start with a dose of 250–500 mg streptomycin. No further dose should be given until the blood level has fallen to 20 mcg/ml or less (*Brit. Med. J.* 1963, 1, 1393).

In tuberculous patients over 60 years of age, the serum level of streptomycin 24 hours after injection should not exceed 1 mcg/ml. It is important to repeat this estimation several times in the early weeks of treatment (*Brit. Med. J.* 1963, 1, 1527).

Skin sensitisation may occur in persons handling the antibiotic and care should be taken to avoid contact with the substance. Use of rubber gloves is recommended.

Side-effects: Ototoxicity: Some impairment of vestibular function (less often of auditory function) can occur, particularly with prolonged or intensive therapy, in the presence of renal dysfunction, and in the elderly patient. Prolonged streptomycin therapy given during pregnancy can cause deafness and vestibular dysfunction in the child.

Sensitivity: Occasional allergic-type reaction, rarely severe, often responding to antihistamine treatment. Anaphylactic reaction is rarely reported.

Overdosage: Streptomycin can be removed from the body by haemodialysis.

Pharmaceutical precautions Sterile solutions of streptomycin should be used as soon as possible but they can be kept for up to 28 days in a refrigerator (below 4°C). Limited storage (up to seven days) is permissible in a cool place (below 20°C) if protected from light.

Although solutions may discolour slightly on keeping, potency is not decreased.

Legal category POM.

Package quantities Vials each containing 1 g streptomycin base as sulphate, box of 10.

Further information To obtain fractional doses:

Volume of water to be added to 1 g vial	Streptomycin per ml of solution
4.2 ml	200 mg
3.2 ml	250 mg
1.2 ml	500 mg
1 g streptomycin in solution displaces 0.82 ml.	

Product licence number 0039/6002.

TUBERCULIN PURIFIED PROTEIN DERIVATIVE (PPD) BP

Presentation Sterile aqueous solutions for intradermal

injection containing Tuberculin PPD BP are prepared from human strains of *Mycobacterium tuberculosis*.

Use As a diagnostic test for hypersensitivity to tubercle bacilli.

Dosage and administration

1. **Mantoux Test:** The Mantoux test enables an estimate to be obtained of the degree of hypersensitivity of a particular patient. It consists of injecting intradermally ready diluted Tuberculin PPD.

First, clean the skin of the volar surface of the left forearm with acetone or ether. Then using a disposable syringe inject 0.1 ml so that a weal 7 mm in diameter is raised.

The following doses are given, the second and subsequent injections being given only if a negative reaction is obtained from the previous injection.

- 0.1 ml of 10 units per ml Tuberculin dilution (1 unit).
- 0.1 ml of 100 units per ml Tuberculin dilution (10 units).
- 0.1 ml of 1,000 units per ml Tuberculin dilution (100 units).

An interval of two days is allowed between the injections. A further injection of 0.1 ml containing 1,000 units may be given if no reaction has been obtained to the third injection. Children are given one half of the above dose but the 1,000 units in 0.1 ml is not usually given. A positive reaction is characterised by an area of 6 mm or greater of palpable induration, which may sometimes be surrounded by erythema and the results should be read at 48 to 96 hours, preferably after 72 hours.

This test may be carried out and at the same time the control solution may be used to assess individual patients response to the vehicle used.

2. **Heaf test:** This test is performed using undiluted Tuberculin PPD at a strength of 100,000 units per ml. 1 ml is sufficient for 50–100 tests and in addition to the tuberculin the solution contains in each ml 0.2 g glycerol and phenol 2.5 mg, together with phosphate buffers.

Cleanse the skin as for the Mantoux test and allow to dry, then transfer undiluted tuberculin using a syringe needle or loop and smooth over a circular area of about 1 cm in diameter. Using the Heaf multiple puncture apparatus set the apparatus to give a puncture of 1 mm for children under the age of two years or 2 mm for older children and adults. Holding the apparatus at right angles to the skin, place the end plate firmly and evenly in the centre of the film of tuberculin and press the handle to release the needles. No dressing need be applied and the gun should be sterilised after each application or a disposable end plate should be used.

The test should be read at 3 to 10 days. A positive result should be recorded only when there is palpable induration around at least four puncture points. The induration is best felt by passing the finger lightly over the punctures, and if no resistance is felt, a negative result should be recorded.

Four grades of positive response are recognised.

- at least 4 small indurated papules
- an indurated ring formed by confluent papules
- a solid induration 5 to 10 mm wide
- induration over 10 mm wide.

For further information on methods of use see DHSS leaflet No. 322/BCG (1972).

Contra-indications, warnings, etc Temporary diminution of skin sensitivity to tuberculin may occur after

ultra-violet light treatment, during treatment with corticosteroids or immunosuppressive agents, and for 4 weeks or longer following measles or measles vaccination.

Tuberculin can cause a severe acute local reaction in some individuals if the solution is allowed to come into contact with open cuts, the eyes and the mouth.

The affected area should be washed with copious quantities of water followed, if necessary, by local corticosteroids.

The potency of tuberculins may be affected if they are diluted with diluents which differ in composition from the vehicle used in their preparation.

Pharmaceutical precautions Dilutions of tuberculins do not retain their potency for long periods and should therefore be ordered only as required and used before the expiry date shown on the package. Use contents of ampoule at once or within one hour provided adequate aseptic precautions are taken. Any unused solution should be disposed of by flushing away to waste with copious water. Care should be taken to avoid contamination of the ampoule contents.

Legal category POM.

Package quantities *Undiluted*: – ampoules of 1 ml in packs of 5.

Dilutions: – ampoules of 1 ml in packs of 5.

Control solution: – ampoules of 1 ml in packs of 5 for Mantoux Test.

Tuberculin undiluted and Tuberculin 100 units per ml (dilution 1 in 1,000), 5 × 1 ml ampoule packs are available to United Kingdom Health Authorities and hospitals through Department of Health & Social Security Contract.

Further information Nil.

ECOSTATIN* CREAM, LOTION, POWDER, SPRAY POWDER, AND SPRAY SOLUTION

Presentation Cream: White cream containing 1% w/w econazole nitrate.

Lotion: Milky white homogeneous lotion containing 1% w/w econazole nitrate.

Powder and spray powder: White powder containing 1% w/w econazole nitrate in a talc base.

Spray solution: Alcoholic solution containing 1% w/w econazole nitrate.

Uses Actions: Econazole nitrate is a broad spectrum antifungal agent, active against dermatophytes (*Trichophyton rubrum*, *Trichophyton mentagrophytes*, *Epidermophyton floccosum* and *Malassezia furfur*); pathogenic yeasts; *Candida albicans* and other *Candida* species. Also active against some Gram-positive bacteria, e.g. staphylococci and streptococci.

Indications All fungal skin infections due to dermatophytes (e.g. *Trichophyton* species), yeasts (e.g. *Candida* species), moulds and other fungi. These include ringworm (tinea) infections, athlete's foot, paronychia, pityriasis versicolor, erythrasma, intertrigo, fungal nappy rash, candidal vulvitis and candidal balanitis.

Dosage and administration Cream: To be massaged gently into the affected and surrounding skin area morning and evening. The cream is particularly suitable for moist or weeping lesions.

Lotion: To be applied twice daily to the affected and surrounding skin area. In the treatment of fungal infections of the nail, apply once daily with an occlusive dressing.

Powder and spray powder: To be applied to the affected area twice daily. The powder is particularly suitable for use in skin folds, e.g. inguinal and interdigital.

Spray solution: To be applied twice daily. See precautions.

All preparations are suitable for topical application to both adults and children.

Clinical improvement usually occurs promptly; however, complete disappearance of the symptoms of the disease may require prolonged treatment. Therapy should continue for several days following both clinical and mycological cure in order to prevent relapse.

Contra-indications, warnings, etc

Contra-indications: None known.

Precautions: Ecostatín cream, lotion, powder, spray powder or spray solution should not be used in or near the eyes. Ecostatín spray solution should not be used on mucous membranes. Care should be taken in the presence of eczematous dermatitis.

Side-effects: Ecostatín is well tolerated. Side-effects are

limited to occasional local irritation manifested by erythema, burning or stinging sensation, and pruritus.

Pharmaceutical precautions *Storage:* Cream, lotion, powder: Store at room temperature.

Spray powder, spray solution: Store in a cool place.

Legal category P.

Package quantities *Ecostatín cream:* Tubes of 30 g and 15 g.

Ecostatín lotion: 30 ml.

Ecostatín powder: 30 g.

Ecostatín spray powder: 200 g.

Ecostatín spray solution: 150 g.

ECOSTATIN* PESSARIES AND TWIN PACK

Presentation Pessaries: White, opaque, oval pessaries each containing 150 mg econazole nitrate in an hydro-genated vegetable oil base.

Twin pack: Three Ecostatín pessaries with applicator plus 15 g Ecostatín cream (containing 1% w/w econazole nitrate).

Uses Actions: Econazole nitrate has a broad spectrum of antifungal activity. It is highly active against *Candida albicans* and other *Candida* species and is effective in controlling infections of the vagina and vulva caused by such organisms (thrush).

Indications: Vulvovaginal candidosis. In addition to vaginal treatment the Twin Pack contains cream for topical application to the anogenital area.

Dosage and administration Pessaries: One pessary to be inserted at bedtime for three consecutive nights. Administration should be continued even if menstruation occurs, and despite the disappearance of signs and symptoms of the infection.

The pessary should be inserted high into the vagina while the patient is supine.

Cream: The cream is applied twice daily, in the morning and evening, to the anogenital area.

Note: To prevent re-infection with *Candida*, the male consort should be treated concurrently with Ecostatín cream, applied twice daily to the external genital area during the treatment period.

Although a three day course of therapy usually suffices, it may be necessary to institute a second course of therapy.

Contra-indications, warnings, etc

Contra-indications: None known.

Precautions: Ecostatín pessaries are effective in the candidal vaginitis associated with pregnancy. However, as with other agents, Ecostatín should not be used during the first trimester of pregnancy unless the physician deems its use essential for the welfare of the patient. In pregnancy, extra care should be taken in using an applicator to prevent the possibility of mechanical trauma. Avoid contact between contraceptive diaphragms and this product, since the rubber may be damaged by the preparation.

Side-effects: Patients may rarely complain of discomfort; this is usually transitory and disappears with continued treatment. Seldom is it necessary to discontinue econazole pessary treatment.

Ecostatín cream is well tolerated. Side-effects are limited to occasional local irritation manifested by erythema, burning or stinging sensation, and pruritus.

Pharmaceutical precautions *Storage:* Store at room temperature.

Legal category Cream P.
Pessaries POM.

Package quantities *Pessaries:* Pack of three pessaries with applicator.

Twin pack: Three pessaries with applicator plus 15 g cream.

Further information Nil.

Ecostatín Cream 0085/0014

HALCICOMB* CREAM

Presentation Pale yellow in a vanishing cream base, containing in each gram the following:

Halcinonide	0.1%
Neomycin (as sulphate)	0.25%
Nystatin	100,000 units

Uses *Actions:* Halcinonide is a potent corticosteroid with rapid anti-inflammatory, anti-pruritic and anti-allergic actions.

Neomycin provides comprehensive antibacterial therapy against a wide range of Gram-negative and Gram-positive bacteria, including those responsible for most bacterial skin infections.

Nystatin is an anti-fungal antibiotic, active against a wide range of yeasts and yeast-like fungi, including *Candida albicans*.

Indications: The topical treatment of superficial bacterial infections, cutaneous candidosis and dermatological conditions known to respond to topical steroid therapy when threatened or complicated by bacterial or candidal superinfection. These include: atopic eczema, contact eczema, follicular eczema, infantile eczema, otitis externa, anogenital pruritus (pruritus ani et vulvae), nummular eczema, post-traumatic infective eczema, seborrhoeic or flexural eczema, neurodermatitis, psoriasis.

Dosage and administration *Adults and children:* Apply to the affected areas two to three times daily.

Contra-indications, warnings, etc *Contra-indications:* In tuberculous and most viral lesions of the skin, particularly herpes simplex, vaccinia and varicella. Also in fungal lesions not susceptible to nystatin. It is not intended for ophthalmic use, nor should it be applied to the external auditory canal of patients with perforated eardrums.

Precautions: Since the use of occlusive dressings may increase the risk of sensitivity, such dressings should be avoided. In infants long-term continuous topical steroid therapy should be avoided. Adrenal suppression may occur, even without occlusion.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to humans has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for long periods.

Side-effects: Halcinonide and nystatin are well tolerated and local irritation is not common. Sensitivity reactions to neomycin may occur.

Pharmaceutical precautions *Storage:* Store at room temperature; avoid freezing.

Dilution: Not recommended, as this would reduce the concentration of the antibiotics to below therapeutic levels.

Consult manufacturers for advice if dilution required.

Legal category POM.

Package quantities Tubes of 25 g.

Further information Nil.

Product licence number 0085/0009.

MULTILIND* OINTMENT

Presentation Pale yellow ointment containing 100,000 iu nystatin per gram in an emollient base thickened with 5% w/w zinc oxide.

Uses *Actions:* Nystatin is an antifungal antibiotic active against a wide range of yeasts and yeast-like fungi, including *Candida albicans*.

Indications: For the treatment of cutaneous and mucocutaneous mycoses, especially those caused by *C. albicans*. Multilind ointment is particularly indicated for the treatment of napkin rash where super-infection with *C. albicans* has occurred.

Dosage and administration To be applied liberally to the affected area two to four times daily.

Contra-indications, warnings, etc

Contra-indications: There are no known contra-indications or special precautions for topical application of nystatin.

Side-effects: There have been no substantiated reports of sensitivity associated with the topical use of nystatin.

Pharmaceutical precautions *Storage:* At room temperature. Avoid freezing.

Dilution: Nystatin products should not be diluted as this may reduce therapeutic efficacy.

Legal category POM.

Package quantities Tubes of 30 g and 100 g.

Further information Nil.

Product licence number 0085/0015.

ADRIAMYCIN®

Presentation Sterile, pyrogen-free, orange-red, freeze-dried powder in vials of 10 mg and 50 mg each containing doxorubicin hydrochloride and lactose.

Uses Antimitotic and cytotoxic. Adriamycin has been used successfully to produce regression in a wide range of neoplastic conditions including acute leukaemias, lymphomas, soft-tissue and osteogenic sarcomas, paediatric malignancies and adult solid tumours, in particular breast and lung carcinomas.

Adriamycin is frequently used in combination chemotherapy regimens involving other cytotoxic drugs.

Dosage and administration For reconstitution the contents of the 10 mg vial may be dissolved in 5 ml Water for Injections or Sodium Chloride Injection and those of the 50 mg vial in 25 ml of the same solvents.

Intravenous administration: This is the most frequently used route of administration. The reconstituted solution is given via the tubing of a freely-running intravenous infusion, taking two to three minutes over the injection. This technique minimises the risk of thrombosis or perivenous extravasation which can lead to severe cellulitis and vesication. Commonly used acceptable solutions are Sodium Chloride Injection, Dextrose Injection 5% or Sodium Chloride and Dextrose Injection.

Dosage is usually calculated on the basis of body surface area. On this basis, 60–75 mg/m² may be given every three weeks when Adriamycin is used alone. If it is used in combination with other antitumour agents having overlapping toxicity, the dosage of Adriamycin may need to be reduced to 30–40 mg/m² every three weeks. If dosage is to be calculated on the basis of body weight, 1.2–2.4 mg/kg should be given as a single dose every three weeks.

It has been shown that giving Adriamycin as a single dose every three weeks greatly reduces the distressing toxic effect, mucositis; however, there are still some who believe that dividing the dose over three successive days (0.4–0.8 mg/kg or 20–25 mg/m² on each day) gives greater effectiveness even though at the cost of higher toxicity.

Dosage may need to be reduced for patients who have had prior treatment with other cytotoxics and for the elderly.

Intra-arterial administration: More recently, intra-arterial injection has been used in attempts to produce intense local activity while keeping the total dose low and therefore reducing general toxicity. It should be emphasised that this technique is potentially extremely hazardous and can lead to widespread necrosis of the perfused tissues unless due precautions are taken. Intra-arterial injection should only be attempted by those fully conversant with the published literature on the method.

Intravesicular administration: Adriamycin is being increasingly used by intravesicular administration for the

treatment of transitional cell carcinoma, papillary bladder tumours and carcinoma in situ. It should not be employed in this way for the treatment of invasive tumours which have penetrated the bladder wall. It has also been found useful to instil Adriamycin into the bladder at intervals after transurethral resection of a tumour in order to reduce the probability of recurrence. While at present many regimens are in use, making interpretation difficult, the following may be helpful guides:

The concentration of Adriamycin in the bladder should be 50 mg per 50 ml.

To avoid undue dilution with urine, the patient should be instructed not to drink any fluid in the 12 hours prior to instillation. This should limit urine production to approximately 50 ml per hour.

Exposure to the drug solution for one hour is generally adequate and the patient should be instructed to void at the end of this time.

Contra-indications, warnings, etc Adriamycin is intended for use under the direction of those experienced in cytotoxic therapy.

Dosage should not be repeated in the presence of bone-marrow depression or buccal ulceration. The latter may be preceded by premonitory buccal burning sensations and repetition in the presence of this symptom is not advised. Cardiotoxicity may be manifested in tachycardia and ECG changes, routine ECG monitoring is recommended and caution should be exercised in patients with impaired cardiac function.

A cumulative dose of 550 mg/m² should be exceeded only with extreme caution; above this level the risk of irreversible congestive cardiac failure appears to increase greatly.

Haematological monitoring should be undertaken regularly in both haematological and non-haematological conditions in view of the possibility of bone-marrow depression which may occur around ten days from the time of administration. Alopecia is usual and nausea, vomiting and diarrhoea may occur. The risk of thrombophlebitis at the injection site may be minimised by following the procedure for administration recommended above.

Adriamycin imparts a red colour to the urine, particularly to the first specimen passed after the injection, and patients should be advised that this is no cause for alarm.

In the presence of liver impairment, the dosage of Adriamycin should be reduced, moderate dysfunction (bilirubin 1.2–3 mg/100 ml or BSP retention 9–15%) requires a 50% reduction of the dose while severe impairment (bilirubin > 3 mg/100 ml or BSP retention > 15%) necessitates a dose reduction of 75%.

There is no conclusive information as to whether Adriamycin may adversely affect human fertility, or cause teratogenesis. Experimental data, however, suggest that Adriamycin may harm the foetus. This product should not normally be administered to patients who are pregnant or to mothers who are breast-feeding.

Accidental contact with the skin or eyes should be treated immediately by copious lavage with water or soap and water, or, if available, sodium bicarbonate solution.

Overdosage: Single doses of 250 mg and 500 mg of Adriamycin have proved fatal. Such doses may cause acute myocardial degeneration within 24 hours and severe myelosuppression, the effects of which are greatest between 10 and 15 days after administration. Treatment should aim to support the patient during this period and should utilise such measures as blood transfusions and reverse barrier nursing. Delayed cardiac failure may occur up to six months after the overdose. Patients should be observed carefully and should signs of cardiac failure arise, be treated along conventional lines.

Pharmaceutical precautions Reconstitution occasionally results in the formation of a gelatinous mass which will completely dissolve on further shaking. The resulting solution may be stored for up to 24 hours at room temperature or 48 hours at 4°C without significant deterioration. Prolonged contact with any solution of an alkaline pH should be avoided as it will result in hydrolysis of the drug. Adriamycin should not be mixed with heparin as a precipitate may form and it is not recommended that Adriamycin be mixed with other drugs. Exposure to sunlight can result in degradation.

It is recommended that personnel handling Adriamycin should wear protective gloves.

Legal category POM.

Package quantities 10 mg and 50 mg vials for injection.

Further information Nil.

Product licence number 3433/0025.

CYCLOPHOSPHAMIDE

Presentation White, biconvex, sugar-coated tablets containing cyclophosphamide monohydrate 50 mg.

Cyclophosphamide for injection is a sterile white powder in clear glass vials, with rubber caps and aluminium seals, containing 100 mg, 200 mg, 500 mg or 1,000 mg of cyclophosphamide monohydrate with sodium chloride.

Uses Alkylating, antineoplastic agent. Cyclophosphamide has been used successfully to induce and maintain regressions in a wide range of neoplastic conditions, including leukaemias, lymphomas, soft tissue and osteogenic sarcomas, paediatric malignancies and adult solid tumours; in particular, breast and lung carcinomas.

Cyclophosphamide is frequently used in combination chemotherapy regimens involving other cytotoxic drugs.

Dosage and administration The dosage regimen should be tailored to the individual requirements of the patient, depending on his general condition, concurrent therapy, the type and state of tumour, and the patient's response. Three sample regimens may serve as guides:

<i>Low dose</i>	80 to 240 mg/m ² (2 to 6 mg/kg) as a single dose weekly i.v., or in divided doses orally.
<i>Medium dose</i>	400 to 600 mg/m ² (10 to 15 mg/kg) as a single dose weekly i.v.
<i>High dose</i>	800 to 1,600 mg/m ² (20 to 40 mg/kg) as a single dose i.v. at 10–20 day intervals.

Higher doses should be used only at the discretion of a physician experienced in cytotoxic chemotherapy.

It is recommended that the calculated dose of cyclophosphamide be reduced when it is given in combination with other anti-neoplastic agents or radiotherapy, and in patients with bone marrow depression.

Cyclophosphamide tablets should be swallowed whole, preferably on an empty stomach, but if gastric irritation is severe, they may be taken with meals.

Cyclophosphamide injection should be reconstituted with Water for Injections, 5 ml for each 100 mg of cyclophosphamide. After reconstitution the solution will remain stable at room temperature for 2–3 hours. It should be given by slow intravenous injection over a period of 2–3 minutes or into the tubing of a freely running intravenous infusion over a period of 2–3 minutes.

Contra-indications, warnings, etc Cyclophosphamide should be used only under the direction of physicians experienced in cytotoxic or immunosuppressant therapy.

Contra-indications: Hypersensitivity and haemorrhagic cystitis.

Warnings: Cyclophosphamide should be withheld in the presence of severe bone marrow depression and reduced doses should be used in the presence of lesser degrees of bone marrow depression. Single doses will produce a leucopenia which may be severe but usually returns to normal within 21 days. Regular blood counts should be performed in patients receiving cyclophosphamide. This product should not normally be administered to patients who are pregnant or to mothers who are breast-feeding. It should not normally be given to patients with severe infections and should be withdrawn if such infections become life-threatening.

Cyclophosphamide should be used with caution in debilitated patients and those with renal and/or hepatic failure. In all such cases, dosage should be reduced. Oral hypoglycaemic agents may be potentiated by cyclophosphamide.

Amenorrhoea and azoospermia often occur during treatment with cyclophosphamide but in most cases are reversible. Alkylating agents, including cyclophosphamide, have been shown to possess mutagenic, teratogenic and carcinogenic potential. Pregnancy should therefore be avoided during cyclophosphamide therapy and for three months thereafter.

Cyclophosphamide is excreted mainly in the urine largely in the form of active metabolites which may give rise to a chemical cystitis which may be haemorrhagic. Because of this, a high fluid intake should be maintained with frequent emptying of the bladder. However, cyclophosphamide may give rise to fluid retention with subsequent water intoxication. Should this arise, a diuretic may be given. Cyclophosphamide may cause myocardial toxicity, especially at high dosage.

Cyclophosphamide may induce permanent sterility in children.

Side-effects: In addition to those noted above, the following may accompany cyclophosphamide therapy: hair loss, which may be total, although generally reversible; mucosal ulceration, anorexia, nausea and vomiting, pigmentation typically affecting the palms and nails of the hands and the soles of the feet, and interstitial pulmonary fibrosis.

Overdosage: If the drug has been taken in the form of tablets, early gastric lavage may reduce the amount of

drug absorbed. In all cases, forced alkaline diuresis with copious fluid intake, using diuretics if necessary, should be employed. Patients should be observed for signs of water overload and monitored for electrolyte disturbances. Profound myelo-suppression should be anticipated and may require such measures as blood transfusions, antibiotic therapy and reverse barrier nursing. Bleeding, possibly severe, may occur from the bladder and gastro-intestinal tract.

Pharmaceutical precautions *Tablets:* Store in a cool dry place and protect from light.

Injection: Store in a cool place and protect from light.

If heated above 32°C, cyclophosphamide may decompose to a damp-looking gel. It is, therefore, recommended that this product is never stored where heat build-up may occur such as near radiators, etc.

Legal category POM.

Package quantities

Tablets: Containers of 100 and 250 tablets of 50 mg.

Injection:

Vials of 100 mg in packs of 6 and 24.

Vials of 200 mg in packs of 6 and 24.

Vials of 500 mg in packs of 6.

Vials of 1,000 mg in packs of 6.

Each vial contains dry powder for reconstitution.

Further information Nil.

EUHYPNOS®

Presentation Green soft gelatin capsules, marked '10' on white, containing temazepam 10 mg in solution.

Uses Euhypnos is indicated for the short-term treatment of sleep disturbances.

It is particularly suitable for patients with transient sleep disorders in whom the re-establishment of normal sleep patterns is anticipated following the resolution of precipitating factors.

Euhypnos is also indicated for pre-medication for minor surgical and investigatory procedures, especially in the case of out-patients.

Dosage and administration *Insomnia - Adults:* One or three capsules by mouth on retiring. A dose of two capsules will be found satisfactory for most patients. This may be increased to four or six capsules in patients who do not respond to the lower dose.

Elderly: Half the normal adult dose may be sufficient for a therapeutic response in the elderly (see Warnings and Adverse Effects).

Children: Not recommended.

Pre-medication: 2 to 4 capsules from half an hour to one hour prior to surgery or investigatory procedures.

Contra-indications, warnings, etc *Contra-indications:* Known sensitivity to benzodiazepines. Acute pulmonary insufficiency.

Warnings: Although hangover effect is uncommon, patients should be warned against driving or operating

dangerous machinery if so affected. Doses of 30 mg and above are more likely to cause hangover effects to persist into the following day than lower doses, particularly in patients unused to hypnotics and in the elderly. As with all compounds which have an effect on the CNS, patients should be advised not to consume alcohol whilst taking Euhypnos.

Use in pregnancy: There is no evidence as to drug safety in human pregnancy, nor is there evidence from animal work that the drug is free from hazard. Do not use during pregnancy, especially during the first and last trimesters unless there are compelling reasons.

Adverse effects: Common adverse effects of benzodiazepines include drowsiness, sedation, blurring of vision, unsteadiness and ataxia. These symptoms are liable to be potentiated by alcohol. The elderly are more liable to experience such effects. (See also under Dependence Potential and Withdrawal Symptoms).

Abnormal psychological reactions to benzodiazepines have been reported. Rare behavioural adverse effects include paradoxical aggressive outbursts, excitement, confusion and the uncovering of depression with suicidal tendencies.

Other rare adverse effects, including hypotension, gastro-intestinal and visual disturbances, skin rashes, urinary retention, headache, vertigo, changes in libido, blood dyscrasias and jaundice have been reported.

Precautions: Give with caution to patients with chronic pulmonary insufficiency, or renal or hepatic dysfunction. Avoid benzodiazepines if possible during lactation.

The concurrent use of other CNS depressant drugs should be avoided.

Dependence potential and withdrawal symptoms: In general, the dependence potential of benzodiazepines is low, but this increases when high dosage is used, especially when given over long periods. This is particularly so in patients with a history of alcoholism, drug abuse or in patients with marked personality disorders. Regular monitoring of treatment in such patients is essential and routine repeat prescriptions should be avoided.

Treatment in all patients should be withdrawn gradually as symptoms such as depression, nervousness, rebound insomnia, irritability, sweating and diarrhoea have been reported following abrupt cessation of treatment with benzodiazepines in patients receiving even normal therapeutic doses for short periods of time.

Abrupt withdrawal following excessive dosage may produce confusion, toxic psychosis, convulsions or a condition resembling delirium tremens.

Overdosage: Doses substantially in excess of those recommended, have been taken without ill effect. As with other benzodiazepines, treatment of overdosage should be symptomatic with general supportive measures as required. Although temazepam in this formulation is rapidly absorbed, gastric lavage may be useful if performed shortly after ingestion.

Pharmaceutical precautions Dispense in glass or plastic containers.

Legal category POM.

Package quantities Containers of 50, 100, 500 or 1,000 capsules.

Further information The formulation of temazepam as a solution in soft gelatin capsules ensures rapid and complete absorption which, with its short half-life and

lack of active metabolites, results in prompt induction of sleep and a low incidence of hangover effects.

Temazepam is a short-acting benzodiazepine. As accumulation tends not to occur, patients are less likely to experience excessive drowsiness or impairment in the performance of skilled tasks. The short half-life of this drug may offer advantages in the treatment of the elderly, in patients with impaired renal or liver function, and in situations where day-time alertness is desirable.

Product licence number 3433/0024.

EUHYPNOS[®] FORTE

Presentation Green soft gelatin capsules, marked '20' in white, containing temazepam 20 mg in solution.

Uses Euhypnos Forte is indicated for the short-term treatment of sleep disturbances, particularly where lower doses of temazepam are not sufficient.

Euhypnos Forte is also indicated for pre-medication in minor surgical or investigatory procedures, especially in the case of out-patients.

Dosage and administration *Insomnia – Adults:* For those patients resistant to a low hypnotic dosage, two or three capsules before retiring.

Elderly: Half the normal adult dose may be sufficient for a therapeutic response in the elderly (see Warnings and Adverse Effects).

Children: Not recommended.

Pre-medication: 1 to 2 capsules from half to one hour prior to surgical or investigatory procedures.

Contra-indications, warnings, etc *Contra-indications:* Known sensitivity to benzodiazepines. Acute pulmonary insufficiency.

Warnings: Although hangover effect is uncommon, patients should be warned against driving or operating dangerous machinery if so affected.

Doses of 30 mg and above of temazepam are more likely to cause hangover effects to persist into the following day than lower doses, particularly in patients unused to hypnotics and in the elderly.

As with all compounds which have an effect on the CNS, patients should be advised not to consume alcohol whilst taking Euhypnos Forte.

Use in pregnancy: There is no evidence as to drug safety in human pregnancy nor is there evidence from animal work that the drug is free from hazard. Do not use during pregnancy especially during the first and last trimesters unless there are compelling reasons.

Adverse effects: Common adverse effects of benzodiazepines include drowsiness, sedation, blurring of vision, unsteadiness and ataxia. These symptoms are liable to be potentiated by alcohol. The elderly are more liable to experience such effects. (See also under Dependence Potential and Withdrawal Symptoms).

Abnormal psychological reactions to benzodiazepines have been reported. Rare behavioural adverse effects include paradoxical aggressive outbursts, excitement, confusion and the uncovering of depression with suicidal tendencies.

Other rare adverse effects, including hypotension, gastro-intestinal and visual disturbances, skin rashes, urinary retention, headache, vertigo, changes in libido, blood dyscrasias and jaundice have been reported.

Precautions: Give with caution to patients with chronic pulmonary insufficiency, or renal or hepatic dysfunction.

Avoid benzodiazepines if possible during lactation. The concurrent use of other CNS depressant drugs should be avoided.

Dependence potential and withdrawal symptoms: In general the dependence potential of benzodiazepines is low, but this increases when high dosage is used, especially when given over long periods. This is particularly so in patients with a history of alcoholism, drug abuse or in patients with marked personality disorders. Regular monitoring of treatment in such patients is essential and routine repeat prescriptions should be avoided.

Treatment in all patients should be withdrawn gradually as symptoms such as depression, nervousness, rebound insomnia, irritability, sweating and diarrhoea have been reported following abrupt cessation of treatment with benzodiazepines in patients receiving even normal therapeutic doses for short periods of time.

Abrupt withdrawal following excessive dosage may produce confusion, toxic psychosis, convulsions or a condition resembling delirium tremens.

Overdosage: Doses substantially in excess of those recommended, have been taken without ill effect. As with other benzodiazepines, treatment of overdosage should be symptomatic with general supportive measures as required. Although temazepam in this formulation is rapidly absorbed, gastric lavage may be useful if performed shortly after ingestion.

Pharmaceutical precautions Dispense in glass or plastic containers.

Legal category POM.

Package quantities Containers of 50, 250 or 500 capsules.

Temazepam is a short-acting benzodiazepine. As accumulation tends not to occur, patients are less likely to experience excessive drowsiness or impairment in the performance of skilled tasks. The short half-life of this drug may offer advantages in the treatment of the elderly, in patients with impaired renal or liver function and in situations where day-time alertness is desirable.

Product licence number 3433/0041.

EUHYPNOS[®] ELIXIR

Presentation A clear, green, lemon-mint flavoured elixir containing 10 mg temazepam per 5 ml.

Uses Euhypnos Elixir is indicated for the short-term treatment of sleep disturbances particularly where a liquid formulation is preferable.

Euhypnos Elixir is particularly suitable for patients with transient sleep disorders in whom the re-establishment of normal sleep patterns is expected following the resolution of precipitating factors.

Euhypnos Elixir is also indicated for pre-medication for minor surgery and investigatory procedures, especially in out-patients.

Dosage and administration

Insomnia: Adults: Each 5 ml spoonful of Euhypnos Elixir is equivalent to 10 mg temazepam.

The usual dose is 5 to 15 ml orally on retiring; a dose of 10 ml will be found satisfactory for most patients and is equivalent to 20 mg temazepam in capsule form.

This may be increased to 20 or 30 ml (40–60 mg emazepam) in patients who do not respond to the lower dose.

Elderly: Half the normal dose may be sufficient for a herapeutic response in the elderly (see Warnings and dverse Effects).

Children: Not recommended.

Pre-medication: 10 to 20 ml from half an hour to one our prior to surgery or investigatory procedures.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to benzodiazepines. Acute pulmonary insufficiency.

Warnings: Although hangover effect is uncommon, atients should be warned against driving or operating langerous machinery if so affected.

Doses of 15 ml and above are more likely to cause angover effects to persist into the following day than ver doses, particularly in patients unused to hypnotics nd in the elderly. As with all compounds which have an ffect on the CNS, patients should be advised not to onsume alcohol whilst taking Euhypnos Elixir.

Use in pregnancy: There is no evidence as to drug safety n human pregnancy, nor is there evidence from animal ork that the drug is free from hazard. Do not use during regnancy, especially during the first and last trimesters, nless there are compelling reasons.

Adverse effects: Common adverse effects of benzodiazepines include drowsiness, sedation, blurring of vision, nsteadiness and ataxia. These symptoms are liable to e potentiated by alcohol. The elderly are more liable to xperience such effects. (See also under Dependence 'ontential and Withdrawal Symptoms). Abnormal psy- chological reactions to benzodiazepines have been ported. Rare behavioural adverse effects include aradoxical aggressive outbursts, excitement, confusion nd the uncovering of depression with suicidal endencies.

Other rare adverse effects, including hypotension, astro-intestinal and visual disturbances, skin rashes, rinary retention, headache, vertigo, changes in libido, lood dyscrasias and jaundice have been reported.

Precautions: Give with caution to patients with chronic ulmonary insufficiency, or renal or hepatic dysfunction. void benzodiazepines if possible during lactation. The oncurrent use of other CNS depressant drugs should be voided.

Dependence potential and withdrawal symptoms: In eneral, the dependence potential of benzodiazepines is w, but this increases at high dosage, especially over ng periods. This is particularly so in patients with a istory of alcoholism or drug abuse or in patients with arked personality disorders. Regular monitoring of eatment in such patients is essential and routine repeat rescriptions should be avoided.

Treatment in all patients should be withdrawn gradu- ally as symptoms such as depression, nervousness, ound insomnia, irritability, sweating and diarrhoea ave been reported following abrupt cessation of eatment with benzodiazepines in patients receiving ven normal therapeutic doses for short periods of time.

Abrupt withdrawal following excessive dosage may roduce confusion, toxic psychosis, convulsions or a ondition resembling delirium tremens.

Overdosage: Doses of temazepam substantially in excess of those recommended have been taken without ill effect. As with other benzodiazepines, treatment of overdosage should be symptomatic with general sup- portive measures as required. Although temazepam in this formulation is rapidly absorbed, gastric lavage may be useful if performed shortly after ingestion.

Pharmaceutical precautions Store below 25°C and protect from direct light.

Legal category POM.

Package quantities Bottles of 300 ml and 2 litres.

Further information The formulation of temazepam as an elixir ensures rapid and complete absorption which, with its short half-life and lack of active metabolites, results in prompt induction of sleep and a low incidence of hangover effects.

Temazepam is a short-acting benzodiazepine. As accumulation tends not to occur, patients are less likely to experience excessive drowsiness or impairment in the performance of skilled tasks. The short half-life of this drug may offer advantages in the treatment of the elderly, in patients with impaired renal or liver function, and in situations where daytime alertness is desirable.

Product licence number 3433/0054.

FARLUTAL®

Presentation White, sterile suspension for i.m. injection, which settles on standing and readily disperses on shaking, containing 500 mg of medroxyprogesterone acetate in 2.5 ml or 1,000 mg in 5.0 ml.

Uses Palliative treatment of hormone-dependent malignancies. Farlital has been successfully used to produce regressions in breast, endometrial, prostatic and renal cell carcinoma. High dose Farlital therapy has proved especially useful for breast carcinoma and in achieving subjective improvements in terminally ill patients, notably pain relief and improved performance status.

Farlital may be used in combination with cytotoxic drugs.

Dosage and administration Suggested dosage schemes are as follows:

Breast carcinoma:

Initial dose 500–1,000 mg/day i.m. for 4 weeks.
Maintenance 500 mg i.m. twice a week.

Endometrial carcinoma:

Initial dose 500 mg i.m. twice weekly for 3 months.
Maintenance 500 mg i.m. weekly.

Renal adenocarcinoma:

Initial dose 500 mg i.m. on alternate days for 30 days.
Maintenance 500 mg i.m. twice weekly until 60th day then 250 mg i.m. weekly.

Prostatic carcinoma:

Initial dose 500 mg i.m. twice weekly.
Maintenance 500 mg i.m. weekly.

Administration should be by deep injection into alternate gluteal muscles using a long wide-bore needle such as 21 G × 1½ (8/10 40 mm). Narrow-bore or short needles must not be used.

Contra-indications, warnings, etc

Contra-indications: Thrombophlebitis, thrombo-embolic disorders, severe hepatic insufficiency and hypercalcaemia as may occur in patients with osseous metastases; also, suspected or early breast carcinoma, missed abortion, metrorrhagia, pregnancy and known hypersensitivity to hydroxybenzoates (excipients) and/or medroxyprogesterone acetate.

Warnings: Farlutal should be used under the direction of those experienced in cancer chemotherapy.

Since medroxyprogesterone acetate appears to enhance blood clotting potential, treatment should be discontinued upon the appearance of thrombo-embolic episodes, migraine or associated ocular problems such as sudden partial or total loss of vision, diplopia or vascular lesions of the retina.

In the event of vaginal bleeding occurring, an accurate diagnosis should be made. If a histological examination is indicated, the laboratory should be informed that the patient has been receiving a progestogen.

Precautions: Animal studies have shown that medroxyprogesterone acetate possesses adrenocorticoid activity and this effect has also been observed in humans. Patients treated with high doses continuously over long periods should be carefully observed for signs normally associated with adrenocorticoid therapy, such as hypertension, sodium retention, oedema, etc, and care is needed in treating patients with diabetes and/or arterial hypertension.

Farlutal may raise plasma calcium levels; some cases of hypercalcaemia have been reported in the treatment of breast carcinoma.

Administration of progesterone during the first months of pregnancy may possibly be associated with the occurrence of congenital cardiac malformations in the neonate. In addition, instances of masculinisation of female foetuses have been reported following high dose therapy during pregnancy. For these reasons, Farlutal is contra-indicated during pregnancy.

It should be noted that long term administration of medroxyprogesterone acetate to beagle dogs has resulted in the development of mammary nodules which were occasionally found to be malignant. The relevance of these findings to humans has, however, not been established.

Side effects: As is generally found after intramuscular administration of large volumes of suspension, this preparation may cause local lesions at the injection site, such as sterile abscesses or inflammatory infiltrates. The suspension should, therefore, be well shaken before use and injected deeply into healthy gluteal muscle.

In common with other progestogens, Farlutal may cause mastodynia, galactorrhoea, vaginal bleeding, changes in menstrual flow, amenorrhoea, cervical erosions and modifications of cervical secretions. Farlutal also exerts a corticoid-like effect which may lead to facies lunaris, Cushingoid syndrome and weight changes; and an adrenergic-like action which may result in fine hand tremors, sweating and cramps in the calves at night. Cholestatic jaundice has occasionally been reported.

Pharmaceutical precautions Farlutal should be well shaken before use and should not be mixed with other agents. The vials are for single dose administration only. Farlutal should be stored between 15°–30°C and should not be frozen.

Package quantities 500 mg and 1,000 mg vials supplied in individual cartons.

Legal category POM.

Further information Analysis of the various dosage schedules so far employed indicates that higher response rates may be obtained by rapid attainment and maintenance of high plasma levels. The intramuscular injection of Farlutal as a 20% suspension of medroxyprogesterone acetate, enables these levels to be achieved while minimising the local side effects associated with high dose therapy using formulations of lower concentrations.

Product licence number 3433/0045.

FLOSINT* ▼

Presentation White, uncoated, biconvex, scored tablets containing 200 mg indoprofen.

Uses Flosint is an analgesic anti-inflammatory indicated for the treatment of the arthritides: rheumatoid arthritis, osteo-arthritis, ankylosing spondylitis and others. Its analgesic activity may be utilised in a variety of disorders characterised by mild to moderate pain such as lower limb ischaemia, episiotomy and other surgical and dental procedures, and malignancy.

Dosage and administration *Adults:* The recommended initial dosage of indoprofen is 200–600 mg daily in two to three divided doses. In some severe conditions it can be advantageous to increase the daily dosage to 800 mg. Maintenance therapy can be accomplished by reducing the dosage to the level which gives satisfactory relief of symptoms for prolonged periods. The tablets should be taken after food to increase tolerability.

Children: Paediatric usage has not been established.

Contra-indications, warnings, etc

Contra-indications: Indoprofen is a propionic acid derivative and a prostaglandin synthetase inhibitor. It should not be given to patients with known sensitivity to this class of compounds or to patients with active peptic ulceration.

Warnings: Bronchospasm may be precipitated in patients suffering from or with a previous history of bronchial asthma or allergic disease. Indoprofen is extensively protein-bound, and may displace oral anti-coagulants, sulphonylureas, etc. from binding sites. Dosage alterations may be needed in patients requiring concomitant treatment with these agents.

Dosage reduction may be required in renal or hepatic impairment.

Pregnancy: Animal experiments show no evidence of teratogenicity. However, this class of compounds has been shown to delay parturition in animals. The use of indoprofen during pregnancy should be avoided if possible.

Adverse effects: The most common adverse reaction caused by indoprofen are gastro-intestinal, including dyspepsia and nausea. Haemorrhage can occur rarely as well as exacerbation of latent peptic ulceration. Other effects include mild central nervous system symptoms such as dizziness and headache, and also skin rashes of various types. Decrease in platelet count has been observed rarely and blood dyscrasias may uncommonly occur. Limited data available suggests that abnormal liver function may be further impaired by treatment with indoprofen.

Overdosage: Gastric lavage and general supportive treatment should be carried out. There is no specific antidote.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Containers of 100 tablets.

Further information Nil.

Product licence number 3433/0034.

KELFIZINE* W

Presentation White, uncoated tablets each containing sulfametopyrazine 2 g stamped 'Kelfizine W' on one face, and 'Weekly Dose' on obverse.

Ivory-coloured suspension in syrup base, containing sulfametopyrazine 500 mg in each 5 ml.

Uses The treatment of infections due to sulphonamide sensitive organisms. It has been used in the management of: chronic bronchitis (including prophylaxis); urinary tract infections; ear, nose and throat infections; bacillary dysentery; meningitis.

Dosage and administration

Adults: 2 g once weekly by mouth.

Children: 30 mg/kg once weekly by mouth.

The tablet should be stirred into half-a-tumblerful of water or orange squash.

Contra-indications, warnings, etc

Contra-indications: Not to be taken by persons sensitive to sulphonamides. The use of Kelfizine W is not recommended for infants under one year of age; it is, therefore, also not recommended for use in breast-feeding mothers. Sulfametopyrazine should be used with caution in patients with renal or hepatic dysfunction, dehydration, or blood dyscrasias. Sulphonamides should not be used during the last few weeks of pregnancy unless considered essential by the physician.

Overdosage: Doses up to 8 g have been taken over 36 hours without evidence of ill effects. A high fluid intake should be maintained for seven days and the urine rendered alkaline with Potassium Citrate mixture or Sodium Bicarbonate.

Pharmaceutical precautions The suspension may be diluted with Syrup BP if required.

Legal category POM.

Package quantities

Tablets: Pack of 5, individually foil wrapped.

Suspension: Paediatric single dose 10 ml bottle.

Adult single dose 20 ml bottle.

Further information The long half-life of sulfametopyrazine is due not to a high degree of serum protein binding (which is only 60%) but to a high degree of renal tubular re-absorption coupled with a low rate of hepatic metabolism of the drug. Accordingly, if it is required to accelerate elimination of the drug, this may be accomplished by rendering the urine alkaline (approximately pH 8) by means of Potassium Citrate Mixture BPC or other suitable agent. The sulphonamide will then be retained in the urine in higher concentrations in the form of the alkali metal salt.

Tablets 3433/5916

Suspension 3433/0027

KEMICETINE* SUCCINATE KEMICETINE* STERILE SURGICAL POWDER

Presentation

Kemicetine Succinate: Individual glass vials of chloramphenicol sodium succinate for injection containing the equivalent of 1 g of chloramphenicol.

Kemicetine Sterile Surgical Powder: Single glass vials with rubber caps in individual blister packs containing 1 g of sterile, pyrogen-free chloramphenicol.

Uses Kemicetine (chloramphenicol) is a broad-spectrum antibiotic and is active against many gram-positive and gram-negative organisms, spirillae and rickettsia. Kemicetine should not be used for trivial infections due to the possibility of severe blood dyscrasias, which may prove fatal.

Kemicetine succinate is indicated for typhoid, paratyphoid, meningitis caused by *H. influenzae* infections and other serious infections. It is also indicated wherever chloramphenicol is deemed the antibiotic of choice and oral administration is not possible, or higher than usual blood concentrations are required.

Kemicetine sterile surgical powder is applied locally before wound closure in general and especially after orthopaedic surgery, to assist in the prevention of infection.

Dosage and administration

Kemicetine Succinate: In order to ensure rapid attainment of high blood levels, Kemicetine Succinate is best administered by i.v. injection. Where this is not possible, however, intramuscular administration may be used, although it should be borne in mind that absorption may be slow and unpredictable.

The injection should be reconstituted with Water for Injections, Sodium Chloride Injection, or Dextrose Injection 5%. The following dilution table may be useful for the administration of a proportion of the contents of a vial:

Concentration	Solution strength	Volume of diluent to be added	Total volume after dilution
40%	400 mg/ml	1.7 ml	2.5 ml
25%	250 mg/ml	3.2 ml	4.0 ml
20%	200 mg/ml	4.2 ml	5.0 ml
10%	100 mg/ml	9.2 ml	10.0 ml

The dose administered and the concentration used is dependent on the severity of the infection. The recommended standard dosage is as follows:

Adults: The equivalent of 1 g chloramphenicol every 6–8 hours.

Children: The equivalent of 50 mg/kg chloramphenicol, according to body weight, daily in divided doses every 6 hours (this dose should not be exceeded). The patient should be carefully observed for signs of toxicity.

Neonates and premature infants: 25 mg/kg in divided doses.

Certain infections, such as meningitis or septicaemia, may require substantially higher doses.

The 10% solution should be given by intravenous injection over a period of about a minute, or in a larger volume of fluid, by slow intravenous infusion.

Kemicetine succinate has been applied locally in cases of acute peritonitis, perforated appendix and similar

states where doses of 10–20 ml of 10% solution were introduced into the peritoneal cavity during the operation, or during the following days, through drainage tubes. The concurrent administration of i.v. Kemicetine with topical treatment, has been found to be very effective in the treatment of osteomyelitic foci, abscesses, empyema and skin and urinary infections.

Kemicetine Sterile Surgical Powder: At the conclusion of surgery, particularly orthopaedic procedures, 1 g may be sprinkled into the wound before closure.

Contra-indications, warnings, etc Kemicetine is to be administered only under the direction of a medical practitioner. Chloramphenicol may cause severe bone marrow depression which may lead to agranulocytosis, thrombocytopenic purpura or aplastic anaemia. These effects on the haemopoietic system are usually associated with a high dose, prolonged administration, or repeated courses, but they may occur at relatively low doses. Chloramphenicol should not, therefore, be used in the treatment of any infection for which a less toxic antibiotic is available. It is also advisable to perform blood tests in the case of prolonged or repeated administration. Evidence of any detrimental effect on blood elements is an indication to discontinue therapy immediately.

Other adverse reactions which may become apparent after chloramphenicol treatment are: dryness of the mouth, nausea and vomiting, diarrhoea, urticaria, optic neuritis and blurring, or temporary loss of vision. Superinfection by fungi, e.g. *C. albicans* in the gastrointestinal tract, or vagina, may also occur due to the disturbance of normal bacterial flora.

Chloramphenicol has been shown to interact with, and enhance the effects of, coumarin anticoagulants, some hypoglycaemic agents (e.g. tolbutamide) and phenytoin. When given concurrently, a dose reduction of these agents may, therefore, be necessary. Chloramphenicol may also impede the development of immunity and should therefore not be given during active immunisation.

The drug should be used with great caution in patients with impairment of hepatic or renal function. 'The Grey Syndrome' may occur after administration, in patients with immature hepatic metabolic capacity, i.e. infants and neonates, usually in those treated with doses substantially in excess of those recommended.

Pharmaceutical precautions Any Kemicetine succinate solution remaining in the vial after use should be discarded, as chloramphenicol sodium succinate is not bactericidal or bacteriostatic.

Kemicetine Succinate	3433/5903

LEVIUS*

Presentation Uncoated, controlled-release tablets

each containing aspirin 500 mg microencapsulated with ethylcellulose.

Uses Analgesic, anti-inflammatory and antipyretic. For use as an alternative to Aspirin Tablets BP, particularly in chronic painful conditions such as rheumatoid arthritis, osteoarthritis, and chronic rheumatic conditions where prolonged treatment may be needed. This, however, does not diminish its suitability for the short-term treatment of, for example, feverish colds, influenza, sprains, lumbago and the relief of mild to moderate pain including headache, toothache and dysmenorrhoea.

Dosage and administration *Standard Dose:* One or two tablets every four hours or as prescribed by the physician. Maximum daily dose should generally not exceed 4 g except in the treatment of acute rheumatism for which 4–8 g in divided doses is recommended.

Children (up to the age of 12): One tablet every four hours or as prescribed by the physician. The daily dose should generally not exceed 80 mg/kg.

Contra-indications, warnings, etc

Contra-indications: Active peptic ulceration, haemophilia and hypersensitivity to aspirin or salicylates.

Precautions: Aspirin may prolong labour and contribute to maternal and neonatal bleeding, and is best avoided at term. There is clinical evidence of safety in human pregnancy. Aspirin may enhance the effect of anticoagulants and inhibit the action of uricosurics. It may precipitate bronchospasm or induce attacks of asthma in susceptible subjects.

Warnings and adverse effects: Levius may induce 'aspirin-type' hypersensitivity, asthma or gastrointestinal haemorrhage which may occasionally be severe.

Overdosage: The fatal dose varies, 10–30 g have caused death but much larger doses have been ingested without fatal outcome. The symptoms of overdosage include headache, epigastric pain, dizziness, tinnitus, sweating, nausea, vomiting, confusion and hyperventilation. More serious signs of toxicity include fever, ketosis, respiratory alkalosis and metabolic acidosis. Depression of the CNS may lead to coma, cardiovascular collapse and respiratory failure. Treatment is largely symptomatic and the patient should be hospitalised. Absorption from the G.I. tract may be reduced by emesis, gastric lavage and/or administration of activated charcoal. In severe poisoning, extra-renal measures such as exchange transfusion, peritoneal dialysis, haemodialysis and haemoperfusion are the most effective measures available for the removal of salicylate, while electrolyte imbalance may need constant monitoring and i.v. infusion correction.

Pharmaceutical precautions Store in a cool dry place.

Legal category P.

Package quantities Amber, child-resistant containers of 30 tablets and Securitainers of 500 tablets.

Further information Aspirin is released from the microcapsules by a process of dialysis over a period of about one hour. As this process is steady and progressive, no part of the alimentary tract receives the full irritant effect of all the aspirin contained in the tablet. Moreover, the analgesia resulting from the aspirin is more prolonged than from a conventional tablet.

Product licence number 3433/0018.

MINODIAB*

Presentation Minodiab is available as white, biconvex, scored 8 mm tablets containing 5 mg of glipizide.

Uses Minodiab is an orally active hypoglycaemic sulphonylurea and has been shown to be effective in the treatment of maturity-onset diabetes. In certain patients receiving insulin, the concurrent use of Minodiab allows a reduction in the daily dose of insulin.

Dosage and administration The usual dose range of Minodiab is 2.5–20 mg daily; this may be increased to a daily total of 30 mg at the clinician's discretion although the additional proportion of patients responding to this higher dosage may not be large. The initial dose, in patients previously untreated with oral hypoglycaemic agents is 2.5–5 mg daily. The dose, thereafter, can be adjusted to obtain the optimum effect.

Doses of up to 5 mg may be taken as a single dose with the main meal or in two divided doses with morning and evening meals. Doses of 7.5 mg or more may be taken in three divided doses with meals. The use of multiple divided doses is intended to produce more even control of post-prandial blood glucose peaks throughout the day. The dose must be adjusted according to the patient's response; the daily dose to be increased, or decreased by 2.5 or 5 mg every three to five days until the desired control is achieved.

When Minodiab replaces other oral antidiabetic agents, the recommended starting dose is 5 mg daily in a divided dose. If the dose given is considered adequate but the control is not, a biguanide may be added.

Contra-indications, warnings, etc

Contra-indications: Minodiab is contra-indicated in pregnancy, juvenile diabetes, diabetic ketoacidosis, diabetic coma, severe renal or hepatic insufficiency, infections and febrile conditions, gangrene and in severe trauma and major surgical procedures.

Warnings: Concurrent use of MAOIs, phenylbutazone, β -blockers, sulphonamides, coumarin derivatives or salicylates may enhance the hypoglycaemic effect. Conversely the effect may be diminished in the presence of adrenaline, corticosteroids, oral contraceptives and thiazide diuretics.

Patients should be instructed to take their meals regularly and not to exercise excessively without additional calorie intake. Failure to do so may result in a hypoglycaemic episode. The hypoglycaemia is controlled by giving carbohydrates.

Adverse reactions: Side-effects are not common with Minodiab. Those that do occur are associated with the gastro-intestinal tract, and include nausea, vomiting, anorexia, gastric pain, etc. Skin reactions have been reported, e.g. rash, urticaria, pruritus, etc. Other reactions include headache, dizziness and vertigo.

Overdosage: Gastric lavage should be performed as soon as possible. Hypoglycaemia should be treated as it occurs with appropriate measures including oral or i.v. glucose.

Pharmaceutical precautions None.

Legal category POM.

Package quantities *Minodiab 5 mg Tablets:* Bottles of 100 tablets and tins of 1,000 tablets.

Further information Glipizide can be considered to have a physiological action as its peak effect coincides with post-prandial peak blood-sugar levels. It is rapidly

absorbed from the gastro-intestinal tract; the absorption being practically complete. Peak concentrations are achieved in the blood within 60 minutes and the half-life is approximately three and a half hours. The excretion of glipizide and its metabolites, which are inactive, occurs mainly in the urine. During the first 24 hours, about 80–85% of the ingested drug is excreted in the urine and about 10% in the faeces. These properties make Minodiab particularly suitable for the treatment of maturity-onset diabetes. Taken with a meal, therapeutic effects are seen within 30 minutes and reach a peak at about 60 minutes. The rapid metabolism and excretion makes it unlikely that delayed hypoglycaemic episodes will occur.

Product licence number 3433/0023.

NAXOGIN* 500

Presentation Naxogin 500 is available as white or slightly yellow bi-convex tablets scored on one side and plain on the other. Each tablet contains 500 mg nimorazole.

Uses Naxogin is a trichomonocidal agent. It is indicated for the systemic treatment of trichomonal vaginitis. Sexual partners should also be treated even if they are free of symptoms.

Naxogin is also effective against other protozoa and thus may be used for the treatment of giardiasis, amoebiasis, and acute ulcerative gingivitis.

Dosage and administration *For the treatment of trichomoniasis:* 2 g (4 tablets) to be taken together as a single dose with a main meal. This may be repeated if there is no clinical improvement.

For acute ulcerative gingivitis: 500 mg twice daily for two days.

For giardiasis or amoebiasis: Adults: 500 mg twice daily for five days.

Children (over 10 kg body weight): 500 mg daily for five days.

Children (under 10 kg body weight): 250 mg daily for five days.

Contra-indications, warnings, etc Like all nitroimidazoles, Naxogin 500 is contra-indicated for nursing mothers as it is excreted in breast milk and the effect on the neonate is unknown. Also this group of drugs should not be given in the presence of active CNS disease. Treatment should be discontinued if ataxia or other CNS symptoms appear.

Naxogin 500 should be given with caution during pregnancy although there is no known teratogenicity. Clinical studies have been carried out during pregnancy and no untoward effects of any kind have been associated with this drug. As Naxogin 500 is excreted principally via the kidneys, overt renal insufficiency is also a contra-indication.

Unwanted effects are rare and may comprise transient gastro-intestinal effects such as nausea and vomiting. No blood dyscrasias have been reported. Intolerance to alcohol, similar to that induced by disulfiram, has been observed with the nitroimidazoles but is rarely troublesome with nimorazole.

Overdosage: There is no specific treatment but gastric lavage should be performed as soon as possible. Supportive measures should be instituted as required and a high fluid intake maintained.

Pharmaceutical precautions None.

Legal category P.

Package quantities *Tablets 500 mg:* Bottles of 8 and 100 tablets.

Further information Naxogin 500 is well absorbed after oral administration, achieving blood levels of 32 mcg/ml within two hours and 1.9 mcg/ml at 24 hours. The metabolites of the drug are trichomonacidal and are excreted mainly by the kidney so that there are high urinary concentrations. Concentrations are high in vaginal and salivary secretions.

Naxogin 500 is also recommended for the treatment of acute ulcerative gingivitis in patients hypersensitive to penicillin.

Product licence number 3433/5914.

PHARMIDONE*

Presentation Yellow, scored, tablets each containing:

Codeine Phosphate Ph Eur	10 mg
Diphenhydramine Hydrochloride BP	5 mg
Paracetamol Ph Eur	400 mg
Caffeine Ph Eur	50 mg

Uses Analgesic, in the treatment of headache, migraine, muscular pain and nerve pain.

Dosage and administration *For adults and children over 12 years of age:* One or two tablets orally every four hours, up to a maximum of ten tablets in 24 hours.

Contra-indications, warnings, etc Pharmidone may cause drowsiness, and if affected, the patient should not drive or operate machinery. The effect of alcohol and other sedatives may be potentiated.

Pharmidone should not be given to patients with known liver or renal impairment.

Pharmidone should not be administered to children.

Safety in pregnancy has not been established.

Overdosage: The effects of overdosage are predominantly those of paracetamol; vomiting, gastrointestinal haemorrhage, liver damage, cerebral oedema, and renal tubular necrosis may occur. Gastric lavage should be carried out and haemodialysis may be necessary if renal failure occurs.

Pharmaceutical precautions None.

Legal category P.

Package quantities Boxes of 12 and containers of 100 tablets.

Further information Nil.

Product licence number 3433/0042.

SINTISONE*

Presentation White, scored tablets each containing 6.65 mg of prednisolone teaglate, therapeutically equivalent to prednisolone 5 mg.

Uses Sintisone is a synthetic glucocorticoid and is indicated in all conditions that respond to corticosteroid treatment, such as: rheumatoid arthritis, rheumatic fever, asthma, ulcerative colitis, pemphigus, sarcoidosis, systemic lupus erythematosus, nephrotic syndrome, scleritis, skin conditions and polyarteritis nodosa.

Sintisone may also be used in cancer chemotherapy when a corticosteroid is indicated.

Dosage and administration *Adults:* The average initial dose for adults is 2–4 tablets, orally, twice daily, gradually reducing this to a maintenance dose of 1–3 tablets daily.

Children: Initial dose: 0.6–2 mg/kg body weight, orally in divided doses. Maintenance dose: 1 mg/kg body weight, orally in divided doses.

Treatment may be given in short (6–10 day) courses for the alleviation of the symptoms of acute inflammatory episodes.

Alternate-day corticosteroid therapy is known to reduce the incidence of unwanted effects. Sintisone may be used with advantage in this manner by giving twice the normal daily dose every other day.

Treatment with corticosteroids should not terminate abruptly but should be withdrawn gradually.

Contra-indications, warnings, etc The contra-indications are those common to other corticosteroids: active tuberculosis, peptic ulcer, acute psychosis, Cushing's disease, osteoporosis, hypertension, diabetes mellitus and a tendency to thromboembolic episodes. Corticosteroids are usually also contra-indicated in the presence of acute bacterial or viral infections.

Patients receiving corticosteroids or who have been prescribed them during the preceding two years should be given supplementary corticosteroids for one to two days before surgery, and continued until stress has ceased before tapering off the dose.

Corticosteroids should be used with caution in pregnancy, especially during the first trimester.

Overdosage: There is no specific treatment but gastric lavage should be performed as soon as possible. Supportive measures should be instituted as required.

Pharmaceutical precautions Store in airtight containers and protect from light.

Legal category POM.

Package quantities Bottles of 100 tablets.

Further information Sintisone is a lipid soluble ester of prednisolone which is absorbed intact from the gut more completely than prednisolone. It circulates in the blood as the ester and is slowly metabolised to prednisolone. These properties confer on Sintisone a reduced tendency to the side-effects associated with corticosteroid therapy such as suppression of the pituitary/adrenal axis (Metrapone test), salt and water retention, calcium loss and raised intraocular pressure.

Product licence number 3433/5906.

TETRALYSAL* 300

Presentation Tetralysal 300 is available as white, hard gelatin capsules, size 'O', containing 408 mg of lymecycline BP, equivalent to 300 mg tetracycline base.

Uses Tetralysal 300 is recommended in the treatment of all infections caused by tetracycline-sensitive organisms and may be utilised in all conditions where tetracycline therapy is indicated. In common with other tetracyclines they are also indicated in penicillin-sensitive patients for the treatment of staphylococcal and streptococcal infections. As a prophylactic agent, they may be used in chronic bronchitis.

Dosage and administration Tetralysal 300 – The usual recommended dose is 1 capsule b.d. If higher

A small fraction of the active ingredients in oral contraceptives has been identified in the milk of mothers receiving these drugs. The effects, if any, on the breast-fed child have not been determined. If possible the use of oral contraceptives should be deferred until the infant is weaned.

Reduced efficacy and increased incidence of breakthrough bleeding have been associated with concomitant use of oral contraceptives and rifampicin. A similar association has been suggested with oral contraceptives and barbiturates, phenylbutazone, phenytoin sodium and ampicillin.

Reasons for stopping oral contraceptives immediately: Early manifestations of thrombotic or thromboembolic disorders, thrombophlebitis, cerebrovascular disorders (including haemorrhage), myocardial infarction, pulmonary embolism. Gradual or sudden, partial or complete loss of vision. Proptosis or diplopia. Onset or aggravation of migraine or development of headaches of a new pattern which are recurrent, persistent or severe. Papilloedema or any evidence of retinal vascular lesions. During periods of immobility (e.g. after accidents). Pregnancy. Manifestations of liver tumours.

Precautions: Examination of the pelvic organs, breasts and blood pressure should precede the prescribing of any oral contraceptive, and should be repeated regularly. The following are some of the medical conditions reported to be influenced by the combined pill, and may be affected by Micronor. The physician will have to exercise medical judgement to commence, continue or discontinue therapy as appropriate.

- a) Pre-existing uterine fibromyomata may increase in size.
- b) A decrease in glucose tolerance in a significant number of women.
- c) An increase in blood pressure in a small but significant number of women.
- d) Cholestatic jaundice. Patients with a history of cholestatic jaundice of pregnancy are more likely to develop cholestatic jaundice during oral contraceptive therapy.
- e) Amenorrhoea during and after oral contraceptive therapy. Women with a past history of oligomenorrhoea or secondary amenorrhoea or women with irregular cycles may be more likely to remain anovulatory or to become amenorrhoeic post oral contraceptive therapy.
- f) Depression.
- g) Fluid retention. Conditions which might be influenced by this factor include epilepsy, migraine, asthma, cardiac or renal dysfunction.
- h) Varicose veins.
- i) Multiple sclerosis.
- j) Porphyria.
- k) Tetany.
- l) Wearing of contact lenses.

or any condition that is prone to worsen during pregnancy.

The following laboratory determinations may be altered in patients using oral contraceptives.

Hepatic: Increased BSP retention and other tests.

Coagulation: Increased prothrombin, Factors VII, VIII, IX and X, decreased antithrombin III, increased platelet aggregability.

Endocrine: Increased PBI and butanol extractable protein bound iodine and decreased T³ uptake, increased glucose blood levels.

Other: Increased phospholipids and tri-glycerides, de-

creased serum folate values and disturbance in tryptophan metabolism, decreased pregnanediol excretion, reduced response to metyrapone test.

These tests usually return to pre-therapy values after discontinuing oral contraceptive use. However, the physician should be aware that these altered determinations may mask an underlying disease.

Side-effects: Micronor has been found to be a well tolerated drug. Side-effects are usually self-limiting and of relatively short duration. Amongst the symptoms reported are headaches, nausea, vomiting, breast changes, change in weight, chloasma, break-through bleeding and spotting. Particularly in the early cycles of therapy the menstrual pattern becomes irregular, some cycles being short and others long. It is important that patients should be advised that whilst on Micronor therapy they will experience that variation in cycle length.

Overdosage: Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea, and withdrawal bleeding may occur in females. An appropriate method of gastric emptying may be used if considered desirable.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Carton containing 3 pushpaks each of 28 tablets – sufficient for 3 cycles.

Further information Nil.

Product licence number 0076/0017.

MONISTAT* CREAM MONISTAT* PESSARIES

Presentation Cream: A white, water-miscible cream containing miconazole nitrate 2% w/w.

Pessaries: White egg-shaped pessaries each containing 100 mg miconazole nitrate and melting at 37°C.

Uses A potent antimycotic agent for the local treatment and rapid symptomatic relief of vulvovaginal moniliasis and balanitis.

Dosage and administration Cream: One applicatorful (approx. 5 g) intravaginally, with additional cream smeared onto other affected areas, once daily, preferably at night, for 14 days.

Pessaries: One pessary should be inserted high into the vagina at night for the same period.

Patients should be instructed not to discontinue treatment upon relief of symptoms, but to complete the prescribed course. The simultaneous treatment of the partner with Monistat Cream is advisable.

Contra-indications, warnings, etc Hypersensitivity to the product.

Side-effects: Isolated cases of vulvo-vaginal burning, itching and irritation have been reported after using the product. If this occurs administration of the product should be discontinued.

Overdosage: Monistat Cream and Pessaries are intended for intravaginal use. If accidental ingestion of large quantities of the product occurs, an appropriate method of gastric emptying may be used if considered desirable.

Pharmaceutical precautions Cream – none known.
Pessaries – store in a cool place.

Legal category POM.

Package quantities Cream: 78 g tube with ORTHO* Plastic Vaginal applicator.

Pessaries: Each pessary is completely sealed in PVC strips with seven pessaries to a strip. Each carton contains two strips of seven pessaries.

Both packs contain full patient instructions.

Further information Monistat Cream or Pessaries are particularly useful in the treatment of those patients with predisposing conditions for monilial vulvovaginitis – pregnancy, diabetes and those taking oral contraceptives or broad-spectrum antibiotics.

Cream 0076/0040

Pessaries 0076/0048

ORTHO-CREME* CONTRACEPTIVE CREAM

Presentation Ortho-Creme Contraceptive Cream is a white spermicidal cream which contains nonoxynol-9 2.0%.

Uses Ortho-Creme Contraceptive Cream is a spermicidal cream for the control of conception. A higher degree of protection against pregnancy will be afforded by using another method of contraception in addition to a spermicidal contraceptive.

Dosage and administration The cream should be spread over the surface of the diaphragm which will be in contact with the cervix, and on the rim. The diaphragm must be allowed to remain *in situ* for at least six to eight hours after coitus. A fresh application of cream or other spermicides, e.g. Orthoforms Contraceptive Pessaries, must be made prior to any subsequent act of coitus within this period of time, without removing the diaphragm. (A vaginal applicator should be used for inserting more cream or jelly.)

Contra-indications, warnings, etc Hypersensitivity to the product.

Warning: Where avoidance of pregnancy is essential, the choice of contraceptive should be made in consultation with a doctor or a family planning clinic.

Overdosage: Ortho-Creme Contraceptive Cream is intended for intravaginal use only, and if taken orally by mistake is likely to taste unpleasant. If excess quantities are swallowed, this may give rise to gastric irritation as the product contains a surfactant, and general supportive therapy should be carried out if necessary.

Pharmaceutical precautions None known.

Legal category GSL.

Package quantities Tubes containing 70 g.
ORTHO* Plastic Vaginal Applicator available separately.

Further information Nil.

Product licence number 0076/5008.

ORTHO* DIENOESTROL CREAM

Presentation A white non-staining cream containing 0.01% w/w dienioestrol.

Uses For intravaginal use only. Indicated in the treatment of atrophic vaginitis and kraurosis vulvae in postmenopausal women, and for the treatment of pruritis vulvae and dyspareunia when associated with the atrophic vaginal epithelium.

Dosage and administration Given for short term use only. The lowest dose that will control symptoms should be chosen and medication should be discontinued as promptly as possible.

Attempts to discontinue or taper medication should be made at three to six month intervals, following physical examination. The usual dosage range is one or two applicatorfuls per day for one or two weeks, then gradually reduced to one half initial dosage for a similar period. A maintenance dose of one applicatorful, one to three times a week, may be used after restoration of the vaginal mucosa has been achieved. Treated patients with an intact uterus should be monitored closely for signs of endometrial cancer and appropriate diagnostic measures should be taken to rule out malignancy in the event of persistent or recurring abnormal vaginal bleeding. As a general rule it is advisable that patients receiving any form of oestrogen replacement therapy should have a complete physical examination at least once a year.

Contra-indications, warnings, etc Prolonged exposure to unopposed oestrogen may increase the risk of development of endometrial carcinoma, induction of other malignant neoplasms, and the risk of cancer of the breast: long term continuous administration of natural and synthetic oestrogens in certain animal species increases the frequency of carcinomas of the breast, cervix, vagina and liver. There is now evidence that oestrogens increase the risk of carcinoma of the endometrium in humans.

At the present time there is no satisfactory evidence that oestrogens given to post-menopausal women increase the risk of cancer of the breast, although a recent long-term follow up of a single physician has raised this possibility. However, because of animal data there is a need for caution in prescribing oestrogens for women with a strong family history of breast cancer or who have breast nodules, fibrocystic disease, or abnormal mammograms.

Pregnancy is an absolute contra-indication to the use of Dienioestrol cream since it may be harmful to the developing foetus.

Oestrogens should not be used in women with any of the other following conditions: known or suspected cancer of the breast, known or suspected oestrogen-dependent neoplasia, undiagnosed abnormal genital bleeding, active thrombophlebitis or thromboembolic disorders, a past history of thrombophlebitis, thrombosis, or thromboembolic disorders.

Thromboembolic disorders: While an increased rate of thromboembolic and thrombotic disease in postmenopausal users of oestrogens has not been found, this does not rule out the possibility that such an increase may be present or that subgroups of women who have underlying risk factors or who are receiving relatively large doses of oestrogens may have increased risk. Therefore oestrogens should not be used in persons with active thrombophlebitis or thromboembolic disorders, and they should not be used (except in treatment of malignancy) in persons with a history of such disorders. They should be used with caution in patients with cerebral vascular or coronary artery disease and only for those in whom oestrogens are clearly needed.

Gall bladder disease: A recent study has reported a two to three-fold increase in the risk of surgically confirmed gall bladder disease in women receiving post-menopausal oestrogens, similar to the two-fold increase previously noted in users of oral contraceptives.

Hepatic adenoma: Benign hepatic adenomas appear to be associated with the use of oral contraceptives. Although benign, and rare, these may rupture and may cause death through intra-abdominal haemorrhage. Such lesions have not yet been reported in association with other oestrogen or progestogen preparations but should be considered in oestrogen users having abdominal pain and tenderness, abdominal mass, or hypovolemic shock.

Elevated blood pressure: It has been reported that this may occur with the use of oestrogens in the menopause and blood pressure should be monitored with oestrogen use, especially if high doses are used.

Precautions: A complete medical and family history should be taken prior to the initiation of any oestrogen therapy. The pretreatment and periodic physical examinations should include special reference to blood pressure, breasts, abdomen, and pelvic organs, and should include a Papanicolaou smear.

A pathologist should be advised of oestrogen therapy when relevant specimens are submitted.

Certain patients may develop undesirable manifestations of excessive oestrogenic stimulations, such as abnormal or excessive uterine bleeding, mastodynia, etc. Pre-existing uterine fibroids may increase in size during oestrogen use.

Patients with a past history of jaundice during pregnancy have an increased risk of recurrence of jaundice while receiving oestrogen therapy. If jaundice develops in any patient receiving oestrogen, the medication should be discontinued while the cause is investigated.

Oestrogens may aggravate cases of porphyria.

Overdosage: Ortho Dienoestrol Cream is intended for intravaginal use. If accidental ingestion of large quantities of the product occurs, an appropriate method of gastric emptying may be used if considered desirable.

Pharmaceutical precautions Store at room temperature.

Legal category POM.

Package quantities Tubes of 78 g with or without the ORTHO* Plastic Vaginal Applicator.

Further information Nil.

Product licence number 0076/5010.

ORTHOFORMS* CONTRACEPTIVE PESSARIES

Presentation White, opaque pessaries. Each pessary contains nonoxonyl-9 5% w/w.

Uses Whenever the control of conception is desired. Placed in the vagina, the pessary melts and rapidly forms a smooth emollient cream which spreads, mixing intimately with secretions and seminal fluid. Orthoforms Contraceptive Pessaries melt rapidly between 34°C and 37°C – the normal vaginal temperature range.

Orthoforms Contraceptive Pessaries are intended to add reliability to the use of other methods, such as the diaphragm, the sheath, the cervical cap, the IUCD, or

when intercourse is repeated without removing the appliance.

A higher degree of protection against pregnancy will be afforded by using another method of contraception in addition to a spermicidal contraceptive.

Dosage and administration The Orthoforms Contraceptive Pessary should be inserted as high as possible into the vagina approximately 5 minutes before intercourse to permit the pessary to melt. It retains its spermicidal activity for approximately 1 hour. Any subsequent acts of intercourse should not be undertaken before the insertion of an additional pessary.

Contra-indications, warnings, etc Hypersensitivity to the product.

Side-effects: Irritation of the vagina or penis has been reported. In such cases the medication should be discontinued.

Warnings: Where avoidance of pregnancy is essential the choice of contraceptive should be made in consultation with a doctor or a family planning clinic.

Overdosage: Orthoforms Contraceptive Pessaries are intended for intravaginal use only, and if taken orally by mistake are likely to taste unpleasant. If excess quantities are swallowed this may give rise to gastric irritation as the product contains a surfactant, and general supportive therapy should be carried out if necessary.

Pharmaceutical precautions Orthoforms Contraceptive Pessaries should be stored in a cool place.

Legal category GSL.

Package quantities Pack of 15 pessaries.

Further information Nil.

Product licence number 0076/5006.

ORTHO* GYNE-T* INTRAUTERINE COPPER CONTRACEPTIVE DEVICE

Presentation Each device consists of a polyethylene 'T' shaped support with 120 mg pure copper wire (providing a surface area of 200 sq. mm) wound around the vertical section of the 'T'.

The support is impregnated with a radiopaque substance and has a polyethylene suture attached to the base of the 'T'.

Uses Contraception.

Dosage and administration Ortho Gyne-T Intra-uterine Copper Contraceptive Device may be used in any woman of child-bearing age including nulligravidae patients.

One device is inserted by its introducer into the uterus. The device should be removed after three years of use. If continued contraception is required a new device should be inserted. The device should be placed as high as possible within the uterine cavity and the patient should check periodically, particularly after menstruation, to ensure that the threads still protrude from the cervix. She should return to her doctor if she becomes aware that the device has been expelled. When the threads cannot be felt by the patient and cannot be seen by her doctor further investigation is necessary.

Contra-indications, warnings, etc

Contra-indications: The use of the device is contraindicated in the following conditions:

1. Pregnancy or suspicion of pregnancy.
2. Abnormalities of the uterus resulting in distortion of the uterine cavity.
3. Pelvic inflammatory disease or a history of repeated pelvic inflammatory disease.
4. Post-partum endometritis or infected abortion in the past three months.
5. Known or suspected uterine or cervical malignancy including unresolved abnormal cervical smear.
6. Uterine bleeding of unknown aetiology.
7. Cervicitis until infection is controlled.
8. Known allergy to copper.

Warnings: The expulsion, perforation and removal rates may be increased when insertions are made before normal uterine involution occurs post partum.

The device should be removed for the following reasons:

1. Excessive and persistent bleeding or cramping.
2. Perforation of the uterus and location of the device outside the uterine cavity. In this case hospital investigation and surgical removal will be required.
3. Partial downward displacement of the device within the cervical canal.

Pregnancy: If a patient is found to be pregnant with an Ortho Gyne-T *in situ* and the thread is visible it is recommended that in the absence of reasons to the contrary the device be removed as soon as possible. As with other intrauterine devices the possibility exists that should a second trimester abortion occur sepsis may supervene, and hence the desirability of removing the device as early as possible. If the thread is not visible then it is recommended that the device is left *in situ* until the pregnancy goes to term or a decision is made to terminate the pregnancy.

Ectopic pregnancy: A pregnancy that occurs with an IUCD in place is more likely to be ectopic than a pregnancy that occurs without an IUCD in place. Accordingly patients who become pregnant while using an IUCD should be carefully evaluated for the possibility of ectopic pregnancy.

Pelvic infection: An increased risk of pelvic infection has been reported in women with IUCD's *in situ*.

Precautions: Prior to insertion of an IUCD a thorough history and physical examination, including a pelvic examination and Papanicolaou smear, should be performed. Insertion of an IUCD into a uterine cavity measuring less than 6.5 cm by sounding may increase the incidence of expulsion, bleeding, pain and perforation. The patient should be re-examined within three months after insertion and thereafter at yearly intervals to ensure the device is still in place. The patient should be advised to contact her doctor immediately if she misses a menstrual period or has any other reason to think she may be pregnant.

IUCDs should be used with caution in patients with anaemia, menorrhagia or hypermenorrhoea or in patients receiving anticoagulants or having any disorder of coagulation.

Syncope, bradycardia or other neuro-vascular episodes may occur during insertion or removal of IUCDs especially in patients susceptible to these conditions. Patients with known or suspected cardiac abnormalities should receive appropriate antibiotic cover during insertion of the device. No method of contraception is 100% effective. In some cases it may be appropriate to recommend the use of an additional reliable method of contraception at mid-cycle.

Overdosage: Not applicable.

Pharmaceutical precautions If the seal of the sterile pack is broken the device inside should not be used.

Legal category POM. Also available through family planning clinics.

Package quantities Each sterile Ortho Gyne-T Intra-uterine Copper Contraceptive Device unit is supplied in a sealed transparent envelope together with a sterile disposable GYNEPROBE* intrauterine sound for measuring the depth of the uterus. Full fitting instructions and advice for the patient are supplied with each device.

Further information Nil.

Product licence number 0076/0046.

ORTHO-GYNOL* CONTRACEPTIVE JELLY

Presentation Ortho-Gynol Contraceptive Jelly is a water-dispersible spermicidal jelly having a pH of 4.5, which contains *p*-diisobutylphenoxyethoxyethanol 1.0% w/w.

Uses Ortho-Gynol Contraceptive Jelly is a spermicidal jelly for use in conjunction with an occlusive vaginal diaphragm, whenever the control of conception is desirable.

A higher degree of protection against pregnancy will be afforded by using another method of contraception in addition to a spermicidal contraceptive.

Dosage and administration The jelly should be spread over the surface of the diaphragm which will be in contact with the cervix and on the rim. The diaphragm must be allowed to remain *in situ* for at least six to eight hours after coitus. A fresh application of jelly or other spermicides, e.g. Orthoforms Contraceptive Pessaries, must be made prior to any subsequent act of coitus within this period of time, without removing the diaphragm. (A vaginal applicator should be used for inserting more cream or jelly.)

Contra-indications, warnings, etc Hypersensitivity to the product.

Warning: Where avoidance of pregnancy is essential, the choice of contraceptive should be made in consultation with a doctor or family planning clinic.

Overdosage: Ortho-Gynol Contraceptive Jelly is intended for intravaginal use only, and if taken orally by mistake is likely to taste unpleasant. If excess quantities are swallowed this may give rise to gastric irritation as the product contains a surfactant, and general supportive therapy should be carried out if necessary.

Pharmaceutical precautions None known.

Legal category GSL.

Package quantities Tube containing 81 g.

ORTHO* Plastic Vaginal Applicator available separately.

Further information Nil.

Product licence number 0076/5007

ORTHO-NOVIN* 1/50 ORAL CONTRACEPTIVE TABLETS

Presentation White $\frac{1}{4}$ inch diameter, circular tablets with flat faces and bevelled edges, bearing on each face

the engraving 'ORTHO'. Each tablet contains 1 mg Norethisterone BP and 50 mcg Mestranol BP.

Uses Contraception and the recognised indications for such oestrogen/progestogen combinations.

Action: Through the mechanism of gonadotrophin suppression by the oestrogenic and progestational actions of the ingredients. Although the primary mechanism of action is inhibition of ovulation, alterations to the cervical mucus and to the endometrium may also contribute to the efficacy of the product.

Dosage and administration The basic dosage regimen is a 28-day cycle of 1 tablet daily for 21 days followed by seven tablet-free days. For initial therapy the first tablet is taken on the fifth day of the menstrual cycle, counting the first day of bleeding as Day 1. Each subsequent course is started after seven tablet-free days have followed the preceding course. Contraception can be initiated immediately post partum in the non-nursing patient. The possibility of ovulation and conception prior to the initiation of medication should be considered. The patient should be advised that during the first 14 days of the first course an additional reliable non-hormonal form of contraception should be used. If the patient misses more than one tablet she should begin taking tablets again as soon as remembered and an additional reliable method of contraception used until the next withdrawal bleed.

If the patient has vomiting or diarrhoea, absorption of the hormones will be impaired, making it advisable to use an additional reliable method of contraception until her next menstrual period. Should a bleeding fail to occur at the usual time, the possibility of pregnancy should be excluded before starting the next pack.

Contra-indications, warnings, etc

Contra-indications: Existing thrombophlebitis, thromboembolic disorders, cerebral vascular disease, myocardial infarction, or a past history of these conditions. Sickly-cell anaemia. Markedly impaired liver function. Congenital or existing disorders of lipid metabolism. Known or suspected carcinoma of the breast. Known or suspected oestrogen-dependent neoplasia. History during pregnancy of idiopathic jaundice, severe pruritis, shingles or deterioration of otosclerosis. Dubin-Johnson syndrome. Rotor syndrome. Undiagnosed abnormal genital tract bleeding. Known or suspected pregnancy.

Warnings: An increased risk of thrombophlebitis, cerebrovascular disorders, myocardial infarction and pulmonary embolism associated with the use of oral contraceptives has been reported in several retrospective case control studies. The increased risk has been estimated in these studies to be approximately 4 to 11 times higher (for cerebral haemorrhage two times higher) for users when compared to non users. This reported risk according to two of the studies is not related to duration of use nor does it persist after discontinuance according to one of the studies. An interim report of a large scale continuing prospective study has tended to confirm these retrospective studies for thrombophlebitis and possible cerebrovascular disorders. This study also reported that the risk of superficial and deep vein thrombosis was lower in women using preparations containing 50 mcg of oestrogen or less. There may not be full recovery from such disorders and it should be realised that in a few cases they are fatal.

Because of a possible increased risk of post surgery thromboembolic complications in oral contraceptive

users, therapy should be discontinued at least six weeks prior to elective surgery. Caution should be exercised in administering oestrogen/progestogen combinations to women with a history of hypertension. An increased risk of surgically confirmed gall bladder disease associated with the use of oral contraceptives has been reported in a retrospective case control study.

Liver tumours, occasionally fatal, have been reported in women using oral contraceptives. These tumours may present as an abdominal mass, intra-abdominal bleeding and/or with signs and symptoms of acute abdomen. These have been reported in short term as well as long term users of oral contraceptives.

A small fraction of the active ingredients in oral contraceptives has been identified in the milk of mothers receiving these drugs. The effects, if any, on the breast-fed child have not been determined. If possible the use of oral contraceptives should be deferred until the infant is weaned.

When women have taken hormones during pregnancy there have been some reports of the possibility of adverse effects on the developing child. A direct relationship between such effects and oral contraceptives has not been confirmed, but as with any other drug, avoidance of continuing oral contraception in early pregnancy is desirable. Therefore pregnancy should be ruled out before initiating or continuing the administration of oral contraceptives to patients who have missed one menstrual period.

Certain factors may entail some risk of thrombosis, e.g. smoking, obesity, varicose veins, cardiovascular diseases, diabetes, and migraine. The suitability of a combined oral contraceptive should be judged according to the severity of such conditions in the individual case, and should be discussed with the patient before she decides to take it. The risk of arterial thrombosis associated with combined oral contraceptives increases with age and this risk is aggravated by cigarette smoking. The use of combined oral contraceptives in women in the older age group, especially those who are cigarette smokers, should therefore be discouraged and alternative methods advised.

Reduced efficacy and increased incidence of breakthrough bleeding have been associated with concomitant use of oral contraceptives and rifampicin. A similar association has been suggested with oral contraceptives and barbiturates, phenylbutazone, phenytoin sodium and ampicillin.

Reasons for stopping oral contraceptives immediately: Early manifestations of thrombotic or thromboembolic disorders, thrombophlebitis, cerebrovascular disorders (including haemorrhage), myocardial infarction, pulmonary embolism or retinal thrombosis. Hypertension. Gradual or sudden, partial or complete loss of vision. Proptosis or diplopia. Onset or aggravation of migraine or development of headaches of a new pattern which are recurrent, persistent or severe. Papilloedema or any evidence of retinal vascular lesions. During periods of immobility (e.g. after accidents). Pregnancy. Manifestations of liver tumours.

Precautions: Examination of the pelvic organs, breasts and blood pressure should precede the prescribing of any oral contraceptive, and should be repeated regularly. The following are some of the medical conditions reported to be influenced by oral contraceptive therapy, and where the physician will have to exercise medical judgement to commence, continue or discontinue therapy as appropriate:

1. Pre-existing uterine fibromyomata may increase in size.
2. A decrease in glucose tolerance in a significant number of women.
3. An increase in blood pressure in a small but significant number of women.
4. Cholestatic jaundice. Patients with a history of cholestatic jaundice of pregnancy are more likely to develop cholestatic jaundice during oral contraceptive therapy.
5. Amenorrhoea during and after oral contraceptive therapy. Women with a past history of oligomenorrhoea or secondary amenorrhoea or women with irregular cycles may be more likely to remain anovulatory or to become amenorrhoeic post oral contraceptive therapy.
6. Depression.
7. Fluid retention. Conditions which might be influenced by this factor include epilepsy, migraine, asthma, cardiac or renal dysfunction.
8. Varicose veins.
9. Multiple sclerosis.
10. Porphyria.
11. Tetany.
12. Wearing of contact lenses

or any condition that is prone to worsen during pregnancy.

The following laboratory determinations may be altered in patients using oral contraceptives:

Hepatic: Increased BSP retention and other tests.

Coagulation: Increased prothrombin, Factors VII, VIII, IX and X; decreased antithrombin III; increased platelet aggregability.

Endocrine: Increased PBI and butanol extractable protein bound iodine and decreased T^3 uptake; increased glucose blood levels.

Other: Increased phospholipids and tri-glycerides, decreased serum folate values and disturbance in tryptophan metabolism. Decreased pregnanediol excretion, reduced response to metyrapone test.

These tests usually return to pre-therapy values after discontinuing oral contraceptive use. However, the physician should be aware that these altered determinations may mask an underlying disease.

Side-effects: Side-effects most commonly reported in early cycles of oral contraceptive therapy include breakthrough bleeding, spotting, nausea, vomiting and other gastro-intestinal disturbances. These frequently decrease with continued use. Other common side-effects include: change in menstrual flow, change in weight, oedema, chloasma (which may persist post therapy), amenorrhoea, breast changes (tenderness, enlargement and secretion).

In addition to the conditions and disorders discussed above, the following have been reported as adverse reactions in patients using combined oral contraceptives:

Neuro-ocular lesions
Rash
Cervical erosion and secretions
Suppression of lactation
Pre-menstrual-like syndrome
Changes in libido
Leg cramp
Relative pyridoxine deficiency
Haemorrhagic eruptions
Cystitis like syndrome
Headache
Nervousness

Fatigue
Hirsutism
Loss of scalp hair
Erythema multiforme
Erythema nodosum
Itching
Vaginal candidiasis
Porphyria

Overdosage: Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea, and withdrawal bleeding may occur in females. An appropriate method of gastric emptying may be used if considered desirable.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Carton containing 3 pushpaks each of 21 tablets – sufficient for 3 cycles.

Further information Nil.

Product licence number 0076/5000.

OVYSMEN* 0.5/35 ORAL CONTRACEPTIVE TABLETS

Presentation White $\frac{1}{2}$ inch diameter, circular tablets with flat faces and bevelled edges, bearing the engraving **ORTHO** on each face. Each tablet contains 0.5 mg Norethisterone BP and 35 mcg Ethinyloestradiol BP.

Uses Contraception and the recognised indications for such oestrogen/progestogen combinations.

Action: Through the mechanism of gonadotrophin suppression by the oestrogenic and progestational actions of the ingredients. Although the primary mechanism of action is inhibition of ovulation, alterations to the cervical mucus and to the endometrium may also contribute to the efficacy of the product.

Dosage and administration The basic dosage regimen is a 28-day cycle of 1 tablet daily for 21 days followed by seven tablet-free days. For initial therapy the first tablet is taken on the fifth day of the menstrual cycle, counting the first day of bleeding as Day 1. Each subsequent course is started after seven tablet-free days have followed the preceding course. Contraception can be initiated immediately post partum in the non-nursing patient. The possibility of ovulation and conception prior to initiation of medication should be considered. The patient should be advised that during the first 14 days of the first course an additional reliable non-hormonal form of contraception should be used. If the patient misses more than 1 tablet, she should begin taking tablets again as soon as remembered and an additional reliable method of contraception used until the next withdrawal bleed.

If the patient has vomiting or diarrhoea, absorption of the hormones will be impaired, making it advisable to use an additional reliable method of contraception until her next menstrual period. Should a bleeding fail to occur at the usual time, the possibility of pregnancy should be excluded before starting the next pack.

Contra-indications, warnings, etc

Contra-indications: Existing thrombophlebitis, thromboembolic disorders, cerebral vascular disease, myocardial infarction, or a past history of these conditions. Sick-cell anaemia. Markedly impaired liver function.

Congenital or existing disorders of lipid metabolism. Known or suspected carcinoma of the breast. Known or suspected oestrogen-dependent neoplasia. History during pregnancy of idiopathic jaundice, severe pruritus, shingles or deterioration of otosclerosis. Dubin-Johnson syndrome. Rotor syndrome. Undiagnosed abnormal genital tract bleeding. Known or suspected pregnancy.

Warnings: An increased risk of thrombophlebitis, cerebrovascular disorders, myocardial infarction and pulmonary embolism associated with the use of oral contraceptives has been reported in several retrospective case control studies. PEVARYL* CREAM

PEVARYL* LOTION

PEVARYL* SPRAY POWDER

Presentation *Cream:* A white cream containing 1% econazole nitrate.

Lotion: A white water-miscible lotion containing 1% econazole nitrate.

Spray Powder: A white powder containing 1% econazole nitrate, emitted as a spray by means of an aerosol container.

Uses Econazole nitrate is a broad-spectrum antifungal agent.

Cream: All fungal skin infections due to dermatophytes (e.g., *Trichophyton* species), yeasts (e.g., *Candida* species), moulds and other fungi. These include ringworm (tinea) infections, athlete's foot, paronychia, pityriasis versicolor, erythrasma and vulvitis, balanitis and napkin rash due to *Candida*.

Lotion: As Pevaryl Cream, but particularly suitable for hairy and moist areas and for fungal otitis externa.

Spray Powder: As Pevaryl Cream, but particularly suitable in intertriginous areas. Also for the protection of areas at risk and as yet unaffected by such infections.

Dosage and administration *Cream:* Apply to the affected area 2-3 times daily and rub in gently.

In nail infections, apply once daily and cover with an occlusive dressing.

Lotion: As for Pevaryl* Cream.

Spray Powder: Apply to the affected area twice daily until the lesions have healed.

In order to prevent relapse, treatment should be continued for 2 weeks after clinical cure.

Contra-indications, warnings, etc *Contra-indications:* None known.

Side effects: Rarely, transient local mild irritation may occur immediately after application.

Precautions: *Cream and Lotion:* Hypersensitivity has rarely been recorded, if it should occur, administration of the product should be discontinued.

Spray Powder: As for Pevaryl Cream and Pevaryl Lotion. The spray should be kept away from the eyes and mucous membranes.

Overdosage: Pevaryl Cream, Lotion and Spray Powder are intended for topical use. If accidental ingestion of large quantities of the product occurs, an appropriate method of gastric emptying may be used if considered desirable.

Pharmaceutical precautions

Cream and Lotion: None.

Spray Powder: Shake well before use. Contents are under pressure. Store in a cool place away from heat and sunlight; do not burn or puncture, even when empty.

Legal category

Cream: P.

Lotion: P.

Spray Powder: P.

Package quantities *Cream:* Each tube contains 30 g.

Lotion: Each bottle contains 30 ml.

Spray Powder: 200 g aerosol can contains 20 g econazole nitrate powder 1%.

Further information The infected area should be kept clean and dry during treatment.

Pevaryl Spray Powder is suitable for use in conjunction with Pevaryl Cream or Pevaryl Lotion. It is also useful for the treatment of clothing such as shoes and socks in cases of tinea pedis.

Cream: 0076/0059

Lotion: 0076/0066

Spray powder 0076/0063

RETIN-A* ACNE TREATMENT

Presentation Retin-A* Acne Treatment is available as either a clear yellow solution of 0.025% w/w tretinoin

supplied in amber bottles or in tubes of tretinoin gel 0.025% w/w or tretinoin cream 0.05% w/w.

Uses For topical application in the treatment of acne vulgaris in which comedones, papules and pustules predominate.

Retin-A Lotion is best suited for large areas such as the back.

Retin-A Gel is best suited for severe acne, for initial therapy and for oily and dark skin.

Retin-A Cream is best suited for use on dry and fair skin.

Dosage and administration Retin-A Acne treatment should be applied once or twice daily to the area of skin where acne lesions occur. Only apply sufficient to cover the affected area lightly, using a gauze swab, cotton wool or the tips of clean fingers. Avoid over-saturation to the extent that excess medication could run into eyes, angles of the nose or other areas where treatment is not intended.

Initial application may cause transitory stinging and a feeling of warmth. The correct frequency of administration should produce no more than an erythema similar to that of mild sunburn. In patients with sensitive skin, application once daily may be sufficient. In patients with normal skin, increasing the frequency of application to twice daily is usually necessary.

If Retin-A is applied excessively, no more rapid or better results will be obtained and marked redness, peeling or discomfort may occur. Should this occur accidentally or through over-enthusiastic use, application should be discontinued for a few days.

Patience is needed in this treatment, since therapeutic effects will not usually be observed until after 6-8 weeks of treatment. During the early weeks of treatment, an apparent exacerbation of inflammatory lesions may occur. This is due to the action of the medication on deep, previously unseen comedones and papules. Once the acne lesions have responded satisfactorily, it should be possible to maintain the improvement with less frequent applications.

Cosmetics may be used, but the areas to be treated should be thoroughly washed beforehand. Astringent toiletries should be avoided.

Contra-indications, warnings, etc Use of the product should be discontinued if hypersensitivity to any of the ingredients should occur. Retin-A Acne Treatment should be kept away from the eye and eyelids, the mouth and other mucous membranes. Care should also be taken not to let the medication accumulate in folds of the skin and the angles of the nose. Retin-A should not be applied to eczematous skin, nor to cuts and abrasions.

Retin-A should not be used concomitantly with other skin medications, particularly those containing peeling agents such as sulphur, resorcinol, benzoylperoxide or salicylic acid.

Recent studies in mice treated with the active ingredient (tretinoin) of Retin-A and exposed to artificial sunlight suggest that tretinoin may speed up the appearance of sunlight induced skin tumours. Laboratory mice treated with tretinoin but not exposed to sunlight did not develop skin tumours. The significance of these studies as related to human beings is unknown. However it is important to avoid or minimise exposure of Retin-A treated areas to sunlight or sunlamps during the course of treatment.

Retin-A should not be used in patients with a personal or family history of cutaneous epithelioma.

Side effects: The application of excessive amounts of Retin-A to the skin may cause severe erythema, irritation and discomfort. Should this occur, the frequency of application should be reduced or the use of Retin-A discontinued temporarily. Temporary hypo or hyperpigmentation has been reported in a few individuals treated with Retin-A. All side effects so far reported have been reversible upon discontinuation of Retin-A therapy.

Overdosage: Retin-A is intended for topical use only. Excessive use is dealt with under side effects. Taken orally by mischance Retin-A is liable to taste unpleasant. Unless the amount is small an appropriate method of gastric emptying should be used as soon as possible.

Pharmaceutical precautions Store in a cool place. The 80 ml bottle of lotion should be protected from light and any remaining medicine discarded on completion of treatment.

Legal category POM.

Package quantities *Lotion:* Amber glass bottle containing 80 ml.

Gel and Cream: Tubes containing 60 g.

Further information Nil.

Lotion 0076/0037

Gel 0076/0050

Cream 0076/0056

SULTRIN* TRIPLE SULFA CREAM

Presentation A white, non-staining cream containing Sulphathiazole 3.42% w/w, Sulphacetamide 2.86% w/w and Sulphabenzamide 3.70% w/w.

Uses For the treatment of infections caused by *Haemophilus Vaginalis* and non-specific bacterial vaginitis and cervicitis. It may also be used in the prevention of bacterial complications following cervical and vaginal surgery and vulvectomy and as an anti-infective in the post-partum state.

Dosage and administration One applicatorful intra-vaginally twice daily for 10 days. The dosage may then be reduced to once a day if necessary.

Contra-indications, warnings, etc Sulphonamide sensitivity and kidney disease.

Overdosage: Sultrin Triple Sulfa Cream is intended for intravaginal use. If accidental ingestion of large quantities of the product occurs, an appropriate method of gastric emptying may be used if considered desirable. Elimination of sulphonamides in the urine may be assisted by giving alkalis such as sodium bicarbonate and increasing fluid intake.

Pharmaceutical precautions Store at room temperature, avoid excessive heat.

Legal category POM.

Package quantities Tube containing 78 g with or without the ORTHO* Plastic Vaginal Applicator.

Further information The three sulphonamides exert optimal bacteriostatic action at different specific pH levels. The point of optimal activity for each drug is:

Sulphathiazole pH 7.0

Sulphacetamide pH 5.2
Sulphabenzamide pH 4.6

Product licence number 0076/5012.

SULTRIN* VAGINAL TABLETS

Presentation Sultrin Vaginal Tablets are white, non-staining, water-dispersible, lozenge-shaped tablets engraved with the Ortho shield design. Each tablet contains:

Sulphathiazole 172.5 mg
Sulphacetamide 143.75 mg
Sulphabenzamide 184.0 mg

in a rapidly disintegrating base.

Uses For the treatment of infections caused by *Haemophilus vaginalis* and non-specific bacterial vaginitis and cervicitis. It may also be used in the prevention of bacterial complications following cervical and vaginal surgery and vulvectomy and as an anti-infective in the post-partum state.

Dosage and administration One tablet placed high in the vagina twice daily for 10 days. Repeat if necessary.

Contra-indications, warnings, etc Sulphonamide sensitivity; renal disease.

Overdosage: Sultrin Vaginal Tablets are intended for intravaginal use. If accidental ingestion of large quantities of the product occurs, an appropriate method of gastric emptying may be used if considered desirable. Elimination of sulphonamides in the urine may be assisted by giving alkalis such as sodium bicarbonate and increasing fluid intake.

Pharmaceutical precautions None known.

Legal category POM.

Package quantities Packages of 20 foil-wrapped tablets with vaginal applicator.

Further information The three sulphonamides exert optimal bacteriostatic action at different specific pH levels. The point of optimal activity for each drug is:

Sulphathiazole pH 7.0
Sulphacetamide pH 5.2
Sulphabenzamide pH 4.6

Product licence number 0076/5013.

TOLECTIN* TABLETS ▼ TOLECTIN* DS CAPSULES

Presentation *Tablets:* White, flat, circular tablet (12 mm diameter) with bevelled edges. The word TOLECTIN is engraved on one side with a score line on the reverse. For oral administration.

Tolectin (tolmetin sodium) 200 mg tablets each contain 246 mg of tolmetin sodium dihydrate, which is equivalent to 200 mg tolmetin. Each tablet contains 18 mg (0.784 m Eq) of sodium.

Capsules: A size 'O' hard gelatin capsule with an ivory opaque body and a light blue opaque cap containing a yellow powder. For oral administration.

Tolectin (tolmetin sodium) 400 mg capsules each contain 490 mg of tolmetin sodium dihydrate, which is equivalent to 400 mg of tolmetin. Each capsule contains 36 mg (1.568 m Eq) of sodium.

Uses Tolectin is a non-steroidal anti-inflammatory

agent with analgesic and antipyretic properties. It is indicated for:

rheumatoid arthritis
juvenile rheumatoid arthritis (Still's Disease)
osteoarthritis
ankylosing spondylitis
peri-articular disorders such as fibrositis and bursitis

Dosage and administration The initial adult dosage is 400 mg three times daily. This may be adjusted within the range 600–1800 mg daily in 2, 3 or 4 divided doses depending on patient response and the severity of the disease.

In juvenile rheumatoid arthritis the dosage is 20–25 mg/kg/day in 3–4 divided doses. The maximum dose is 30 mg/kg/day or 1800 mg/day whatever the body weight. Half a tablet (100 mg) is a suitable unit for most children's doses.

Contra-indications, warnings, etc *Contra-indications:* active peptic ulcer; previous sensitivity to Tolectin, aspirin, or other non-steroidal anti-inflammatory agents, which have induced symptoms of asthma, rhinitis or urticaria.

Warnings: Tolectin should be used with caution in patients with a history of upper gastrointestinal tract disease. Tolectin prolongs bleeding time and patients who may be adversely affected should be carefully monitored during Tolectin therapy.

No teratogenic effects have been found in animals, but, as in the case of all new drugs, caution should be exercised in the prescribing of Tolectin to pregnant women. Safety for use during pregnancy or lactation has not been established.

Renal papillary necrosis has occurred in animals after long term administration although there has been no evidence of renal toxicity in clinical trials. However, since Tolectin is eliminated primarily by the kidneys, caution should be observed and patients with impaired renal function should be closely monitored and may require lower doses.

In patients with rheumatoid arthritis who have received certain anti-rheumatic drugs, eye changes have been observed. During clinical studies of up to 2 years with Tolectin no such changes have occurred.

Side effects: epigastric discomfort, headache (rare), water and sodium retention, skin rash. Gastro-intestinal disturbance may occur but blood loss due to Tolectin is rare.

Small and transient decreases in haemoglobin and haematocrit not associated with gastrointestinal bleeding have occurred. A few cases of granulocytopenia have been observed.

Management of overdosage: In the event of overdosage, the stomach should be emptied by inducing vomiting or by gastric lavage followed by the administration of activated charcoal. Studies in rats indicate that the urinary excretion of the drug is enhanced when the urine is made alkaline with sodium bicarbonate.

Pharmaceutical precautions *Tablets and Capsules:* Extremes of temperature and humidity should be avoided.

Legal category POM.

Package quantities Containers of 100 and 250 tablets
Container of 100 capsules.

Further information In clinical trials Tolectin has

shown no interaction with concomitantly administered drugs, such as gold, corticosteroids and paracetamol.

Preliminary studies indicate that Tolectin does not interact with anti-coagulant drugs.

In adult diabetic patients under treatment with either sulphonylureas or insulin no changes have been observed in the clinical effects of either Tolectin or the hypoglycaemic agents.

The metabolites of tolmetin in urine have been found to give positive tests for proteinuria using tests which rely on acid precipitation as their endpoint. No interference is seen in the tests for proteinuria using dye-impregnated commercially available reagent strips.

Tablets: 0076/0021

Capsules: 0076/0075

ZOMAX* TABLETS ▼

Presentation Pale yellow flat faced irregular hexagon shaped tablets, scored, bevelled, imprinted ORTHO on one side and imprinted ZOMAX on the reverse.

Each Zomax 100 mg tablet contains 120 mg zomepirac sodium dihydrate equivalent to 100 mg zomepirac. Each 100 mg tablet contains 8 mg (0.34 mEq) of sodium.

Uses Zomax is indicated for the treatment of pain associated with the following conditions:

Post traumatic pain related to musculoskeletal injury.

Pain in osteoarthritis and rheumatoid arthritis.

Post operative pain following orthopaedic surgery.

Post operative pain following general surgery.

Pain secondary to oral surgery.

Post partum episiotomy pain.

Pain secondary to malignancy.

Dysmenorrhoea.

Dosage and administration The recommended oral dose of Zomax is 100 mg every 4-6 hours as required. Dosage may be adjusted to the patient's response. Dosages larger than 600 mg per day have not been studied and are not recommended. Single doses larger than 100 mg have not been adequately studied and are not recommended.

Contra-indications, warnings, etc Zomax should not be used in patients in whom salicylates or other non-steroidal anti-inflammatory drugs induce bronchospasm, rhinitis, urticaria, or other sensitivity reactions.

As with other non-steroidal anti-inflammatory drugs, anaphylactoid reactions have been reported. Because of the possibility of cross-sensitivity due to structural relationships which exist among non-steroidal anti-inflammatory drugs anaphylactoid reactions may be more likely to occur in patients who have exhibited allergic reactions to these compounds, particularly tolmetin sodium. Patients presenting with an allergic reaction to Zomax should be evaluated as to the severity of the reaction and treated appropriately with conventional therapy. This may include the use of epinephrine, antihistamines, pressors, fluids, and/or steroids.

Peptic ulceration and gastrointestinal bleeding have rarely been reported in patients receiving Zomax tablets. However, the drug should be given under close super-

vision to patients with a history of these disorders, and should be avoided in patients with active peptic ulcer.

Although zomepirac sodium has a more transient effect on bleeding time than aspirin, it is an inhibitor of platelet function; therefore, as with aspirin, patients who have coagulation disorders should be carefully observed when Zomax is administered.

As with other non-steroidal anti-inflammatory drugs, elevations of BUN and serum creatinine have been reported with Zomax administration. Therefore, periodic kidney function tests are recommended for those patients undergoing long-term treatment with Zomax. Rarely, acute renal failure has been reported in patients receiving Zomax.

Since Zomax is eliminated primarily by the kidneys, patients with impaired renal function should be closely monitored and lower doses of Zomax used.

Rarely, in long-term studies, reversible elevations of liver enzymes have occurred.

Zomax is not recommended during pregnancy or lactation since safety in pregnant women or nursing mothers has not been established.

The safety and effectiveness of Zomax has not been established in children under the age of 12 years, and the use of Zomax in children is not recommended.

Side effects: Zomax is a well tolerated drug and the side effect incidence is low.

Adverse reactions were usually mild and as with other products of this type incidence was nearly always lower during short term therapy. The most common side effects were related to the gastrointestinal tract and included nausea, GI distress, diarrhoea, abdominal pain and dyspepsia. Dizziness, oedema and allergic reactions have been reported, rarely.

Management of overdosage: The absence of experience with acute overdosage precludes characterization of sequelae and assessment of antidotal efficacy at this time. It is reasonable to assume, however, that the standard practices of gastric evacuation, activated charcoal administration, and general supportive therapy would apply.

Pharmaceutical precautions None known.

Legal category POM.

Package quantities Containers of 100 tablets.

Further information The binding of warfarin to human plasma proteins is unaffected by Zomax.

Zomax produces significant analgesia within a $\frac{1}{2}$ hour and maximum analgesia within 1-2 hours following oral administration. The duration of analgesia is generally 4 to 6 hours.

Zomax is a non-narcotic, non-addicting analgesic, and in adequate and well controlled clinical studies no patient tolerance to the drug has been observed.

Since antacids do not interfere with the bioavailability of zomepirac, Zomax may be administered with antacids (other than bicarbonate) if gastrointestinal symptoms occur.

Product licence number 0076/0073.

DALIVIT*

Presentation *Capsules:* Oval red, soft gelatine capsules containing oily yellow suspension.

Drops: Deep yellow liquid with a characteristic taste and odour.

Syrup: Pale yellow liquid with a characteristic taste and odour

Formula	Capsules	Drops	Syrup
Vitamin A	10,000 i.u.	5,000 i.u.	5,000 i.u.
Vitamin D	1,000 i.u.	400 i.u.	1,000 i.u.
Thiamine Hydrochloride BP	—	1 mg	2.5 mg
Thiamine Mononitrate USP	3 mg	—	—
Riboflavin BP	3 mg	0.4 mg	1 mg
Pyridoxine Hydrochloride BP	1 mg	0.5 mg	1 mg
Ascorbic Acid BP	75 mg	50 mg	25 mg
Nicotinamide BP	25 mg	5 mg	10 mg
Calcium pantothenate	5 mg	—	5 mg
	in each capsule	in each 0.6 ml	in each 5 ml

Actions and uses *Drops:* These are intended principally for administration to infants and very young children for the prevention and treatment of vitamin deficiency states and for the maintenance of normal health and growth in early childhood.

Capsules and syrup: For the prevention and treatment of vitamin deficiency in older children and adults. Indicated during pregnancy and lactation, in febrile and infective conditions or to provide essential vitamins for patients on restricted diets.

Dosage and administration *Adults:* 1 Dalivit Capsule or 15 ml Dalivit Syrup daily. In febrile conditions, in pregnancy and during lactation or in the presence of infection, requirements of vitamins are increased beyond the normal so 3 capsules or 30 ml syrup daily may be required.

Infants: Prophylaxis. Drops.

Up to 12 months: 0.3 ml daily.

Over 12 months: 0.6 ml daily.

In conditions of impaired absorption or frank vitamin deficiency, these doses may be increased at the discretion of the physician.

Contra-indications, warnings, etc Hypersensitivity to any of the active ingredients is a contra-indication. Excessive doses of vitamins A and D can lead to hypervitaminosis. When multivitamin preparations are prescribed allowance must be made for vitamins from other sources.

Pharmaceutical precautions *Capsules:* Store in a cool place.

Drops: Store below 8°C—refrigerate.

Syrup: Store in a cool place protected from light.

GONADOTRAPHON LH*

Presentation Gonadotrophon LH is presented as ampoules containing a sterile, white, freeze-dried plug of 500 i.u., 1,000 i.u. or 5,000 i.u. of Chorionic Gonadotrophin BP for injection in a Lactose BP base. All strengths are packed with 2 ml ampoules of solvent.

Actions and uses *In the male:* Delayed puberty, cryptorchidism, oligospermia or aspermia with inactive testes.

In the female: Induction of ovulation, menorrhagia due to persistent follicular phase, recurrent abortion.

Dosage and administration Intramuscular injection.

Delayed puberty: 500 i.u. twice weekly. *Cryptorchidism:* Treat before age of puberty. Not indicated for ectopic testis. Optimum age range for treatment is 7–10 years. 500 i.u. thrice weekly for 6–10 weeks depending upon response. Oligospermia or aspermia with inactive testes: 500 i.u. twice or thrice weekly for 12–16 weeks.

Induction of ovulation: In conjunction with Serum Gonadotrophin. Gonadotrophon FSH (Serum Gonadotrophin BP) 500 i.u. intramuscularly daily from 5th to 14th day of cycle followed by Gonadotrophon LH 500 i.u. daily from 15th to 24th day of cycle.

Menorrhagia due to persistent follicular phase: 1000 i.u. twice weekly for last 2 weeks of cycle. Recurrent abortion: 1000 i.u. to 2000 i.u. twice weekly from earliest evidence of pregnancy to 14th week of gestation.

Contra-indications, warnings, etc If pregnancy follows treatment with Gonadotrophon LH and FSH the likelihood of multiple births is greater than usual.

Pharmaceutical precautions Aqueous solutions of gonadotrophic hormones are unstable but the dry-filled ampoules will remain stable if stored at a temperature not exceeding 20°C.

Legal category POM.

Package quantities Box of 5 or 50 twin ampoules (powder and solvent) 500 i.u. and 1,000 i.u. Single ampoule and boxes of 5 (powder and solvent) 5,000 i.u.

Further information Nil.

HEPARIN INJECTION BP (PABYRN)

Presentation A sterile, pyrogen-free, clear, colourless solution for injection supplied in multidose vials containing Heparin Sodium BP (Mucous) in concentrations of 1,000, 5,000 or 25,000 i.u. per ml. Also available in single dose ampoules without preservative.

Actions and uses Heparin has an anticoagulant action and its principal use is in the prophylaxis and treatment of thrombo-embolic disorders. It is of particular value in the treatment of deep vein thrombosis following major surgery and is used routinely in extra corporeal circulation procedures involving heart-lung and renal dialysis machines.

Dosage and administration An initial intravenous injection of 12,500 units followed by 7,500–10,000 units at four hourly intervals as required. May also be administered by continuous infusion via Dextrose/Saline Solutions. The aim of treatment is to extend clotting time to about 15 minutes, which is two to three times the normal rate. In the prophylaxis and treatment of post-operative deep vein thrombosis, a subcutaneous dose of 5,000 i.u. two hours pre-operatively followed by 5,000 i.u. every 8–12 hours for 7–10 days.

Contra-indications, warnings, etc Heparin is contra-indicated in haemophilia, purpura and other haemorrhagic states. Also in bacterial endocarditis, gastric and duodenal ulcers, threatened abortion and advanced renal or hepatic disease.

Haemorrhage due to overdosage can often be controlled by discontinuing Heparin therapy. Severe bleeding may be reduced by administering 1 mg of protamine sulphate for each 100 units of Heparin to be neutralised. Hypersensitivity reactions are rare.

Pharmaceutical precautions Heparin injections should be stored in a cool place protected from light and should not be used after expiry date indicated. As Heparin loses potency in solutions with a pH less than 6 (e.g. Dextrose 5%) it should only be added to such solutions immediately prior to infusion. Heparin is incompatible in aqueous solutions with certain substances including antibiotics, antihistamines, phenothiazines, narcotic analgesics, hydrocortisone and hyaluronidase.

Legal category POM.

Package quantities 1 and 5 ml ampoules and 5 ml r/c vials containing 1,000, 5,000 or 25,000 i.u. per ml. All in packs of 10. Also ampoule containing 5,000 i.u. in 0.2 ml.

Further information Nil.

KETOVITE* TABLETS

Presentation Yellow tablets. Each Ketovite Tablet contains:

Thiamine hydrochloride	1.0 mg
Riboflavin	1.0 mg
Pyridoxine hydrochloride	0.33 mg
Nicotinamide	3.3 mg
Calcium pantothenate	1.16 mg
Ascorbic acid	16.6 mg
α -Tocopheryl acetate	5.0 mg
Inositol	50.0 mg
Biotin	0.17 mg
Folic acid	0.25 mg
Acetomenaphthone	0.5 mg

Action and uses The artificial nature of many therapeutic diets will inevitably mean that certain essential vitamins will not be available from food and these must, therefore, be provided in an acceptable alternative form. It is for this purpose that Ketovite Tablets have been devised. Ketovite Tablets do not contain any sucrose, glucose, fructose, lactose, starch, sodium or artificial colouring material and may be used in conjunction with Ketovite (Supplement) Liquid to provide complete vitamin supplementation in conditions such as galactosaemia, disaccharide intolerance, phenylketonuria and other disorders of carbohydrate or amino-acid metabolism involving the use of synthetic foods. Ketovite Tablets are also of value to supplement other restricted diets, such as those used in renal conditions and malabsorption states.

Note: This is not a substitute for Ketovite (Supplement) Liquid.

Dosage and administration As a complete vitamin supplement for infants, young children or adults on restricted or synthetic diets: 1 Ketovite Tablet three times a day *plus* 5 ml Ketovite (Supplement) Liquid daily.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store in a cool dry place and use before the expiry date indicated.

Legal category POM.

Package quantities 100, 500.

Further information Nil.

Product licence number 0051/5079.

KETOVITE* (SUPPLEMENT) LIQUID

Presentation Pale pink liquid. Each 5 ml dose of Ketovite (Supplement) Liquid contains:

Vitamin A	2,500 units
Vitamin D	400 units
Choline chloride	150 mg
Cyanocobalamin	12.5 mcg

Action and uses The artificial nature of many therapeutic diets will inevitably mean that certain essential vitamins will not be available from food and these must, therefore, be provided in an acceptable alternative form.

It is for this purpose that Ketovite (Supplement) Liquid has been devised. Ketovite (Supplement) Liquid does not contain any sucrose, glucose, fructose, lactose, starch, sodium or artificial colouring material and may be used in conjunction with Ketovite Tablets to provide complete vitamin supplementation in conditions such as galactosaemia, disaccharide intolerance, phenylketonuria and other disorders of carbohydrate or amino-acid metabolism involving the use of synthetic foods. Ketovite is also of value to supplement other restricted diets, such as those used in renal conditions and malabsorption states.

Note: This is not a substitute for Ketovite Tablets.

Dosage and administration As a complete vitamin supplement for infants, young children or adults on restricted or synthetic diets: 5 ml Ketovite (Supplement) Liquid daily *plus* 1 Ketovite Tablet three times a day.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store between 5°C and 15°C and use before expiry date shown on label. Dilute if required with distilled water and use the diluted preparation within seven days.

Legal category P.

Package quantities 100 ml, 500 ml.

Further information Nil.

Product licence number 0051/5080.

PABRINEX*

Presentation Pairs of amber ampoules of Vitamins B and C Injection BPC for intravenous and intramuscular injection:

I/V High Potency – 5 ml No. 1 + 5 ml No. 2 Printed Blue
I/M High Potency – 5 ml No. 1 + 2 ml No. 2 Printed Red
I/M Maintenance – 2 ml No. 1 + 2 ml No. 2 Printed Pink

Active ingredients:

Uses Rapid therapy of severe depletion or malabsorption of the water soluble vitamins B and C, particularly in alcoholism, after acute infections, post-operatively and in psychiatric states.

Also used to maintain levels of Vitamins B and C in patients on chronic intermittent haemodialysis.

Dosage and administration

Intravenous: The contents of each pair of ampoules (total 10 ml) are drawn up into a syringe to mix them just before use, then injected slowly into a vein. For drip injection dilute with normal saline. *Not for intramuscular use.*

Intramuscular: The contents of each pair of ampoules (total: 7 ml – High Potency, 4 ml – Maintenance) are drawn up into a syringe to mix them just before use, then injected slowly high into the gluteal muscles, 5 cm below the iliac crest. *Not for intravenous use.*

Adult dose: Pabrinex is indicated for rapid therapy of severe vitamin depletion or malabsorption reported to occur in the following conditions:

Coma or delirium from alcohol, narcotics or barbiturates; collapse following continuous narcosis. The contents of 2–3 pairs of ampoules Intravenous High Potency (Blue No 1 and No 2) injected at intervals of 8 hours or at the discretion of the physician.

Psychosis following narcosis or ECT; toxicity from acute infections. The contents of one pair of ampoules Intravenous High Potency (Blue No 1 and No 2) or Intramuscular High Potency (Red No 1 and No 2) twice daily for up to 7 days.

Psychiatric states due to continued ill-health, old age, post operative debility and chronic infections; stress conditions. The contents of one pair of ampoules Intramuscular Maintenance (Pink No 1 and No 2) twice daily until maximum improvement is observed and maintained.

Haemodialysis. The contents of one pair of ampoules Intravenous High Potency (Blue No 1 and No 2) every

Dose Volume	10 ml		7 ml		4 ml	

(* provides 2% w/v in mixed ampoules)

(† provides 10% w/v in mixed ampoules)

two weeks diluted with saline and given at the end of the dialysis.

Children's dose: Pabrinex is rarely indicated for administration to children, but suitable doses are:

Under 6 years	– $\frac{1}{4}$ adult dose
6–10 years	– $\frac{1}{3}$ adult dose
10–14 years	– $\frac{1}{2}$ – $\frac{2}{3}$ adult dose
14 years and over	– adult dose

Contra-indications, warnings, etc Sensitivity to any of the vitamins present, though this is rarely encountered. Occasionally hypotension or mild paraesthesia may result from continued high doses of Thiamine (Vitamin B₁), but this may be counteracted by the simultaneous injection of 25 mg of d-Calcium Pantothenate.

Pharmaceutical precautions Store in a cool place and protect from light.

Legal category POM.

Package quantities Packs of 5 pairs and 10 pairs of ampoules.

Further information Nil.

Free protease	1.4 BP units
Lipase	25 BP units
Amylase	30 BP units

Pancrex V Capsules: Ivory coloured opaque hard gelatine capsules imprinted 'Pancrex V' and company logo.

Containing Pancreatin BP and providing not less than the following activity per capsule:

Free protease	430 BP units
Lipase	8,000 BP units
Amylase	9,000 BP units

The capsules provide a simple and convenient method of dose measurement of the powder for administration to younger children.

Pancrex V Tablets: (Pancreatin Tablets BP). White sugar and enteric coated tablets each containing not less than the following activity:

Free protease	110 BP units
Lipase	1,900 BP units
Amylase	1,700 BP units

Pancrex V Forte Tablets: (Pancreatin Tablets BP). White sugar and enteric coated tablets each containing not less than the following activity:

Free protease	330 BP units
Lipase	5,600 BP units
Amylase	5,000 BP units

Pancrex Granules: (Pancreatin Granules BP). Enteric coated granules containing not less than the following activity in each gram:

Free protease	300 BP units
Lipase	5,000 BP units
Amylase	4,000 BP units

Action and uses To compensate for reduced intestinal enzyme activity in pancreatic deficiency states.

Indications: Fibrocystic disease of the pancreas, chronic pancreatitis and pancreatic steatorrhoea following pan-createctomy, vagotomy or gastrectomy.

Dosage and administration It is generally accepted that dosage may vary considerably according to the needs of the individual patient, but the following dosage scale provides a suitable basis for adjustment.

Pancrex V Powder: $\frac{1}{2}$ –2 g swallowed dry or mixed with a little water or milk, four times daily before meals.

Pancrex V Capsules: Infants: The contents of 1–2 capsules mixed with feeds.

Older children and adults: The contents of 2–3 capsules four times daily before meals, or sprinkled on food at mealtimes. They may also be swallowed.

Pancrex V Tablets: 5–15 tablets four times daily before meals.

Pancrex V Forte Tablets: 2–6 tablets four times daily before meals.

Pancrex Granules: 5–10 g, swallowed dry or mixed with a little water or milk, four times daily before meals.

Contra-indications, warnings, etc *Cautionary note:* In the case of newborn infants, a dose of from 0.25 to 0.5 g of Pancrex V may be indicated, and it is possible that with this dosage some irritation of the skin surrounding the mouth and the anus may occur. A barrier cream will effectively prevent such local irritation.

If Pancrex V powder is mixed with liquids or feeds the resulting mixture should not be allowed to stand for more than one hour prior to use.

Pharmaceutical precautions The preparations should be stored in a well-closed container in a cool place and used before the expiry date indicated on the label.

Legal category GSL.

Package quantities *Pancrex V Powder:* 100 g and 250 g.

Pancrex V Tablets: 100 and 500.

Pancrex V Forte Tablets: 100 and 500.

Pancrex V Capsules: 100 and 500.

Pancrex Granules: 100 g and 500 g.

Further information Nil.

PARKE-DAVIS

BENAFED*

Presentation Orange/red linctus. Each 5 ml contains

Diphenhydramine Hydrochloride PhEur	12.5 mg
Dextromethorphan Hydrobromide PhEur	15 mg
Pseudoephedrine Hydrochloride BP	30 mg
Ammonium Chloride PhEur	125 mg
Sodium Citrate PhEur	57 mg
Menthol BP	1 mg

Action Non-narcotic, antitussive, decongestant and expectorant to give comprehensive relief to the coughing patient.

Indications Benafed is indicated for the relief of cough and its congestive symptoms and in the treatment of hay fever and other allergic conditions affecting the upper respiratory tract.

Dosage and administration Oral.

Adults: One 5 ml spoonful every four to six hours.

Children: 4-12 years: Half to one 5 ml spoonful every six hours.

2-4 years: 1.25 ml every six hours.

Recommended diluent Syrup BP. When diluted use within 14 days of preparation.

Contra-indications, warnings, etc Contra-indicated in patients with known hypersensitivity to any of the active constituents and in those receiving monoamine oxidase inhibitors, or within 14 days of stopping such treatment. Renal dysfunction. Caution may be necessary in patients with cardiovascular disease, hyperthyroidism, and prostatic enlargement. This preparation may cause drowsiness. If affected the patient should not drive or operate machinery. Avoid alcoholic drink, as this product potentiates the effects of alcohol and other CNS depressants.

As with any other medicine, care should be taken in administration during pregnancy.

Treatment of overdose: Gastric lavage in the conscious patient and intensive supportive therapy when necessary, as with cases of overdose with antihistaminic drugs.

Pharmaceutical precautions Keep container tightly closed.

Recommended diluent Syrup BP. When diluted use within 14 days of preparation.

Legal category P.

Package quantities 500 ml and 2.25 litres.

Further information Nil.

Product licence number 0018/0071

BENYLIN* DECONGESTANT

Presentation A clear yellow syrup with a honey and lemon flavour.

Each 5 ml contains:

Diphenhydramine hydrochloride PhEur	14.0 mg
Pseudoephedrine hydrochloride BP	10.0 mg
Sodium citrate PhEur	57.0 mg
Menthol BP	1.1 mg

Action The antihistaminic action of diphenhydramine hydrochloride helps to provide relief from nasal stuffiness, sneezing and watering of the eyes; the antitussive action suppresses the cough reflex and the local anaesthetic action helps to ease sore throats.

Pseudoephedrine combats the congestive symptoms that frequently accompany the cough and reduces bronchial and nasal congestion.

Indications For relief of cough and its congestive symptoms; particularly suitable for coughs associated with colds.

Dosage and administration Oral.

Adults: Two 5 ml spoonfuls four times a day.

Children: 6-12 years: One 5 ml. spoonful four times a day.

1-5 years: Half a 5 ml spoonful four times a day.

Contra-indications, warnings, etc Contra-indicated in patients with known hypersensitivity to any of the active constituents and in those receiving monoamine oxidase inhibitors or having received them within the previous fourteen days. Caution may be necessary in patients with cardiovascular disease, hyperthyroidism, and prostatic enlargement.

This preparation may cause drowsiness. If affected, the patient should not drive or operate machinery. Avoid alcoholic drink, as this product potentiates the effect of alcohol and other CNS depressants.

As with any other medication care should be taken in administration during pregnancy.

Treatment of overdose: Gastric lavage in the conscious patient and intensive supportive therapy when necessary as with cases of overdose with antihistaminic drugs.

Pharmaceutical precautions Keep container tightly closed.

Recommended diluent: Syrup BP. When diluted use within 14 days of preparation.

Legal category P.

Package quantities 500 ml, 2.25 L.

Further information Nil.

Product licence number 0018/0110.

BENYLIN* EXPECTORANT

Presentation A clear red syrup. Each 5 ml contains

Diphenhydramine Hydrochloride PhEur	14 mg
Ammonium Chloride PhEur	135 mg

Sodium Citrate PhEur
Menthol BP

57 mg
1.1 mg

Action Benylin Expectorant gives comprehensive relief to the coughing patient since it combines the antihistaminic and anticholinergic actions of Benadryl* (Diphenhydramine Hydrochloride BP) with selected expectorant and demulcent agents. It makes the cough more productive by loosening tenacious bronchial mucus. It combats the congestive symptoms that frequently accompany the cough and reduces bronchial and nasal congestion. Benylin Expectorant contains no opiate drugs.

Indications For the relief of cough and its congestive symptoms. It also alleviates histamine-induced bronchoconstriction.

Dosage and administration Oral.

Adults: One or two 5 ml spoonfuls every two or three hours.

Children: 1-5 years: Half 5 ml spoonful every three or four hours.

6-12 years: One 5 ml spoonful every three or four hours.

Contra-indications, warnings, etc Known hypersensitivity to any of the active constituents. Renal dysfunction. May cause drowsiness. If affected, the patient should not drive or operate machinery. Avoid alcoholic drink.

As with any other medicine, care should be taken in administration during pregnancy.

Treatment of overdose: Gastric lavage in the conscious patient and intensive supportive therapy where necessary, as with cases of overdose of antihistaminic drugs.

Pharmaceutical precautions Keep container tightly closed.

Recommended diluent – Syrup BP. When diluted use within 14 days of preparation.

Legal category P.

Package quantities 125 ml, 250 ml and 2.25 litres.

Further information Nil.

Product licence number 0018/5090.

BENYLIN* WITH CODEINE

Presentation A clear red syrup. Each 5 ml contains:

Diphenhydramine Hydrochloride PhEur	14 mg
Codeine Phosphate PhEur	5.7 mg
Sodium Citrate PhEur	57 mg
Menthol PhEur	1.1 mg

Action Benylin with Codeine is an antitussive preparation designed specifically to control the dry irritating cough. It combines the antitussive, antihistaminic, local anaesthetic and anticholinergic effects of Benadryl* (Diphenhydramine Hydrochloride BP) with the antitussive action of codeine phosphate.

Indications Benylin with Codeine is indicated in the treatment of persistent dry irritating cough.

Dosage and administration Oral.

Adults: Two 5 ml spoonfuls every three or four hours.

Children: 1-5 years: Half 5 ml spoonful every three or four hours.

6-12 years: One 5 ml spoonful every three or four hours.

Contra-indications, warnings, etc Known hypersensitivity to any of the active constituents. May cause drowsiness. If affected, the patient should not drive or operate machinery. Avoid alcoholic drink.

As with any other medicine, care should be taken in administration during pregnancy. Codeine may be habit forming.

Treatment of overdose: Gastric lavage in the conscious patient and intensive supportive therapy where necessary, as with cases of overdose with antihistaminic drugs.

Pharmaceutical precautions Keep container tightly closed.

Recommended diluent – Syrup BP. When diluted use within 14 days of preparation.

Legal category P.

Package quantities 2.25 litres.

Further information Nil.

Product licence number 0018/0097

BENYLIN* PAEDIATRIC

Presentation A bright red syrup. Each 5 ml contains:

Diphenhydramine Hydrochloride PhEur	7 mg
Sodium Citrate PhEur	28.5 mg
Menthol BP	0.55 mg

Action Benylin Paediatric is formulated to give comprehensive relief to the coughing child since it combines the potent antihistaminic and anticholinergic actions of Benadryl* (Diphenhydramine Hydrochloride BP) with demulcent agents: to combat the congestive symptoms that frequently accompany the cough; and reduce bronchial and nasal congestion. Benylin Paediatric contains no opiate drugs.

Indications Benylin Paediatric is indicated for the relief of cough and its congestive symptoms, and in the treatment of hay fever and other allergic conditions affecting the upper respiratory tract. It is specially formulated for children.

Dosage and administration Oral.

Children: 1-5 years: One 5 ml spoonful every three hours.

6 years and over: Two 5 ml spoonfuls every three hours.

Contra-indications, warnings, etc Known hypersensitivity to any of the active constituents.

This preparation may cause drowsiness.

Treatment of overdose: Gastric lavage in the conscious patient and intensive supportive therapy where necessary, as with cases of overdose with antihistaminic drugs.

Pharmaceutical precautions Recommended diluent – Syrup BP. When diluted use within 14 days of preparation. Keep container tightly closed.

Legal category P.

Package quantities 125 ml and 2.25 litres.

Further information Nil.

Product licence number 0018/0067.

CHLOROMYCETIN* OPHTHALMIC PREPARATIONS

Presentation Eye drops, eye ointment.

Composition: Chloromycetin Redidrops* (Ophthalmic) 0.5% (Chloramphenicol Eye Drops BP):

Chloramphenicol Ph Eur	5 mg
Boric Acid Ph Eur	15 mg
Borax Ph Eur	3 mg
Phenylmercuric Acetate BPC 1973	0.02 mg
Purified water Ph Eur	qs to 1 ml

Chloromycetin Ophthalmic Ointment (Chloramphenicol Eye Ointment BP) contains 1% chloramphenicol in a petrolatum base.

Action Chloromycetin (Chloramphenicol Ph Eur) has a wide range of antibacterial activity and is effective against virtually all bacterial pathogens known to cause diseases of the eye. It penetrates the non-inflamed eye better than any other antibiotic regardless of the mode of administration, and resistance to it is slow to develop, moderate in degree and not necessarily permanent. Clinical studies have shown that preparations of Chloromycetin for local treatment of ocular conditions are well tolerated.

Indications Treatment of bacterial conjunctivitis caused by the organisms *Escherichia coli*, *Haemophilus influenzae*, *Staphylococcus aureus*, *Streptococcus haemolyticus*, *Morax-Axenfeld* and others.

Dosage and administration The recommended dosage for adults, children and infants of all age groups is 2 drops, or a small amount of ointment to be applied to the affected eye every three hours or more frequently if required: treatment should be continued for at least 48 hours after the eye appears normal.

Contra-indications, warnings, etc Chloromycetin Ophthalmic Preparations should not be administered to patients hypersensitive to chloramphenicol.

In severe infections the topical use of chloramphenicol should be supplemented by appropriate systemic treatment. The prolonged use of antibiotics may occasionally result in overgrowth of non-susceptible organisms, including fungi. If any new infection appears during treatment the antibiotic should be discontinued and appropriate measures taken. Chloramphenicol should be reserved for use only in infections for which it is specifically indicated.

Aplastic anaemia has been reported following topical use of chloramphenicol. Whilst the hazard is a rare one, it should be borne in mind when assessing the benefits expected from the use of this compound.

Treatment of overdosage: Not applicable.

Pharmaceutical precautions *Chloromycetin Redidrops:* Store between 2–8°C. Protect from light. Contents must be used within four weeks of being dispensed.

Chloromycetin Ophthalmic Ointment 1%: Store at a temperature not exceeding 30°C. Use within one month of opening.

Legal category POM.

Package quantities *Chloromycetin Redidrops:* 5 ml and 10 ml in polythene dropper bottle.

Chloromycetin Ophthalmic Ointment 1%: Collapsible tube of 4 g.

Further information Nil

Chloromycetin Ophthalmic Ointment 1%	0018/5074

EPANUTIN* CAPSULES AND SUSPENSION

Presentation Epanutin Capsules (Phenytoin Capsules BP) contain 25 mg, 50 mg or 100 mg Phenytoin Sodium Ph Eur.

Epanutin Suspension (Phenytoin Mixture BPC 1973) contains 30 mg Phenytoin BPC 1973 in 5 ml.

Epanutin Capsules 25 mg: A white powder in a No. 4 hard gelatin capsule with a white opaque body and a purple opaque cap imprinted PARKE DAVIS. PD25

Epanutin Capsules 50 mg: A white powder in a No. 4 hard gelatin capsule with a white opaque body and a pale pink opaque cap imprinted PARKE DAVIS PD50

Epanutin Capsules 100 mg: A white powder in a No. 3 hard gelatin capsule with a white opaque body and orange cap imprinted PARKE DAVIS. PD100

Epanutin Suspension: Cherry-red suspension.

Action Anticonvulsant which appears to stabilise rather than raise the seizure threshold and prevent spread of seizure activity rather than abolish the primary focus of seizure discharge.

Indications Control of grand mal epilepsy, temporal lobe seizures and certain other convulsive states. Epanutin has also been employed in the treatment of migraine, trigeminal neuralgia and certain psychoses.

Dosage and administration *Epanutin Capsules:* Oral.

Adults: 100 mg two to four times daily before meals, with a maximum total of 600 mg a day.

Infants and children up to 3 years: The initial dose is up to 50 mg two or three times daily.

Children 4–6 years: The dosage may be increased above the infant dose.

Children 7–12 years: As for adults.

Each dose of Epanutin should be followed by at least $\frac{1}{2}$ tumblerful of water. In cases showing a tendency to nausea and a feeling of fullness of the stomach, the dose may be given with or following meals.

Epanutin Suspension: Oral.

Adults: 15 ml three times daily. Subsequent dosage should be adjusted according to the therapeutic response.

Children under 6 years: 5 ml twice daily increasing to 5 ml three or four times daily.

Children 6 years and over: As for adults.

These dosages are a guide only and the generally accepted principles of anticonvulsant treatment should be carried out, i.e. Epanutin Capsules or Suspension should be introduced in small dosage with gradual increments until control is achieved (or therapeutic blood levels reached, if facilities for estimation of these exist) or until toxic effects appear. If toxic effects do appear, the dose should be decreased, and if control is not achieved, the drug should be withdrawn gradually and an alternative anticonvulsant substituted. Maintenance of treatment should be the lowest dose of anticonvulsant consistent with control of seizures.

Contra-indications, warnings, etc Hypersensitivity to hydantoins.

There is some evidence that phenytoin may produce congenital abnormalities in the offspring of a small number of epileptic patients, therefore it should not be used as the first drug in pregnancy, especially early pregnancy, unless in the judgement of the physician the potential benefits outweigh the risk. Small quantities of phenytoin are excreted in breast milk.

If the patient has been receiving other anticonvulsants, such as phenobarbitone, the sudden withdrawal of the drugs may precipitate a series of attacks before Epanutin has been given in sufficient amounts to exercise control. This may be avoided by gradually replacing with Epanutin the anticonvulsant previously used.

During initial treatment, minor side-effects may include gastric distress, nausea, transient nervousness, weight loss, sleeplessness and a feeling of unsteadiness. Side-effects usually subside with continued use. Allergic phenomena such as polyarthropathy, fever, skin eruptions and hepatitis may occur. Eruptions usually subside upon discontinuance of therapy. Lupus erythematosus and erythema multiforme have occurred. Though mild and rarely an indication for stopping dosage, gingival hypertrophy, hirsutism and excessive motor activity are occasionally encountered in the younger age groups. Haematological disorders including megaloblastic anaemia, leucopenia, agranulocytosis, thrombocytopenia, ancytopenia and aplastic anaemia have been reported. The occasional occurrence of lymphadenopathy indicates the need to differentiate such a condition from that of lymph-gland pathology. Nystagmus in combination with diplopia and ataxia indicates that dosage should be reduced.

Phenytoin should be used with caution in the presence of liver dysfunction.

Certain drugs have been shown to elevate phenytoin plasma levels including antituberculous agents, dicoumarol anticoagulants, sulthiame, pheneturide, disulfiram, chloramphenicol, halothane, thyroid preparations and ioxazine. The levels of phenytoin are decreased by carbamazepine. The effect of phenytoin may be diminished by alcohol and altered by phenobarbitone. Phenytoin induced enzyme induction can enhance the metabolism of oral contraceptives and therefore may lead to a diminished contraceptive effect. Phenytoin may affect blood calcium and blood sugar metabolism and exanthemasone and metyrapone tests.

Treatment of overdosage: The mean lethal dose for adults is estimated to be 2-5 g. The cardinal initial symptoms are nystagmus, ataxia and dysarthria. The patient then becomes comatose, the pupils are unresponsive and hypotension occurs followed by respiratory depression and apnoea. Treatment is non-specific since there is no known antidote. First, the stomach should be emptied. If the gag reflex is absent, the airway should be supported. Oxygen, vasopressors and assisted ventilation may be necessary for central nervous system respiratory and cardiovascular depression. Total exchange transfusion has been utilised in the treatment of severe intoxication in children.

Pharmaceutical precautions Store at a temperature not exceeding 30°C.

Epanutin Suspension: Suitable diluent - Syrup BP. When diluted use within 14 days of preparation.

Legal category POM.

Package quantities Epanutin Capsules 100 mg are available in containers of 500 and 1,000.

Epanutin Capsules 50 mg and 25 mg are available in containers of 500.

Epanutin Suspension (30 mg per 5 ml) is available in bottles of 500 ml.

Further information Conventional doses of phenytoin will produce a therapeutically desirable serum level (between 10 and 20 micrograms/ml) only in a proportion of patients under treatment. Levels below 10 micrograms/ml may result in ineffective treatment, whilst it has been reported that with levels above 20 to 25 micrograms/ml toxic effects begin to appear.

The 25 mg Epanutin Capsule has been introduced because incremental doses of the drug should become progressively smaller as the serum concentration increases, since there is no linear relationship between dose and serum level - for example, an incremental dose of 50 mg may be enough to increase a serum level in a particular patient from 10 micrograms/ml to a toxic level.

Product licence numbers

Epanutin Capsules 25 mg	0018/0112

EPANUTIN* INFATABS*

Presentation Yellow, triangular, flat, chewable tablets with breaking line on one side and with a spearmint flavour. Each Infatab contains 50 mg Phenytoin BPC 1973.

Action Anticonvulsant which appears to stabilise rather than raise the seizure threshold and prevent spread of seizure activity rather than abolish the primary focus of seizure discharge.

Indications Control of grand mal epilepsy, temporal lobe seizures and certain other convulsant states.

Dosage and administration Oral - to be chewed.

Initially: Under 1 year: $\frac{1}{2}$ tablet twice daily.

1-6 years: $\frac{1}{2}$ tablet two to four times daily.

7-12 years: 1 tablet two to four times daily.

Adults: 2 tablets two to four times daily.

These dosages are a guide only and the generally accepted principles of anticonvulsant treatment should be carried out, i.e. Epanutin Infatabs should be introduced in small dosage with gradual increments until control is achieved (or therapeutic blood levels reached, if facilities for estimation of these exist) or until toxic effects appear. If toxic effects do appear, the dose should be decreased, and if control is not achieved, the drug should be withdrawn gradually and an alternative anticonvulsant substituted. Maintenance of treatment should be the lowest dose of anticonvulsant consistent with control of seizures.

Equal doses of Epanutin Infatabs and Capsules may not give rise to equivalent blood levels.

Contra-indications, warnings, etc Hypersensitivity to hydantoins.

There is some evidence that phenytoin may produce congenital abnormalities in the offspring of a small number of epileptic patients, therefore it should not be used as first drug during pregnancy, especially in early pregnancy, unless in the judgement of the physician, the

potential benefits outweigh the risks. Small quantities of phenytoin are excreted in breast milk.

If the patient has been receiving other anticonvulsants, the sudden withdrawal of the drugs may precipitate a series of seizures before Epanutin Infatabs have been given in sufficient amounts to exercise control. This may be avoided by replacing the anticonvulsant previously used gradually with Epanutin Infatabs. During initial treatment, minor side-effects may include gastric distress, nausea, transient nervousness, weight loss, sleeplessness and a feeling of unsteadiness. Side-effects usually subside with continued use. Allergic phenomena such as polyarthropathy, fever, skin eruptions and hepatitis may occur. Eruptions usually subside upon discontinuance of therapy. Lupus erythematosus and erythema multiforme have occurred. Though mild and rarely an indication for stopping dosage, gingival hypertrophy, hirsutism and excessive motor activity are occasionally encountered in the younger age groups. Haematological disorders including megaloblastic anaemia, leucopenia, agranulocytosis, thrombocytopenia, pancytopenia and aplastic anaemia have been reported. The occasional occurrence of lymphadenopathy indicates the need to differentiate such a condition from other lymph-gland pathology. Nystagmus in combination with diplopia and ataxia indicates that dosage should be reduced.

Phenytoin should be used with caution in the presence of liver dysfunction.

Certain drugs have been shown to elevate phenytoin plasma levels including anti-tuberculous agents, dicoumarol anticoagulants, sulthiame, pheneturide, disulfiram, chloramphenicol, halothane, thyroid preparations and viloxazine. The levels of phenytoin are decreased by carbamazepine. The effect of phenytoin may be diminished by alcohol and altered by phenobarbitone. Phenytoin induced enzyme induction can enhance the metabolism of oral contraceptives and therefore may lead to a diminished contraceptive effect. Phenytoin may affect blood calcium and blood sugar metabolism and dexamethasone and metyrapone tests.

Treatment of overdose: The mean lethal dose for adults is estimated to be 2-5 g. The cardinal initial symptoms are nystagmus, ataxia and dysarthria. The patient then becomes comatose, the pupils are unresponsive and hypotension occurs followed by respiratory depression and apnoea. Treatment is non-specific since there is no known antidote. First, the stomach should be emptied. If the gag reflex is absent, the airway should be supported. Oxygen, vasopressors and assisted ventilation may be necessary for central nervous system, respiratory and cardiovascular depression. Total exchange transfusion has been utilised in the treatment of severe intoxication in children.

Pharmaceutical precautions Store at a temperature not exceeding 30°C.

Legal category POM.

Package quantities Packs of 100 tablets

EPANUTIN* WITH PHENOBARBITONE CAPSULES

Presentation Capsules containing 100 mg Phenytoin

Sodium Ph Eur and 50 mg Phenobarbitone Ph Eur, white powder in a No. 3 hard gelatin capsule with white opaque body and yellow cap, imprinted PARKE-DAVIS

Action Anticonvulsant. Phenytoin appears to stabilise rather than raise the seizure threshold and prevent spread of seizure activity rather than abolish the primary focus of seizure discharge.

Indications Control of grand mal epilepsy, temporal lobe seizures and certain other convulsive states.

Dosage and administration Oral.

Adults: 1-3 capsules daily according to therapeutic response.

Children: None.

Each dose of Epanutin with Phenobarbitone should be followed by at least $\frac{1}{2}$ tumblerful of water. In case showing a tendency to nausea and a feeling of fullness of the stomach, the dose may be given with or following meals.

These dosages are a guide only and the generally accepted principles of anticonvulsant treatment should be carried out, i.e. Epanutin with Phenobarbitone Capsules should be introduced in small dosage with gradual increments until control is achieved (or therapeutic blood levels reached, if facilities for estimation of these exist) or until toxic effects appear. If toxic effects do appear, the dose should be decreased, and if control is not achieved, the drugs should be withdrawn gradually and an alternative anticonvulsant substituted. Maintenance of treatment should be the lowest dose of anticonvulsant consistent with control of seizures.

Contra-indications, warnings, etc Hypersensitivity to hydantoins or barbiturates.

There is some evidence that phenytoin and phenobarbitone may produce congenital abnormalities in the offspring of a small number of epileptic patients, therefore they should not be used as first drugs during pregnancy, especially early pregnancy, unless in the judgement of the physician, potential benefits outweigh the risks. Small quantities of phenytoin and phenobarbitone are excreted in breast milk.

If the patient has been receiving other anticonvulsants, the sudden withdrawal of the drugs may precipitate a series of attacks before Epanutin with Phenobarbitone has been given in sufficient amounts to exercise control. This may be avoided by gradually replacing with Epanutin with Phenobarbitone the anticonvulsant previously used.

During initial treatment, minor side-effects from phenytoin may include gastric distress, nausea, transient nervousness, weight loss, sleeplessness and a feeling of unsteadiness. Side-effects usually subside with continued use. Allergic phenomena such as polyarthropathy, fever, skin eruptions and hepatitis may occur. Eruptions usually subside upon discontinuance of therapy. Lupus erythematosus and erythema multiforme have occurred. Though mild and rarely an indication for stopping dosage, gingival hypertrophy, hirsutism and excessive motor activity are occasionally encountered in the younger age groups. Haematological disorders including megaloblastic anaemia, leucopenia, agranulocytosis, thrombocytopenia, pancytopenia and aplastic anaemia have been reported. The occasional occurrence of lymphadenopathy indicates the need to differentiate such a condition from other lymph-gland pathology. Nystagmus in combination with diplopia and ataxia indicates that dosage should be reduced.

Epanutin with Phenobarbitone should be used with care in patients with impaired hepatic or renal function, and is contra-indicated in patients with acute intermittent porphyria.

Phenobarbitone causes drowsiness.

Certain drugs have been shown to elevate phenytoin plasma levels including antituberculous agents, dicoumarol anticoagulants, sulthiame, pheneturide, disulfiram, chloramphenicol, halothane, thyroid preparations and iloxazine. The levels of phenytoin are decreased by carbamazepine. The effect of phenytoin may be diminished by alcohol and altered by phenobarbitone. Anticonvulsant induced enzyme induction can enhance the metabolism of oral contraceptives and therefore may lead to a diminished contraceptive effect. Phenytoin may affect blood-calcium and blood sugar metabolism and lefamethasone and metyrapone tests.

Barbiturates will increase the effects of CNS depressants, e.g. alcohol, antihistamines.

Treatment of overdosage: The mean lethal dose of phenytoin for adults is estimated to be 2–5 g. The cardinal initial symptoms are nystagmus, ataxia and dysarthria. The patient then becomes comatose, the pupils are unresponsive and hypotension occurs followed by respiratory depression and apnoea. Treatment is non-specific since there is no known antidote. First, the stomach should be emptied. If the gag reflex is absent, the airway should be supported. Oxygen, vasopressors and assisted ventilation may be necessary for central nervous system, respiratory and cardiovascular depression. Total exchange transfusion has been utilised in the treatment of severe intoxication in children. Forced alkaline diuresis and charcoal haemoperfusion may be considered to hasten the removal of phenobarbitone.

Pharmaceutical precautions Store at a temperature not exceeding 30°C.

Legal category POM.

Package quantities Epanutin with Phenobarbitone capsules are available in containers of 500.

Further information Nil.

Product licence number 0018/5105.

PANUTIN* READY MIXED PARENTERAL

Representation Epanutin Ready Mixed Parenteral Phenytoin Injection BP) contains 250 mg Phenytoin sodium Ph Eur in each 5 ml ampoule.

Action Anticonvulsant which appears to stabilise rather than raise the seizure threshold and prevent spread of seizure activity rather than abolish the primary focus of seizure discharge.

Indications Epanutin Ready Mixed Parenteral is indicated for the control of status epilepticus and other persistent convulsive disorders: for the prophylactic control of seizures in neurosurgery. It is of use in the treatment of certain cardiac arrhythmias, especially when these are digitalis induced.

Dosage and administration *Use in status epilepticus:* **Adults:** By slow intravenous injection, at a rate not exceeding 50 mg per minute, 150–250 mg, followed if necessary, after 30 minutes, by 100–150 mg. Where it is impossible to immobilise an extremity, or veins are inaccessible, the intramuscular route may be used

initially. Great care should be taken to avoid the risk of breaking the injection needle.

Children: Dosage is usually determined according to weight, in proportion to the dosage for a 150 lb (70 kg) adult.

Use in neurosurgery: 2–4 ml (100–200 mg) intramuscularly three to four times daily during the period encompassing surgery and the post-operative phase.

Use in cardiac arrhythmias: 3.5–5 mg per kg of body weight intravenously initially, repeated once if necessary. The solution should be injected slowly intravenously and at a uniform rate which should not exceed 1 ml (50 mg) per minute.

Contra-indications, warnings, etc Hypersensitivity to hydantoin. Heart block. Intra-arterial administration must be avoided in view of the high pH of the preparation.

Fatalities due to cardiac arrest, ventricular fibrillation, tonic seizures and respiratory arrest have been reported following intravenous administration of phenytoin in cases with cardiac arrhythmias. Alterations of cardiac and respiratory function can be produced by too rapid administration of the drug intravenously. Complications may occur more readily in elderly and gravely ill patients. In all cases optimal dosage of Epanutin Ready Mixed Parenteral must be determined by trial. Dosage in excess of the minimum required to prevent convulsions is not recommended. Subcutaneous or perivascular injection should be avoided because of the highly alkaline nature of the solution, which may cause local tissue damage. Solutions of Epanutin Ready Mixed Parenteral should not be added to intravenous solutions because of the precipitation of the free acid.

There is some evidence that phenytoin may produce congenital abnormalities in the offspring of a small number of epileptic patients, therefore it should not be used as first drug during pregnancy, especially early pregnancy, unless in the judgement of the physician the potential benefits outweigh the risks. Small quantities of phenytoin are excreted in breast milk.

Caution: The use of Epanutin by the intravenous route should be considered an emergency procedure. Continuous electrocardiographic monitoring is recommended. As with the administration of any potent cardiac anti-arrhythmic drug, cardiac resuscitative equipment should be available.

Treatment of overdosage: The mean lethal dose in adults is estimated to be 2–5 g. The cardinal initial symptoms are nystagmus, ataxia and dysarthria. The patient then becomes comatose, pupils unresponsive and hypotension occurs followed by respiratory depression and apnoea. Treatment is non-specific since there is no known antidote. If the gag reflex is absent, the airway should be supported. Oxygen, vasopressors and assisted ventilation may be necessary for central nervous system, respiratory and cardiovascular depression. Total exchange transfusion has been utilised in the treatment of severe intoxication in children.

Pharmaceutical precautions Store at a temperature not exceeding 25°C. Protect from light. The product should not be used if a precipitate or haziness develops in the solution in the ampoule. Epanutin Ready Mixed Parenteral should not be added to intravenous infusion fluids because of precipitation of the acid.

Legal category POM.

Package quantities 10 × 5 ml ampoules.

Product licence number 0018/0070.

LOESTRIN* 20

Presentation A pale blue-grey film-coated tablet. Each tablet contains Norethisterone Acetate BP 1 mg and Ethinyloestradiol Ph Eur 0.02 mg.

Action Loestrin achieves contraceptive effect primarily by inhibition of ovulation through gonadotrophin suppression. It is possible that other sites of action such as changes in cervical mucus and in the endometrium may contribute to the efficacy of combined oral contraceptives.

Indications Control of conception.

Dosage and administration *Oral:* One Loestrin tablet should be taken daily for three weeks, starting on the fifth day of menstrual bleeding, and then an interval of one week allowed before commencing the second course of tablets. In the first cycle only, it is advisable to use another method of contraception for the first 14 days in addition to taking the tablets. Second and subsequent courses should be taken for three weeks with one week without tablets between courses. Thus each new course of tablets is always started on the same day of the week. It is important that the tablets are taken as directed. Tablets should be taken without regard to menstrual bleeding except in the initial cycle.

If a tablet is not taken at the usual time, it must be taken within the next 12 hours. If the delay exceeds 12 hours the course should be continued by taking the tablets in the pack at their proper times and leaving the missed tablet(s). Additional contraceptive methods should be used until the next withdrawal bleed.

Vomiting and/or diarrhoea may reduce the effectiveness of the pill. If this occurs extra contraceptive measures should be taken for the rest of the cycle.

It has been suggested that certain drugs may produce increased metabolism of oral contraceptive steroids. Patients receiving additional drugs, including phenobarbitone, phenytoin and some antibiotics, might be advised to use non-hormonal additional methods of contraception for the rest of the cycle.

Post-partum: Oral contraception is usually started as soon as spontaneous menstruation has resumed after childbirth. However, oral contraception can be started within 7–12 days of a vaginal delivery, provided that the patient is ambulant and there are no puerperal complications. If medication is started within 12 days of delivery, additional contraceptive precautions are unnecessary. After a first trimester abortion, oral contraceptives can normally be started immediately.

Children: None.

Contra-indications, warnings, etc

Contra-indications: Thromboembolic disorders, or a past history of these conditions; sickle cell anaemia; known or suspected disorders of lipid metabolism; markedly impaired liver function; known or suspected carcinoma of the breast; known or suspected oestrogen dependent neoplasms; undiagnosed abnormal vaginal bleeding. Loestrin should not be given during pregnancy, or to patients with a history of severe pruritis during pregnancy or of herpes of pregnancy. Loestrin should not be given

to patients with a history of otosclerosis, idiopathic jaundice; Dubin-Johnson or Roter syndromes or an significant liver disease.

Warnings: The use of oral contraceptives has been shown to be associated with an increased risk of thromboembolic disorders. The physician should be alert to the earliest manifestations of these disorders, (thrombophlebitis, cerebrovascular disorders, pulmonary embolism, and retinal thrombosis). Should any of these occur or be suspected, Loestrin should be discontinued immediately.

Certain factors may predispose to the development of thrombosis, e.g. smoking, obesity, age, the presence of varicose veins, cardiovascular disease, diabetes and migraine. The suitability of combined oral contraceptive for patients with any of these conditions should be discussed with the patient before a final decision is taken.

The risk of arterial thrombosis associated with combined oral contraceptives increases with age, and the risk is aggravated by cigarette smoking. The use of combined oral contraceptives by women in the older age group, especially those who are cigarette smokers should therefore be discouraged, and alternative methods advised.

Very rarely, hepatic tumours have been reported in users of combined oral contraceptives, generally for a protracted period of time. A hepatic tumour should be considered in the differential diagnosis when upper abdominal pain, enlarged liver or signs of intra-abdominal haemorrhage occur.

Medication should be discontinued pending examination if there is a sudden onset of proptosis, diplopia or migraine.

Patients with a history of depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree.

Since the safety of Loestrin in pregnancy has not been demonstrated, it is recommended that for any patient who has missed a period, the absence of pregnancy should be established before continuing the contraceptive regimen.

Combined oral contraceptives should be stopped at least six weeks before elective surgery and during immobilisation, e.g. after accidents etc.

Loestrin should be discontinued if the patient becomes jaundiced or has a significant rise in blood pressure.

Precautions: The pre-treatment and periodic physical examination should include special reference to breast and pelvic organs, including Papanicolaou smear since oestrogens have been known to produce tumours, some of them malignant in five species of subprimate animals.

Oestrogen-progestogen preparations should be used with caution in patients with a history of hypertension. Some women experience an increase in blood pressure following administration of contraceptive steroids. Pregnancy should be excluded before starting treatment.

Because these agents may cause some degree of fluid retention, patients with conditions which might be influenced by this such as epilepsy, migraine, asthma and cardiac or renal dysfunction, should be carefully observed.

A decrease in glucose tolerance has been observed in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving Loestrin.

Under the influence of oestrogen-progestogen prep-

rations, pre-existing uterine fibroid myoma may increase in size.

The following conditions also require careful consideration: multiple sclerosis, porphyria, tetany, disturbed liver function, gallstones, cardiovascular disease, renal disease, chloasma, the wearing of contact lenses or any disease that is prone to worsen during pregnancy. The deterioration or first appearance of any of these conditions may indicate that the oral contraceptive should be stopped.

Loestrin may mask the onset of the climacteric.

The following laboratory results may be altered by the use of oral contraceptives: hepatic function (increased urobilinogen retention and other tests); thyroid function (thyroid-binding globulin, T3, T4 serum levels); haematological tests (increase in prothrombin factors II, VIII, IX, and X; decreased antithrombin; increased adrenalin-induced platelet aggregation); measurement of pregnanediol excretion (reduced). Therefore, if such tests are abnormal in a patient taking Loestrin, it is recommended that they be repeated after Loestrin has been withdrawn for two months.

The pathologist should be advised of the administration of Loestrin when relevant specimens are submitted.

Any possible influence of prolonged administration of Loestrin on pituitary, ovarian, adrenal, hepatic and uterine functions is unknown at present.

A small fraction of the hormonal agents in oral contraceptives have been identified in the milk of mothers receiving these drugs. The long range effect to the nursing infant is at present unknown.

Adverse effects: The following adverse effects which have been reported in patients receiving oral contraceptives are believed to be drug-related.

Nausea, vomiting, gastro-intestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhoea during and after treatment, oedema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight, cervical erosion and changes in cervical secretion, suppression of lactation when given immediately post-partum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure, depression, and thromboembolic disorders.

Although the following adverse effects have been reported in women taking oral contraceptives, an association has been neither confirmed nor refuted: prolonged amenorrhoea after discontinuing oral contraceptives, pre-menstrual like syndrome, headache, nervousness, dizziness, fatigue, cataract, backache, hirsutism, loss of scalp hair, erythema multiforme, erythema nodosum, haemorrhagic eruption and itching.

In most women the menstrual flow is reduced and occasionally may be missed altogether. This reduced flow is not normally indicative of pregnancy, particularly if the tablets have been taken correctly, but pregnancy should be ruled out before a new course of tablets is started.

Breakthrough bleeding happens more often in the first two or three cycles after starting the tablets. The patient should continue taking the tablets according to the schedule if breakthrough bleeding occurs. Probably it will amount to no more than spotting and will not last more than a day or two. If breakthrough bleeding is experienced after the third cycle, the patient should consult her physician.

Treatment of overdosage: The usual effects in children are nausea, and drowsiness. Slight vaginal bleeding

occasionally occurs in girls. In view of the low toxicity following overdosage with oral contraceptives, it is suggested that treatment should be conservative.

Clinical discussion: In view of the reports of thromboembolism following the use of oral contraceptives, the trend in prescribing has been towards avoiding formulations with high oestrogen content. Parke-Davis have developed this low dose formulation in which the ethinylloestradiol content is only 20 mcg in the expectation that the dosage may be less likely to give rise to thromboembolic disorders. Obviously it may take many years to establish this hypothesis.

Pharmaceutical precautions No special storage precautions.

Legal category POM.

Package quantities Available in packs of 21 tablets.

Further information Nil.

Product licence number 0018/0086.

PONSTAN® Capsules

(Mefenamic Acid Capsules BP)

PONSTAN® Paediatric Suspension

(Mefenamic Acid Suspension 50 mg/5 ml)

Presentation *Capsules:* An off-white powder in a No. 1 hard gelatin capsule with an ivory opaque body and aqua-blue opaque cap. Each capsule contains Mefenamic Acid BP 250 mg.

Paediatric Suspension: An off-white suspension, with a typical aroma and taste. Each 5 ml suspension contains Mefenamic Acid BP 50 mg.

Action Mefenamic acid is an analgesic with anti-inflammatory properties and a demonstrable antipyretic effect. It has also been shown to inhibit prostaglandin activity.

Indications 1. For the relief of mild to moderate pain including muscular, traumatic and dental pain, headaches of most aetiology, post operative and post partum pain; pyrexia in children.

2. For the relief of mild to moderate pain in rheumatoid arthritis (including Still's Disease) and osteoarthritis.

3. Menorrhagia due to dysfunctional causes and presence of an IUD when other pelvic pathology has been ruled out.

Dosage and administration Oral.

Adults: 2 capsules (500 mg) three times daily.

In menorrhagia to be administered on the first day of excessive bleeding and continued according to the judgement of the physician.

Children: It is recommended that children under 12 years of age should be given Ponstan Paediatric Suspension (50 mg/5 ml) in the following dosage regime.

Infants over 6 months – 25 mg/kg of body weight daily in divided doses, or

6 months–1 year – one 5 ml spoonful.

2 years–4 years – two 5 ml spoonfuls.

5 years–8 years – three 5 ml spoonfuls.

9 years–12 years – four 5 ml spoonfuls.

Dose may be repeated as necessary, up to three times daily.

Apart from the treatment of Still's Disease, therapy should not be continued for longer than seven days in children.

Contra-indications, warnings, etc Mefenamic acid is contra-indicated in inflammatory bowel disease and in patients suffering from peptic and/or intestinal ulceration, and in patients with renal or hepatic impairment.

Precautions: Safety in pregnancy has not been established. In patients suffering from dehydration and renal disease, particularly the elderly. Concurrent therapy with other plasma protein binding drugs may necessitate a modification in dosage. In the case of anticoagulants the dose of the anticoagulant may need to be reduced.

In menorrhagia lack of response should alert the physician to investigate other causes.

Warnings and adverse effects: Diarrhoea occasionally occurs following usual analgesic dosage of mefenamic acid and has been reported to have occurred within 24 hours of starting treatment. If diarrhoea occurs, the medication should be discontinued immediately. The patient so affected is usually henceforth unable to tolerate the drug without recurrence of diarrhoea.

Skin rashes have been observed following the administration of mefenamic acid and occurrence of a rash is a definite indication to withdraw medication.

As with other prostaglandin inhibitors allergic glomerulonephritis has occurred occasionally: non-oliguric renal failure has been reported on a few occasions in elderly patients with dehydration usually from diarrhoea. It has been suggested that the recovery is more rapid and complete than with other forms of analgesic induced renal impairment.

Rarely, thrombocytopenia has been reported with mefenamic acid.

In some cases reversible haemolytic anaemia has occurred. Temporary lowering of the white blood cell count which may have been due to mefenamic acid has been reported. Blood studies should therefore be carried out during long-term administration.

Bronchospasm may be precipitated in patients suffering from, or with a previous history of, bronchial asthma or allergic disease. Patients on prolonged therapy should also be kept under surveillance with particular attention to liver dysfunction. Should this appear it is an indication to discontinue therapy.

Drowsiness and dizziness have rarely been reported.

Note: A positive reaction in certain tests for bile in the urine of patients receiving mefenamic acid has been demonstrated to be due to the presence of the drug and its metabolites and not to the presence of bile.

Treatment of overdosage: Gastric lavage in the conscious patient and intensive supportive therapy where necessary. Activated charcoal has been shown to be a powerful adsorbent for mefenamic acid and its metabolites. Studies in experimental animals showed that a 5 to 1 ratio of charcoal to mefenamic acid resulted in considerable suppression of absorption of the drug.

Pharmaceutical precautions Store at a temperature not exceeding 30°C. Recommended diluent for Suspension – Syrup BP. When diluted use within 14 days of preparation.

Legal category POM.

Package quantities *Capsules:* Available in packs of 100 and 500.

Suspension: Available in packs of 125 ml.

Further information Nil.

VIRA-A* ▼

Presentation An ophthalmic ointment.

Composition: Vira-A (Vidarabine) Ophthalmic Ointment contains: Vidarabine (9- β -D-arabinofuranosyladenine) 3% in a sterile, inert, petrolatum base.

Action Vira-A is a purine nucleoside which possesses antiviral activity. Vira-A possesses virostatic activity against the DNA family of viruses including herpes simplex (types I and II), varicella, vaccinia, and cytomegalovirus in both tissue culture and experimental animal infections.

Vira-A is rapidly metabolised to arabinosyl-hypoxanthine (Ara-Hx), the principal metabolite. Ara-Hx also possesses antiviral activity but it is significantly less than that of the parent compound. Following topical ocular administration in humans, trace amounts of both Vira-A and Ara-Hx can be detected in the aqueous humour only if the cornea is severely defective. If the cornea is intact, only trace amounts of Ara-Hx can be recovered from the aqueous humour.

Systemic absorption of Vira-A should not occur following ocular administration and swallowing tears from the lacrimal duct. In laboratory animals, Vira-A is rapidly deaminated in the gastro-intestinal tract to Ara-Hx. Vira-A interferes with corneal wound healing less than other forms of antiviral ocular chemotherapy such as idoxuridine.

Indications Vira-A Ophthalmic Ointment is indicated for the treatment of herpes keratoconjunctivitis manifested by dendritic keratitis or geographic corneal ulcers. The drug is effective against both fresh corneal lesions and those which have not responded to idoxuridine. Vira-A is also indicated in patients who have developed toxic or allergic reactions to idoxuridine. The diagnosis is established by finding the typical dendritic or geographic lesions on slit-lamp examination. Generally, an average of seven days' continuous therapy is required to achieve corneal re-epithelialisation of previously untreated lesions. Approximately 90% of treated eyes will re-epithelialise by the end of three weeks' therapy. Lesions which have not healed previously on idoxuridine require an average of 11 days to re-epithelialise. Approximately

75% of patients with idoxuridine-refractory lesions will heal by the end of four weeks of Vira-A therapy. Continuation of therapy for an additional seven days after corneal re-epithelialisation is recommended to prevent relapses of the infection.

Vira-A is less effective against stromal keratitis and uveitis as compared to epithelial disease secondary to the herpes virus.

Vira-A is not effective against RNA-virus and adenoviral ocular infections. It is also not effective against bacterial infections of the cornea or non-viral ulcers such as trophic or disciform keratitis.

Dosage The proper dose is to extrude one half inch of the ointment into the conjunctival sac five times daily until corneal re-epithelialisation has occurred. Treatment may then be continued at a reduced frequency, such as twice daily, for an additional seven days.

Contra-indications, warnings, etc Vira-A Ophthalmic Ointment is contra-indicated in patients who develop intolerance to it. The possibility of development of viral resistance to vidarabine cannot be ruled out. If there is no response after seven days' treatment, other forms of therapy should be considered.

Precautions: The diagnosis of herpes keratoconjunctivitis should be established clinically prior to prescribing Vira-A.

Vira-A parenterally is teratogenic in rats and mice. Typically, 10% Vira-A ointment applied to 10% of the body surface of rabbits during organogenesis induced foetal abnormalities. When 10% Vira-A ointment was applied to 2% to 3% of the body surface of rabbits, no foetal abnormalities were found. This dose greatly exceeds the total recommended human dose. Since a risk of producing foetal damage is present if Vira-A is administered to pregnant women, it should be used in women who are or may become pregnant only when it is clearly needed and the anticipated benefit to the patient outweighs this potential risk to the foetus.

It is not known whether Vira-A is secreted in human milk. As a general rule, nursing should not be undertaken while a patient is under treatment since many drugs are excreted in human milk. Patients should be forewarned that Vira-A, like any ophthalmic ointment, may produce a temporary visual haze.

Side-effects: Lacrimation, foreign body sensation, conjunctival injection, burning, irritation, superficial punctate keratitis, pain, photophobia, punctal occlusion, and sensitivity have been reported. The following have also been reported but appear disease-related: uveitis, stromal oedema, secondary glaucoma, trophic defects, corneal vascularisation, and hyphaemia.

Treatment of overdose: Acute massive overdose by oral ingestion of the ophthalmic ointment has not occurred. However, the rapid deamination to arabinosyl-hypoxanthine should preclude any serious consequences. The oral LD₅₀ for pure Vira-A is greater than 5,020 mg/kg in mice and rats. Thus, no untoward effects should result from ingestion of the entire contents of a tube (105 mg).

Ocular overdose is unlikely because any excess is quickly expelled from the conjunctival sac. Too frequent administration should be avoided.

Pharmaceutical precautions Store at a temperature not exceeding 30°C.

Legal category POM.

Package quantities Available in tubes of 3.5 g.

Further information Nil.

Product licence number 0018/0072.

VIRA-A* PARENTERAL ▼

Presentation An antiviral drug for intravenous administration only.

Composition: Vira-A (ara-A, vidarabine, adenine arabinoside) is a white crystalline solid with the empirical formula: $C_{10}H_{13}N_5O_4H_2O$. The molecular weight is 285.2; the solubility is 0.45 mg/ml at 25°C; and the melting point ranges from 260° to 270°C. The chemical name is 9-β-D-arabinofuranosyladenine.

Each ml of suspension contains 200 mg of vidarabine monohydrate equivalent to 187.4 mg of vidarabine. Each millilitre contains Pheneride* (benzethonium chloride), not more than 0.1 mg, as a preservative; disodium hydrogen phosphate, 0.957 mg, and sodium dihydrogen phosphate, 4.138 mg, as buffering agents. Hydrochloric acid may have been added to adjust pH.

Uses **Action:** Vira-A is a purine nucleoside obtained from fermentation cultures of *Streptomyces antibioticus*. Vira-A possesses *in vitro* and *in vivo* antiviral activity against herpes simplex types 1 and 2, varicella-zoster, and vaccinia viruses.

The antiviral mechanism of action has not yet been established. Vira-A appears to interfere with the early steps of viral DNA synthesis. Vira-A is rapidly deaminated to arabinosylhypoxanthine (Ara-Hx), the principal metabolite. Ara-Hx also possesses *in vitro* antiviral activity but this activity is significantly less than Vira-A.

Following IV administration, Vira-A is rapidly distributed into tissues and metabolised into Ara-Hx, resulting in low plasma levels of the parent compound. The Ara-Hx plasma levels reflect the rate of infusion, showing no accumulation with time. The mean half-life is 3.3 hours. Excretion is principally via the kidneys. Urinary excretion is constant over 24 hours. Forty-one to 53% of the daily dosage is recovered in the urine as Ara-Hx.

Indications and Usage: Varicella-zoster (herpes-zoster) infection: Vira-A is indicated in the treatment of varicella-zoster infections in the immunosuppressed patient, either localised or disseminated, and chickenpox in the immunosuppressed or immunocompromised patient. These infections are diagnosed by the typical clinical appearance. To be effective, Vira-A therapy should be initiated within six days of the onset of the disease, when new lesions are forming. The recommended dosage is 10 mg/kg/day intravenously for at least five days. Vira-A does not inhibit the rate of lesion crusting and scabbing.

Vira-A should only be administered to patients with serious varicella-zoster infections where the benefits clearly outweigh the risks.

Vira-A is not effective against RNA viral or adenoviral infections. It is also not effective against bacterial or fungal infections. There is no clinical data to indicate efficacy against cytomegalovirus, vaccinia, or variola infections.

Dosage and administration Important – the contents of the vial must be diluted prior to administration.

Method of Preparation: Each vial contains 200 mg of Vira-A per ml of suspension. The solubility of Vira-A in intravenous infusion fluids is limited. Each one mg of Vira-A requires 2.22 ml of intravenous infusion fluid for complete solubilisation. Therefore, each one litre of

intravenous infusion fluid will solubilise a maximum of 450 mg of Vira-A.

The following intravenous infusion fluids have been evaluated as being compatible with Vira-A Parenteral: 5% Dextrose Injection, 5% Dextrose and 0.33% Sodium Chloride Injection, 5% Dextrose and 0.45% Sodium Chloride Injection, 5% Dextrose and 0.9% Sodium Chloride Injection, Lactated Ringers Injection.

Vira-A has been shown to be pharmaceutically compatible with ampicillin, gentamicin and chloramphenicol.

Prepare the Vira-A solution for intravenous administration by aseptically transferring the proper dose of Vira-A into an appropriate intravenous infusion fluid. Shake the Vira-A vial well to obtain a homogeneous suspension before measuring and transferring. The intravenous infusion fluid used to prepare the Vira-A solution may be prewarmed to 35° to 40°C (95° to 100°F) to facilitate dissolution of the drug following its transference. Depending on the dose to be given, more than one litre of intravenous infusion fluid may be required. Thoroughly agitate the prepared mixture until *completely* clear. Complete dissolution of the drug, as indicated by a completely clear solution, is ascertained by careful visual inspection. Final filtration with an in-line membrane filter (0.45 µ or smaller) is recommended.

Once in solution, the drug has been found to be chemically stable at room temperature (below 86°F) for at least two weeks. However, as with all intravenous mixtures dilution should be made just prior to administration. Subsequent agitation, shaking, or inversion of the bottle is unnecessary once the drug is completely in solution.

Dosage: Chickenpox and localised or disseminated varicella-zoster - 10 mg/kg/day for at least five days.

Administration: Using aseptic technique, slowly infuse the total daily dose by intravenous infusion (prepared as discussed above) at a constant rate over a 12- to 24-hour period.

Rapid or bolus injections must be avoided.

Contra-indications, warnings, etc Vira-A is contra-indicated in patients who develop intolerance to it.

Vira-A must not be administered by the intramuscular or subcutaneous route due to the low solubility and poor absorption.

Precautions: Patients with impaired kidney function, such as following renal transplant, may have a slower rate of renal excretion of Ara-Hx. Therefore, the dosage of Vira-A may need to be adjusted according to the severity of impairment.

The volume of intravenous fluids necessary requires special care when administering Vira-A to patients susceptible to fluid overloading or cerebral oedema. Examples are patients with CNS infections and impaired renal function.

A platelet count and complete blood count are recommended during Vira-A administration since haemoglobin, haematocrit, white blood cells, and platelets may be depressed during therapy.

Because Vira-A is virostatic, some degree of immunocompetence must be present in order to achieve clinical response.

Usage in Pregnancy: Vira-A given parenterally is teratogenic in rats and rabbits.

Dosages of 5 mg/kg or higher given intramuscularly to pregnant rabbits during organogenesis induced foetal abnormalities. Dosages of 3 mg/kg or less did not induce teratogenic changes in pregnant rabbits. Vira-A doses

ranging from 30 to 250 mg/kg were given intramuscularly to pregnant rats during organogenesis; signs of maternal toxicity were induced at dosages of 100 mg/kg or higher and frank foetal abnormalities were found at dosages of 150 to 250 mg/kg.

A safe dose for the human embryo or foetus has not been established. Consequently, Vira-A should be used in pregnant patients only for life-threatening illnesses where the possible benefits to be derived outweigh the potential risks involved.

It is not known whether Vira-A is excreted in human milk. As a general rule, nursing should not be undertaken while a patient is under treatment because many drugs are excreted in human milk. If Vira-A is present in breast milk, it is unlikely that nursing infants would absorb appreciable amounts of drug because Vira-A is rapidly deaminated in the gastrointestinal tract.

Side-Effects: The principal side effects involve the gastrointestinal tract: anorexia, nausea, vomiting, and diarrhoea. In controlled and uncontrolled studies, the incidence of anorexia, nausea, vomiting, and/or diarrhoea was 14% in a dosage range of 10 to 15 mg/kg/day. These reactions are mild to moderate and seldom require termination of Vira-A.

CNS disturbances have been occasionally reported at therapeutic dosages. These are: tremor (1.8%), dizziness, hallucinations, confusion, psychosis, and ataxia.

Haematological clinical laboratory changes noted in controlled and uncontrolled studies were, a decrease in haemoglobin or haematocrit (16.5%), white blood cell count (6.8%), and platelet count (6.9%). SGOT elevations were observed in 6.6%. Other changes occasionally observed were decreases in reticulocyte count and elevated bilirubin.

Other symptoms reported were: weight loss, malaise, pruritus, rash, haematemesis, and pain at injection site.

Treatment of overdose: Acute massive overdose of the intravenous form has not been reported. Acute water overloading would pose a greater threat to the patient than Vira-A, due to its low solubility. Dosages of Vira-A two to three times the antiviral dosages can produce haematopoietic depression, principally thrombocytopenia. If a massive overdose of the intravenous form occurs, haematological, liver, and renal functions should be observed.

Acute massive oral ingestion should not be toxic because drug absorption from the gastrointestinal tract is minimal. The oral LD₅₀ for Vira-A is greater than 5,020 mg/kg in mice and rats.

Pharmaceutical precautions Store in a cool place, below 30°C (86°F). Protect from freezing. Shake well before diluting.

Legal category POM.

Package quantities Vials of 5 ml containing 200 mg/ml vidarabine monohydrate in the form of a sterile suspension. 10 × 5 ml vials per pack.

Further information Nil.

Product licence number 0018/0073.

VI-SIBLIN*

Presentation Brown Granules. Ispaghula Husks BP (obtained from *Plantago ovata*) 66.0%.

Action Plantago absorbs and retains 30 times its own volume of water and is therefore used as a bulk laxative.

Indications For the treatment of chronic constipation.

Dosage and administration Oral.

Adults: Two 5 ml spoonfuls with a glassful of water one or more times daily.

Children: None.

Contra-indications, warnings, etc Intestinal obstruction has been reported after the administration of bulk-forming agents. Patients who have difficulty swallowing should be warned not to take these preparations dry, and generous quantities of water should accompany the administration.

Treatment of overdose: None.

Pharmaceutical precautions No special storage precautions.

Legal category GSL.

Package quantities Available in packs containing 250 g.

Further information Nil.

Product licence number 0018/5063.

ZARONTIN*

Presentation Zarontin Syrup (Ethosuximide Elixir BP) is a clear red, raspberry-flavoured syrup. Each 5 ml contains Ethosuximide BP 250 mg.

Zarontin Capsules (Ethosuximide Capsules BP) are orange, 8 mm, oblong soft gelatin capsules containing a clear liquid and printed 'P-D' in ivory ink. Each capsule contains Ethosuximide BP 250 mg.

Action Ethosuximide suppresses the paroxysmal spike and wave pattern common to petit mal seizures. The frequency of epileptiform attacks is reduced, apparently by depression of the motor cortex and elevation of the threshold of the central nervous system to convulsive stimuli. Compared with other succinimide anticonvulsants, ethosuximide is more specific for pure petit mal.

Indications Primarily useful in petit mal epilepsy. When grand mal and other forms of epilepsy co-exist with petit mal, Zarontin may be administered in combination with other anticonvulsants such as phenobarbitone, Epanutin* (Phenytoin Sodium Ph Eur) and primidone.

Dosage and administration Oral.

Adults and children over 6 years: initially 2 capsules or two 5 ml spoonfuls daily and adjusted thereafter to the patient's needs; daily dosage should be increased by small increments, for example, by 1 capsule or 5 ml every four to seven days, until control is achieved with minimal side-effects; although 4–6 capsules or 20–30 ml daily in divided doses often produce control of seizures, 7–8 capsules or 35–40 ml daily is not an unusual requirement.

Children and infants under 6 years: The initial dose is 5 ml daily which is adjusted by small increments until control is achieved with minimal side-effects.

Contra-indications, warnings, etc Hypersensitivity to succinimides.

There is some evidence that the succinimides may produce congenital abnormalities in the offspring of a small number of epileptic patients, and therefore they should only be used in pregnancy if in the judgement of

the physician the potential benefits outweigh the risk. Ethosuximide may be excreted in breast milk. Zaronitin should be used with caution in patients with impaired hepatic or renal function.

Mild side-effects, which are usually transient, may occur initially. These include apathy, drowsiness, depression, mild euphoria, headache, ataxia, dizziness, anorexia, gastric upset, nausea and vomiting. Psychotic states thought to be induced or exacerbated by anticonvulsant therapy have been reported. Skin rashes have been seen in a few patients. Haematological reactions to ethosuximide appear to be uncommon. Cases of leucopenia, agranulocytosis and aplastic anaemia have been reported. The extent to which ethosuximide is implicated in these reactions is yet to be determined. Monocytosis, leucocytosis and transitory mild eosinophilia have also been noted. In most cases of leucopenia, the blood picture has been restored to normal on reduction of the dosage or discontinuation of the drug. Where leucopenia has occurred with other drugs, the polymorph count has in some cases increased steadily after starting treatment with ethosuximide and discontinuing previous medication. If the patient has been receiving other anticonvulsants the sudden withdrawal of the drugs may precipitate a series of attacks before Zaronitin has been given in sufficient amounts to exercise control. This may

be avoided by gradually replacing with Zaronitin the anticonvulsant previously used.

Treatment of overdosage: If less than 2 g have been taken, fluids should be given by mouth. If a larger dose has been taken the stomach should be emptied, respiration maintained and any other symptoms treated accordingly.

Pharmaceutical precautions *Capsules:* Store at a temperature not exceeding 30°C.

Syrup: Store at a temperature not exceeding 25°C.

Recommended diluent – Syrup BP. When diluted use within 14 days of preparation.

Legal category POM.

Package quantities *Capsules 250 mg:* 50 and 500.
Syrup: 250 ml.

Further information Nil.

ALEXAN* INJECTABLE SOLUTION ▼

Presentation Alexan (cytarabine) is available as an isotonic solution in ampoules ready for injection. Ampoules contain either 2 ml or 5 ml of a solution of 20 mg/ml cytarabine.

Uses Alexan is a cytostatic agent for induction of clinical remission and/or maintenance therapy in patients with:

Acute myeloid leukaemia
Acute non-lymphoblastic leukaemias
Acute lymphoblastic leukaemias
Blast crises of chronic myeloid leukaemia
Diffuse histiocytic lymphomas (non Hodgkin's lymphomas of high malignancy)

Dosage and administration Alexan is administered by continuous intravenous infusion, intravenous injection, intrathecal injection, intramuscular or subcutaneous injection. Due to the short half-life of cytarabine, use of a rapid i.v. injection will result, in most patients, in a plasma concentration below the minimal therapeutic level in less than one hour. If it is desirable to give a rapid i.v. injection then it is necessary to divide the daily recommended dosage into two or more administrations at equal time intervals.

To prepare an infusion solution, Alexan can be added to physiological saline or 5% aqueous glucose.

Continuous infusions have ranged from 8–12 hours to 120–168 hours. In comparison with single i.v. injections, continuous infusions of the same dosage show more pronounced side effects on the gastrointestinal tract. Intrathecal, lumbar or intraventricular administration of Alexan can be carried out with the original solution. It is recommended that 5–8 ml of cerebrospinal fluid (CSF) be drawn up, mixed with the injection solution in the syringe and slowly re-injected. Systemic toxicity is not to be expected using this route of administration.

Intramuscular and subcutaneous injections are usually only used in maintenance therapy. Intra-cutaneous injections should be avoided due to the risk of oedema.

Effective cytotoxic plasma levels may be expected to lie in the range 0.01–0.15 mcg/ml.

The dosage required should be as exact as possible for each individual and is best calculated according to body surface area. Unless otherwise indicated in special combinations Alexan should be used in the following doses:

Remission Induction Therapy:

Acute leukaemias: 100–200 mg/m²/day or 3–6 mg/kg/day

Current medical practice recommends 100 mg/m² twice daily when rapid intravenous injection is used. However, when continuous infusion is employed 100 mg/m²/day is recommended as a starting dose. The duration will depend on clinical and morphological (bone marrow) findings.

Either Treat the patient for up to seven days and allow 7–14 days treatment free to allow the bone marrow to recover before applying consolidation cycles (often of reduced duration of treatment) until remission or toxicity occurs.

or Continue to treat the patient until the appearance of bone marrow hypoplasia which may be considered a tolerance limit. Before repeating the therapy cycle (often of reduced duration) a treatment free period of at least 14 days should elapse or until the bone marrow has recovered. For remission induction therapy patients should be supervised in a centre with laboratory and supportive resources sufficient to monitor drug tolerance and protect and maintain a patient compromised by drug toxicity.

Remission Maintenance: Leukaemias: 75–100 mg/m²/day or 1.5–3 mg/kg/day for five consecutive days once a month or one day each week. CNS leukaemias: 10–30 mg/m² three times weekly intrathecally. Lymphomas: These conditions are normally treated with a suitable combination of agents.

Contra-indications, warnings, etc

Contra-indications: Patients who already have bone marrow suppression should be excluded from treatment with Alexan unless the clinician considers such a course vital in the patient's interest.

Warnings: Hyperuricaemic prophylaxis is an absolute requirement, particularly in patients with high blast counts with acute monoblastic leukaemia or with large tumour masses. The clinician should monitor the patient's blood uric acid level and be prepared to use such supportive and pharmacological measures as might be necessary to control this problem. Because of the possible teratogenic effect of cytarabine on male and female germ cells adequate conception control should be established during, and for a sufficient period after, treatment.

To minimise the risks associated with remission induction therapy (granulocytopenia and associated infection, haemorrhage secondary to thrombocytopenia) Alexan should only be used in centres where adequate supportive therapy is available. Cytarabine has also been reported to cause chromosome breaks in human leucocytes in vitro. It inhibits DNA synthesis in mammalian cell cultures. These factors should be considered in long term administration.

Use in Pregnancy: Alexan is known to be teratogenic in some animal species and should be used in women who are or who may become pregnant only after due consideration of the benefit/risk potential.

The use of Alexan in nursing mothers is not recommended.

Precautions: Alexan is a potent bone marrow suppressant. During induction therapy patients should be closely supervised and leucocyte and platelet counts performed daily. Remission maintenance may be carried out under

out-patient conditions but effects on the blood picture and bone marrow must be carefully monitored. If the platelet count falls below 50,000/cu.mm. or the leucocyte count falls below 1,000/cu.mm. suspension or modification of therapy should be considered. The blood count may continue to fall following discontinuation of Alexan. Treatment may be recommenced if indicated, when bone marrow recovery is confirmed by bone marrow biopsy.

Haemopoietic, renal and hepatic function should be regularly monitored.

Side Effects: With high dosage continuous infusion (more than 200 mg/m²/day) over 5–7 days the gastrointestinal complications are more pronounced and can exceptionally lead to paralytic ileus.

The following may also occur during treatment with Alexan: bone marrow suppression (such as thrombocytopenia, leucopenia, anaemia), megaloblastosis, immunosuppression, nausea, vomiting, diarrhoea, oral inflammation or ulceration, fever, pneumonia, anorexia, hepatic dysfunction.

Pharmaceutical precautions Store below 15°C.

Legal category POM.

Package quantities Alexan is a solution (20 mg/ml) ready prepared for use.

It is packed as:

2 ml ampoule (40 mg cytarabine) in packs of 10.
5 ml ampoule (100 mg cytarabine) in packs of 10.

Further information There is extensive literature available on the effectiveness of cytarabine both alone and in combination with other agents in the treatment of conditions for which it is indicated.

Product licence number 0057/0190.

ATARAX*

Presentation Atarax brand of hydroxyzine hydrochloride is available as:

10 mg sugar-coated tablets, coloured orange and coded on one side with 'Pfizer'.

25 mg sugar-coated tablets, coloured green and coded on one side with 'Pfizer'.

Syrup 10 mg/5 ml clear, flavoured with sugar, peppermint, spearmint and caramel.

Uses **Actions:** Atarax is rapidly absorbed from the gastro-intestinal tract and its effects are usually noted within 15 to 30 minutes after oral administration.

Atarax is unrelated chemically to phenothiazine, reserpine and meprobamate. Atarax has demonstrated its clinical effectiveness in the management of neuroses and emotional disturbances manifested by anxiety, tension, agitation, apprehension or confusion.

Atarax has been shown clinically to be a rapid-acting true ataractic with a wide margin of safety. It induces a calming effect in anxious, tense, psychoneurotic adults and also in anxious, hyperkinetic children without impairing mental alertness. It is not a cortical depressant,

but its action may be due to a suppression of activity in certain key regions of the subcortical area of the central nervous system.

Primary skeletal muscle relaxation has been demonstrated experimentally. Secondary skeletal muscle relaxation due to ataraxia should be regarded as additive to this primary effect.

Atarax has been shown experimentally to have antispasmodic properties, apparently mediated through interference with the mechanism that responds to spasmogenic agents such as serotonin, acetylcholine and histamine. Antihistamine effects have been demonstrated experimentally and confirmed clinically.

An antiemetic effect, both by the apomorphine test and the veriloid test, has been demonstrated.

Indications: Atarax is indicated in the management of anxiety, tension and psychomotor agitation in conditions of emotional stress.

Atarax is also useful in alleviating the manifestations of anxiety and tension in situations in which the causative stress is temporary, as in the preparation for dental and other minor surgical procedures and in acute emotional problems. It has also been recommended for the management of anxiety associated with organic disturbances such as digestive disorders, dermatoses, senility, the menopausal syndrome and behaviour problems in children. In addition, it has been recommended as adjunctive therapy in alcoholism, and allergic conditions with strong emotional overlay, as in asthma, chronic urticaria and pruritus.

The efficacy of Atarax as adjunctive pre- and post-operative sedative medication has also been well established, especially as regards its ability to allay anxiety, control emesis and reduce the amount of narcotic required. Neither atropine nor the cardiac glycosides are affected by Atarax.

Dosage and administration Dosage varies with individual requirements and ranges from 25 mg t.i.d. to 100 mg q.i.d. The usual children's dose is as follows:

Under 6 years: 30–50 mg daily in divided doses.

Over 6 years: 50–100 mg daily in divided doses.

As with all potent medications, the dosage should be adjusted according to the patient's response to therapy.

Contra-indications, warnings, etc

Contra-indications: Atarax is contra-indicated in patients who have shown a previous hypersensitivity to it.

Warnings: Atarax may potentiate the action of central nervous system depressants. If central nervous system depressants and Atarax are used concurrently, then dosage should be reduced.

Side-effects: No serious side-effects have been reported and confirmed in the administration of Atarax to date. Therapeutic doses of Atarax seldom produce impairment of mental alertness. However, drowsiness may occur; if so, it is usually transitory and may disappear in a few days of continued therapy or upon reduction of the dose. Dryness of the mouth may be encountered at higher doses.

Extensive clinical use has substantiated the absence of toxic effects on the blood or liver when administered in the recommended doses for over four years of uninterrupted therapy. The absence of adverse effects has been further demonstrated in experimental studies in which excessively high doses were administered.

Involuntary motor activity, including rare instances of tremor and convulsions, has been reported, usually with doses considerably higher than those recommended. Continuous therapy with over 1 g per day has been employed in some patients without these effects having been encountered. Pharmacological and clinical studies indicate that Atarax in therapeutic dosage does not increase gastric secretion or acidity and in most cases provides mild antisecretory benefits.

Use in pregnancy: Atarax, when administered to the pregnant mouse, rat and rabbit, induced foetal abnormalities in the rat at doses substantially above the human therapeutic range. Clinical data in human beings are inadequate to establish safety in early pregnancy. Until such data are available, Atarax should be used in pregnancy only when in the judgement of the physician the expected benefits outweigh the potential hazards to the mother and the foetus.

Overdosage: Gastric lavage. Sedation with paraldehyde or sodium phenobarbitone intramuscularly if marked CNS irritation.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities *Tablets 10 mg:* Packs of 100.
Tablets 25 mg: Packs of 100.
Syrup: Bottle of 150 ml.

DELTACORTRIL* 'ENTERIC'

Presentation Deltacortril 'Enteric' tablets 2.5 mg uniformly brown in colour and coded 'Pfizer'.

Deltacortril 'Enteric' tablets 5 mg uniformly red in colour and coded 'Pfizer'.

Deltacortril is the synthetic crystalline steroid prednisolone.

Deltacortril 'Enteric' offers prednisolone in a specially balanced enteric coating which keeps the steroid from contact with the stomach and allows the tablet to disintegrate immediately on entering the jejunum.

Uses **Actions:** Naturally occurring glucocorticoids (hydrocortisone and cortisone) which possess salt-retaining properties, are used as replacement therapy in adrenocortical deficiency states. Their synthetic analogues are primarily used for their potent anti-inflammatory effects in disorders of many organ systems.

Deltacortril (prednisolone) is a synthetic steroid with powerful anti-inflammatory hormonal and metabolic effects similar to those of hydrocortisone. Deltacortril (prednisolone) has four times the glucocorticoid potency of hydrocortisone, with a lesser tendency to cause sodium retention.

Glucocorticoids cause profound and varied metabolic effects. In addition, they modify immune responses of the body to diverse stimuli.

Indications: **Endocrine disorders:** Primary or secondary adrenocortical insufficiency. (Hydrocortisone or cortisone is the drug of choice; synthetic analogues may be

used in conjunction with mineralocorticoids where applicable; in infancy mineralocorticoid supplementation is of particular importance.)

Congenital adrenal hyperplasia.

Non-suppurative thyroiditis.

Hypercalcaemia associated with cancer.

Rheumatic disorders: As adjunctive therapy for short-term administration (during an acute episode or exacerbation) in:

Psoriatic arthritis.

Rheumatoid arthritis (selected cases may require low-dose maintenance).

Acute gouty arthritis.

Ankylosing spondylitis.

Acute and subacute bursitis.

Juvenile rheumatoid arthritis.

Collagen diseases: Systemic lupus erythematosus.

Dermatomyositis.

Periarteritis nodosa.

Systemic sclerosis.

Acute rheumatic carditis.

Dermatological diseases: Pemphigus.

Bullous dermatitis herpetiformis.

Severe erythema multiforme (Stevens-Johnson syndrome).

Exfoliative dermatitis.

Mycosis fungoides.

Severe psoriasis.

Allergic states: Control of severe or incapacitating allergic conditions refractory to adequate trials of conventional treatment.

Seasonal or perennial allergic rhinitis.

Bronchial asthma.

Contact dermatitis.

Atopic dermatitis.

Serum sickness.

Angio-neurotic oedema.

Urticaria.

Ophthalmic diseases: Severe acute and chronic allergic and inflammatory processes involving the eye and its adnexa such as:

Allergic conjunctivitis.

Keratitis.

Allergic corneal marginal ulcers.

Herpes zoster ophthalmicus.

Iritis and iridocyclitis.

Chorioretinitis.

Anterior segment inflammation.

Diffuse posterior uveitis and choroiditis.

Optic neuritis.

Sympathetic ophthalmia.

Respiratory diseases: Symptomatic sarcoidosis.

Loeffler's syndrome not manageable by other means.

Fulminating or disseminated pulmonary tuberculosis when accompanied by appropriate antituberculous chemotherapy.

Berylliosis.

Pulmonary emphysema where bronchospasm or bronchial oedema plays a significant role.

Diffuse interstitial pulmonary fibrosis (Hamman-Rich syndrome).

Haematological disorders: Autoimmune haemolytic anaemia.

Idiopathic and secondary thrombocytopenia in adults.

Erythroblastopenia (RBC anaemia).

Congenital (erythroid) hypoplastic anaemia.

Gastro-intestinal diseases: To assist the patient during a critical period of disease in:

- Ulcerative colitis.
- Regional ileitis.

Neoplastic diseases: For palliative management of:

- Leukaemias and lymphomas in adults.
- Acute leukaemia of childhood.

Oedematous states: To induce a diuresis or remission of proteinuria in nephrotic syndrome, without uraemia, of the idiopathic type or that due to lupus erythematosus.

In conjunction with diuretic agents, to induce a diuresis in cirrhosis of the liver with refractory ascites.

Miscellaneous: Tuberculous meningitis with subarachnoid block or impending block when accompanied by appropriate antituberculous chemotherapy.

Dosage and administration The initial dosage of Deltacortril 'Enteric' tablets may vary from 5–60 mg daily depending on the specific disease entity being treated. In situations of less severity, lower doses will generally suffice while in selected patients higher initial doses may be required. The initial dosage should be maintained or adjusted until a satisfactory response is noted. If after a reasonable period of time there is a lack of satisfactory clinical response, Deltacortril 'Enteric' tablets should be discontinued and the patient transferred to other appropriate therapy. It should be emphasised that dosage requirements are variable and must be individualised on the basis of the disease under treatment and the response of the patient. After a favourable response is noted, the proper maintenance dosage should be determined by decreasing the initial drug dosage in small amounts at appropriate time intervals until the lowest dosage which will maintain an adequate clinical response is reached. Constant monitoring is needed in regard to drug dosage. Included in the situations which may make dosage adjustments necessary are changes in clinical status secondary to remissions or exacerbations in the disease process, the patient's individual drug responsiveness and the effect of patient exposure to stressful situations not directly related to the disease entity under treatment. In this latter situation, it may be necessary to increase the dosage of Deltacortril 'Enteric' tablets for a period of time consistent with the condition of the patient. If after long-term therapy the drug is to be stopped, it is recommended that it be withdrawn gradually rather than abruptly.

Contra-indications, warnings, etc

Contra-indications: Systemic fungal infections.

Warnings: Deltacortril should be used with great caution in the presence of a diminished cardiac reserve or congestive heart failure, diabetes mellitus, infectious diseases, chronic renal failure, uraemia and in elderly persons.

Patients on corticosteroid therapy subjected to unusual stress require increased dosage before, during and after the stressful situation.

Corticosteroids may mask some signs of infection and new infections may appear during their use. There may be decreased resistance and inability to localise infection when corticosteroids are used.

Average and large doses of hydrocortisone or cortisone can cause elevation of blood pressure, salt and water retention and increased excretion of potassium. These effects are less likely to occur with the synthetic derivatives except when used in large doses. Dietary salt

restriction and potassium supplementation may be necessary. All corticosteroids increase calcium excretion.

While on corticosteroid therapy, patients should not be vaccinated against smallpox. Other immunisation procedures should not be undertaken in patients who are on corticosteroids, especially on high dose, because of possible hazards of neurological complications and a lack of antibody response.

The use of Deltacortril in active tuberculosis should be restricted to those cases of fulminating or disseminated tuberculosis in which the corticosteroid is used for the management of the disease in conjunction with an appropriate antituberculous regimen.

Use in pregnancy: Since adequate human reproduction studies of corticosteroids are not available, the use of these drugs in pregnancy, nursing mothers or women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards to the mother and foetus. Infants born of mothers who have received substantial doses of corticosteroids during pregnancy should be carefully observed for signs of hypoadrenalism.

Precautions: Drug-induced secondary adrenocortical insufficiency may be minimized by gradual reduction of dosage. This type of relative insufficiency may persist for months after discontinuation of therapy, therefore, in any situation of stress occurring during that period, hormone therapy should be reinstituted. Since mineralocorticoid secretion may be impaired, salt and/or a mineralocorticoid should be administered concurrently.

There is an enhanced effect of corticosteroids in patients with hypothyroidism and in those with cirrhosis.

Corticosteroids should be used cautiously in patients with ocular herpes simplex because of possible corneal perforation.

The lowest possible dose of corticosteroid should be used to control the condition under treatment, and when reduction in dosage is possible, the reduction should be gradual.

Psychic derangements may appear when corticosteroids are used, ranging from euphoria, insomnia, mood swings, personality changes and severe depression, to frank psychotic manifestations. Also, existing emotional instability or psychotic tendencies may be aggravated by corticosteroids.

Aspirin should be used cautiously in conjunction with corticosteroids in hypoprothrombinaemia.

Steroids should be used with caution in non-specific ulcerative colitis, if there is a probability of impending perforation, abscess or other pyogenic infection and also in diverticulitis, fresh intestinal anastomoses, active or latent peptic ulcer, renal insufficiency, hypertension, osteoporosis and myasthenia gravis.

Growth and development of infants and children on prolonged corticosteroid therapy should be carefully observed.

Adverse reactions: The following reactions have been reported with the use of corticosteroids:

Fluid and electrolyte disturbances:

- Sodium retention.
- Fluid retention.
- Congestive heart failure in susceptible patients.
- Potassium loss.
- Hypokalaemic alkalosis.
- Hypertension.

Musculoskeletal: Muscle weakness.

- Steroid myopathy.
- Loss of muscle mass.
- Osteoporosis.
- Vertebral compression fractures.
- Aseptic necrosis of femoral and humeral heads.
- Pathological fracture of long bones.

Gastro-intestinal: Peptic ulcer with possible subsequent perforation and haemorrhage.

- Pancreatitis.
- Abdominal distension.
- Ulcerative oesophagitis.

Dermatological: Hirsutism.

- Impaired wound healing.
- Thin fragile skin.
- Petechiae and ecchymoses.
- Facial erythema.
- Increased sweating.
- May suppress reactions to skin tests.

Neurological: Convulsions.

Increased intracranial pressure with papilloedema (pseudo-tumour cerebri) usually after cessation/reduction of treatment.

- Vertigo.
- Headache.

Endocrine: Menstrual irregularities.

Development of Cushingoid state.
Suppression of growth in children.
Secondary adrenocortical and pituitary unresponsive-ness, particularly in times of stress, as in trauma, surgery or illness.

- Decreased carbohydrate tolerance.
- Manifestations of latent diabetes mellitus.
- Increased requirements for insulin or oral hypoglycaemic agents in diabetics.

Ophthalmic: Posterior subcapsular cataracts.

- Increased intraocular pressure.
- Glaucoma.
- Exophthalmos.

Metabolic: Negative nitrogen balance due to protein catabolism.

Overdose: Treat symptomatically with attention to serum electrolytes.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Deltacortril 'Enteric' tablets 2.5 mg and 5 mg, Packs of 100 and 500.

Further information Nil.

- 2.5 mg tablets 0057/5012
- 5 mg tablets 0057/0128

DIABINESE®

Presentation Diabinese brand of chlorpropamide is available as a white scored tablet in two different strengths:

- Diabinese 100 mg tablet ($\frac{3}{32}$ " diameter) coded DIA/100 on the one side and 'Pfizer' on the other.
- Diabinese 250 mg tablet ($\frac{3}{8}$ " diameter) coded DIA/250 on the one side and 'Pfizer' on the other.

Diabinese is classified as an arylsulphonylurea.

Uses Actions: Diabinese is absorbed rapidly from the gastro-intestinal tract. Within one hour after a single oral dose, it is readily detectable in the blood, and the level reaches a maximum within two to four hours. It is slowly excreted in the urine, for the most part as unchanged Diabinese. The biological half-life of Diabinese averages about 36 hours. Within 96 hours, 80–90% of a single oral dose is excreted in the urine. However, long-term administration of therapeutic doses does not result in undue accumulation in the blood, since absorption and excretion rates become stabilised in about five to seven days after the initiation of therapy.

Diabinese exerts a hypoglycaemic effect in normal humans within one hour, becoming maximal at three to six hours and persisting for at least 24 hours. The potency of Diabinese is approximately six times that of tolbutamide. Some experimental results suggest that its increased effectiveness may be the result of slower excretion and absence of significant deactivation.

The mode of action of Diabinese is believed to be that of stimulation of synthesis and release of endogenous insulin.

There is now evidence that improvement in pancreatic beta cell function, with consequent improvement in glucose tolerance, may occur with prolonged administration of Diabinese. Accordingly, in individuals with asymptomatic diabetes mellitus, principally manifested by an abnormal glucose tolerance, continuous use of Diabinese may result in 'normalisation' of their tolerance to glucose.

Diabinese does not interfere with the usual tests to detect albumin in the urine.

Indications: Diabinese is an oral hypoglycaemic agent. The precise mechanism of action is not completely understood but it is not an oral insulin.

Diabinese is a potent, active, oral hypoglycaemic agent indicated for the treatment of selected diabetic patients. It is generally used alone to control the mild to moderately severe maturity-onset, stable diabetic. While Diabinese is a sulphonamide derivative, it is devoid of antibacterial activity.

Diabinese is indicated in uncomplicated diabetes mellitus of the stable, mild or moderately severe, non-ketotic, maturity-onset type, which cannot be completely controlled by diet alone. It can often be used in patients of this type in place of insulin.

It may also prove effective in controlling certain patients who have shown an inadequate response or true primary or secondary failure to other sulphonylurea agents. In patients requiring high doses or frequent administration of another oral agent, control may be facilitated through its use.

Patient selection: The most likely patient for therapy is one in whom diabetes is of the maturity-onset type, stable, and not controllable by dietary regulation alone. A past history of diabetic coma does not necessarily preclude successful therapeutic control with Diabinese. A trial period may be indicated in certain patients who might be expected to respond to this type of medication, but who failed in initial trials with, or after having been on other oral sulphonylurea agents, or in patients whose diabetic control on such agents has not been satisfactory. Diabinese may prove effective and provide improved control of the diabetes. The final evaluation of response in patients who qualify as candidates for Diabinese is a therapeutic trial for a period of at least seven days. During the trial period, the absence of ketonuria together with a satisfactory reduction of glycosuria and hypergly-

caemia, or maintenance of previously satisfactory control, indicates that the patient is responsive and amenable to control with the drug. However, the development of ketonuria within 24 hours after withdrawal of insulin usually will be indicative of a poor response. The patient is considered non-responsive if he fails to achieve satisfactory lowering of blood sugar levels or fails to obtain objective or subjective clinical improvement and if he develops ketonuria or glycosuria. Insulin is indicated for the therapy of such patients.

Concurrent Diabinese – Biguanide therapy: The concurrent use of Diabinese with biguanide (phenformin, metformin) is indicated in the treatment of uncomplicated diabetes mellitus of the stable, non-ketotic, maturity-onset or adult type, which cannot be controlled by diet alone, by diet and insulin, or by diet and sulphonylurea agents. The appropriate biguanide data sheet should be consulted for complete details of patient selection, indications, warnings, and dose.

Diabinese in diabetes insipidus: Limited studies to date have shown that Diabinese is also useful in the treatment of idiopathic diabetes insipidus. In using Diabinese for this purpose, the physician must remain constantly aware of the possible occurrence of hypoglycaemic reactions in such individuals, particularly when unrelated illness, or other causes, reduce food intake. When Diabinese must be temporarily discontinued in such cases, therapy with antidiuretic hormone should be substituted.

In the treatment of diabetes insipidus, daily dosage has been in the range of 100–500 mg daily for older children and adults. Because of the risk of hypoglycaemia that can develop in these individuals, it is desirable to start therapy at the lower range, gradually adjusting the dose as indicated. Patients, and particularly the parents of children who are patients, should be warned of the possibility and treatment of hypoglycaemic reactions, especially during inter-current infections or other periods of impaired food intake. In such circumstances, Diabinese therapy should be promptly discontinued and the patient's physician contacted. When physicians are considering Diabinese for the treatment of diabetes insipidus, it is essential that they read this Data Sheet completely and particularly those paragraphs relating to Precautions and Adverse Reactions.

Dosage and administration The total daily dosage is generally taken as a single dose each morning with breakfast. A loading or priming dose is not necessary and should not be used. The occasional case of gastrointestinal intolerance may be relieved by dividing the daily dosage.

Initial therapy: The mild to moderately severe, middle-aged, stable diabetic patient should be started on 250 mg daily. Because the geriatric diabetic patient appears to be more sensitive to the hypoglycaemic effect of sulphonylurea drugs, older patients should be started on smaller amounts of Diabinese, in the range of 100–125 mg daily.

No transition period is necessary when transferring patients from other oral hypoglycaemic agents to Diabinese. The other agent may be discontinued abruptly and Diabinese started at once. In prescribing Diabinese, due consideration must be given to its greater potency.

The large majority of mild to moderately severe middle-aged, stable diabetic patients receiving insulin can be placed directly on the oral drug and their insulin abruptly discontinued. For patients requiring more than 40 units of insulin daily, therapy with Diabinese may be initiated

with a 50% reduction in insulin for the first few days, with subsequent further reductions dependent upon the response.

During the insulin withdrawal period, the patient should test his urine for sugar and ketone bodies at least three times daily and report the results frequently to his physician. If they are abnormal, the physician should be notified immediately. In some cases, it may be advisable to consider hospitalisation during the transition period.

Five to seven days after the initial therapy, the blood level of Diabinese reaches a plateau. Dosage may subsequently be adjusted upward or downward by increments of not more than 50–125 mg at intervals of three to five days to obtain optimal control. More frequent adjustments are usually undesirable.

Maintenance therapy: Most moderately severe, middle-aged stable diabetic patients are controlled by approximately 250 mg daily. Many investigators have found that some milder diabetics do well on daily doses of 100–125 mg or less. Many of the more severe diabetics may require 500 mg daily for adequate control. Patients who do not respond completely to 500 mg daily will usually not respond to higher doses. Maintenance doses above 500 mg should be avoided.

Diabinese/Phenformin dosage: The dosage of Diabinese should be maintained at or increased to 500 mg. If control is still inadequate, phenformin may be added in accordance with the dosage recommendation appearing in the phenformin data sheet. In no case should the daily dose of phenformin exceed 100 mg.

If adequate control is obtained without side-effects, reduction in dosage of both Diabinese and phenformin should be undertaken slowly (reducing the dosage of one drug at a time) in an attempt to maintain control with the least possible medication.

Diabinese/Metformin dosage: The dosage of Diabinese should be maintained at or increased to 500 mg. If control is still inadequate, metformin may be added at a dosage of 0.5 g b.i.d., increasing by 0.5 to 1.0 g every one to two weeks to a maximum of 3 g daily.

If adequate control is obtained without side-effects, reduction in dosage of both Diabinese and metformin should be undertaken slowly (reducing the dosage of one drug at a time) in an attempt to maintain control with the least possible medication.

Contra-indications, warnings, etc Use of Diabinese is not indicated in patients having:

Juvenile or growth-onset diabetes mellitus.

Severe or unstable 'brittle' diabetes.

Diabetes complicated by ketosis and acidosis, diabetic coma, major surgery, severe infection, or severe trauma.

Diabinese is contra-indicated in patients with serious impairment of hepatic, renal or thyroid function.

Use in pregnancy: Diabinese is contra-indicated during pregnancy. Safe conditions for the use of Diabinese in pregnancy have not been established and serious consideration should be given to the potential hazard of its use in women of childbearing age who may become pregnant.

Precautions: Since animal studies suggest that the action of barbiturates may be prolonged by therapy with Diabinese, barbiturates should be employed with caution. Similarly, studies showing an exaggerated hypoglycaemic effect of Diabinese in adrenalectomised animals suggest cautious use in patients with Addison's disease. In some patients, a disulfiram-like reaction may be produced by the ingestion of alcohol.

Caution should be exercised when antibacterial sulphonamides, phenylbutazone, salicylates, probenecid, dicoumarol, or MAO inhibitors are administered concomitantly with Diabinese as hypoglycaemia resultant from either potentiation or accumulation of sulphonylureas has been reported.

During the first six weeks of therapy, the physician should be in contact with the patient at least once a week. During this initial period, the patient must be observed for evidence of occasional drug reactions as described in the Adverse Reactions section. Because of the possibility of the following manifestations of hypersensitivity the patient should be instructed to report immediately to his physician if he does not feel as well as usual, or notes any pruritus, rash, jaundice, dark urine, light coloured stools, low-grade fever, sore throat or diarrhoea. As with all drugs, careful attention must be given to weigh the therapeutic advantages against the nature and incidence of side-effects.

During the period of transition to Diabinese, the patient's urine should be tested for sugar and acetone at least three times daily and the results reviewed by the physician at least once a week. Frequent laboratory determinations of liver function should also be seriously considered. Although transient minor alterations, particularly of cephalin flocculation, thymol turbidity, and serum alkaline phosphatase levels are not unusual and are probably of no clinical significance, a progressive rise in the alkaline phosphatase value should alert the physician to the possibility of incipient biliary stasis and jaundice and chlorpropamide therapy should be promptly discontinued. After the initial six weeks of therapy, subsequent patient-physician contacts may be at less frequent intervals, the exact frequency dependent on the judgement of the physician.

The drug should be used as an adjunct to, not a substitute for, dietary regulation, for this remains the primary consideration of diabetic management. It does not alter the need to educate the patient to such standard prophylactic and therapeutic measures as weight and exercise control, proper hygiene, and prompt care of intercurrent infection.

Alcohol and decreased diet may lead to hypoglycaemia, ketosis, coma, and death. Thiazides, on the other hand, have been shown to suppress insulin secretion and therefore will contribute to hyperglycaemia.

Warnings: Diabinese should not be used in juvenile diabetes or in diabetes complicated by acidosis, coma, severe infection, major surgical procedures or severe trauma. Here, insulin is indispensable.

Although Diabinese given alone has controlled some patients with mild maturity-onset diabetes of the stable type during the stress of mild infection or minor surgery, insulin therapy is generally essential during intercurrent complications (for example, ketoacidosis, severe trauma, major surgical procedures, severe infections, severe diarrhoea, nausea and vomiting, etc.). The severity of the diabetes, the nature of the complication, and availability of laboratory facilities determine whether therapy with Diabinese can be continued or should be withdrawn while insulin is being used.

In case of accidental ingestion by children, due note should be taken of the fact that three to five days are required for complete elimination of Diabinese from the body, and the patient should be kept under close observation for this period of time despite apparent recovery.

Since insulin still remains the standard therapy for patients during periods of stress or complication, the

patient on Diabinese must be instructed in the use of insulin. The patient must also be alerted to the early detection and prompt treatment of hypoglycaemia since this complication, although less frequent, may develop on sulphonylurea therapy as well as on insulin therapy.

During the initial period of therapy with Diabinese, hypoglycaemic reactions may occasionally occur, particularly during the transition from insulin to oral drug. Hypoglycaemia within 24 hours after withdrawal of the intermediate or long-acting types of insulin will usually prove to be the result of insulin carry-over and not primarily due to the effect of Diabinese.

Adverse reactions: The majority of side-effects have been dose-related, transient, and have responded to dose reduction or withdrawal of the medication. However, clinical experience thus far has shown that, as with other sulphonylureas, some side-effects associated with hypersensitivity may be severe and deaths have been reported in some instances.

Certain untoward reactions associated with idiosyncrasy or hypersensitivity have occurred, including jaundice, skin eruptions rarely progressing to erythema multiforme and exfoliative dermatitis, and probably depression of formed elements of the blood, show no direct relationship to the size of the dose. They occur characteristically during the first six weeks of therapy. With a few exceptions, these manifestations have been mild and readily reversible on the withdrawal of the drug.

The more severe manifestations may require other therapeutic measures, including corticosteroid therapy. Diabinese should be discontinued promptly when the development of sensitivity is suspected.

Jaundice has been reported and is usually promptly reversible on discontinuance of therapy. On the basis of considerable histopathological evidence, the jaundice is cholangiolitic and results primarily from intracanalicular biliary stasis rather than hepatocellular degeneration. The alkaline phosphatase which frequently shows serial and progressive elevation in these patients is of particular diagnostic value. The occurrence of progressive elevation should suggest the possibility of incipient jaundice and constitutes an indication for withdrawal of the drug.

In contrast, transient alterations of certain liver function tests seen occasionally following institution of sulphonylurea therapy, appear to be of no clinical significance.

Skin rash may be either the only manifestation of sensitivity, or occur in association with jaundice, frequently preceding it. Low grade fever and eosinophilia may also occur in association with, or preceding the development of, clinical jaundice. Rarely, severe diarrhoea, sometimes accompanied by bleeding into the lower bowel and due to non-specific proctocolitis, has been associated with other hypersensitivity manifestations, particularly jaundice, skin rash or both. The occurrence, singly or together, of any of these hypersensitivity manifestations, should constitute an indication for prompt termination of the drug and such other therapeutic measures as are dictated by the circumstances should be instituted.

Leucopenia, thrombocytopenia, and mild anaemia which occur occasionally, are generally benign and revert to normal, following cessation of the drug. Leucopenia of mild degree, and not associated with a shift in the differential count, may be transient and frequently reverts to normal even while the drug is continued.

Cases of aplastic anaemia and agranulocytosis, generally similar to blood dyscrasias associated with other

sulphonylureas have been reported. Lymphocytosis appears to be of no clinical significance.

Dose-related side-effects previously mentioned are generally transient and not of a serious nature and would include anorexia, nausea, vomiting and epigastric discomfort as evidence of gastro-intestinal intolerance, and various vague neurological symptoms, particularly weakness and paresthesiae. These manifestations are generally a direct function of dosage and were reported much more frequently during the early clinical history of the drug when some clinicians employed relatively high doses. These side-effects are reversible on reduction of the daily dosage, or if necessary, by withdrawal of the medication.

Administration of the total daily drug requirement in two doses rather than one is sometimes an effective measure for alleviating symptoms of gastro-intestinal intolerance.

Hypoglycaemia, although not a true side-effect but rather an exaggeration of the expected therapeutic action, may be the result of dosage in excess of the patient's immediate requirements, as is the case with any hypoglycaemic agent. Since the development of hypoglycaemia is a function of many factors including diet, this side-effect is at times seen in patients on the usual recommended dosage. It is readily controlled by administration of glucose. Its occurrence is an obvious indication for immediate re-evaluation and adjustment of the insulin or Diabinese dosage.

Because of the prolonged hypoglycaemic action of Diabinese patients who become hypoglycaemic during therapy with this drug require close supervision for a minimum period of three to five days, during which time frequent feedings or glucose administration are essential. The anorectic patient or the profoundly hypoglycaemic patient should be hospitalised.

Rare cases of phototoxic reactions have been reported.

Oedema associated with hyponatraemia has been infrequently reported with Diabinese therapy. This is thought to occur by potentiation of available ADH with subsequent water retention. The condition is usually readily reversible upon discontinuation of medication.

Overdosage: The treatment of hypoglycaemia is gastric lavage, intravenous glucose and haemodialysis.

Hypoglycaemia may be prolonged and treatment may have to be continued.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Diabinese 100 mg and 250 mg tablets are packed into blister strips of ten tablets each. These are available in packs of 100. Special packs of 500 tablets are also available for hospitals.

Further information Nil.

Product licence numbers

100 mg Tablets 0057/5015

250 mg Tablets 0057/5016

EQUIVERT*

Presentation Equivert brand of buclizine hydrochloride and nicotinic acid is available as a pale yellow tablet marked EVT on the one side and 'Pfizer' on the other side each containing 25 mg buclizine hydrochloride and 25 mg nicotinic acid.

Uses *Actions:* Nicotinic acid is a vasodilator agent. It

has been found effective in the treatment of vertigo due to Menière's syndrome, and to cerebral arteriosclerosis.

Buclizine hydrochloride is an antihistamine. It has been found effective in the treatment of migraine, Menière's syndrome, and vertigo.

Equivert is a combination of these two therapeutic agents. It is of value in the treatment of vertigo due to various causes, because the actions of these two therapeutically effective drugs are combined in one preparation.

Indications: Vertigo due to Menière's syndrome, cerebral arteriosclerosis, senility, labyrinthitis and streptomycin therapy. Recurrent headaches including migraine.

Dosage and administration One tablet to be taken three times daily before meals. Specific requirements for individual patients should be determined by the physician.

Contra-indications, warnings, etc *Precautions:* Since some drowsiness may occur with Equivert therapy, consideration should be given to occupational risks of the patient, such as driving or working at heights.

Equivert is indicated for use in adults only.

Use in pregnancy: As with other drugs, Equivert should be used in pregnancy only when, in the judgement of the physician, it is necessary for the welfare of the patient.

Side-effects: Short-lived flushing and tingling sensations may occur with Equivert therapy due to the vasodilator action of nicotinic acid. Patients should be made aware that such cutaneous reactions, together with increased gastro-intestinal motility and sebaceous gland activity, indicate that nicotinic acid therapy is taking effect and can be considered as desirable indications of therapeutic activity.

Drowsiness, headache or dryness of the mouth have been reported in a few patients.

Overdosage: Sedation with paraldehyde or sodium phenobarbitone intramuscular should be given if marked CNS irritation is present.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Pack of 100 tablets.

Further information Nil.

Product licence number 0057/5021.

FASIGYN* ▼

Presentation Fasigyn (tinidazole) is available as tablets or as an intravenous formulation. Tablets are white film coated tablets containing 500 mg of tinidazole. The intravenous formulation is presented in bottles of 400 ml and 800 ml containing 800 mg or 1600 mg of tinidazole (2 mg tinidazole per ml). Tinidazole is a cream to pale yellow crystalline solid with the chemical name: 1-[2-(ethylsulphonyl)ethyl]-2-methyl-5-nitroimidazole.

Uses Fasigyn is an agent for the treatment of infections due to susceptible obligate anaerobic bacteria. These infections are:

1. The treatment of infections in which anaerobic bacteria have been identified or are suspected as pathogens. The most important organisms are *Bacteroides fragilis*, other species of *Bacteroides* and *Fusobacterium*. Other organisms for which tinidazole is also

bactericidal belong to Species such as Peptococci, Peptostreptococci, Clostridia, Eubacteria and Veillonella.

Fasigyn has been successfully used in the treatment of the following infections from which one or more of the above organisms have been isolated: septicaemia, sinusitis, pneumonia, empyema and lung abscess, osteomyelitis, septic abortion, peritonitis and postoperative intra-abdominal sepsis, cellulitis and postoperative wound infection.

2. The prevention of postoperative infections caused by anaerobic bacteria, especially those after colonic, gastro-intestinal and gynaecological surgery.

3. The treatment of acute ulcerative gingivitis.

Intravenous Fasigyn is indicated in severe anaerobic infections or in those situations where oral treatment is impractical or impossible.

Dosage and administration

Oral Fasigyn: It is recommended that oral Fasigyn should be taken during or after a meal.

1. **Treatment of anaerobic infections:** An initial oral dose of 2 g followed by 1 g daily given as a single dose or as 500 mg twice daily.

Treatment for 5–6 days will generally be adequate but clinical judgement must determine the duration of therapy particularly when eradication of infection from certain sites may be difficult.

2. **Prevention of postoperative infections:** A single oral dose of 2 g with the last oral intake before operation.

3. **Acute ulcerative gingivitis:** A single oral dose of 2 g.

Intravenous Fasigyn

1. **Treatment of anaerobic infections:** An initial dose of 800 mg intravenously followed by 800 mg daily, until oral therapy is feasible. Oral therapy should be at a level of 1 g daily given as a single dose, or as 500 mg twice daily.

Treatment for 5–6 days will generally be adequate but clinical judgement must determine the duration of therapy particularly when eradication of infection from certain sites may be difficult.

Regular clinical and laboratory observation is advised if it is considered necessary to continue therapy for more than 7 days.

2. **Prevention of postoperative infections:** A total dose of 1600 mg tinidazole is recommended given either as a single pre-operative infusion or as two doses of 800 mg – the first dose 2–4 hours and not less than one hour prior to operation and a second dose of 800 mg approximately 12 hours later.

Administration of intravenous formulation: This should be given as an infusion of 800 mg (400 ml) in not less than 30 minutes or 1600 mg (800 ml) in not less than one hour.

Infusion with other intravenous solutions: intravenous tinidazole may be co-administered with the following frequently used intravenous solutions: 5% glucose, 20% glucose, isotonic saline, potassium chloride (20 mmol and 40 mmol).

No other medication should be added to Fasigyn Infusion, as chemical incompatibility may result. Fasigyn is, however, pharmacologically compatible with other antimicrobial agents.

Contra-indications, warnings, etc As with drugs of similar chemical structure, Fasigyn is contra-indicated in patients having, or with a history of, blood dyscrasia although no persistent haematological abnormalities

have been noted in clinical or animal studies. Fasigyn should not be administered to patients with a known hypersensitivity to the drug.

Fasigyn should be avoided in patients with organic neurological disorders.

Pregnancy: Fasigyn crosses the placental barrier and is present in the breast milk when administered to nursing mothers. Since the effects of compounds of this class on foetal developments or the new born are not definitely known, Fasigyn is contra-indicated during the first trimester of pregnancy and in nursing mothers during the neonatal period. While there is no evidence that Fasigyn is harmful during the later stages of pregnancy, its use during the last two trimesters of pregnancy requires that the potential benefits be weighed against possible hazards to mother and foetus.

Precautions: Although believed not to occur with Fasigyn, related compounds when taken together with alcoholic beverages have caused abdominal cramps, flushing and vomiting.

Drugs of similar chemical structure have also produced various neurological disturbances such as dizziness, vertigo, incoordination and ataxia. If, during therapy with Fasigyn, abnormal neurological signs develop, therapy should be discontinued.

Side effects: Mild side effects related to the gastrointestinal tract have been reported; these are rarely disturbing. Nausea and vomiting occur infrequently. As with related compounds, Fasigyn may produce transient leucopenia. Biochemical changes indicative of drug allergy have been reported. Mild thrombophlebitis has occasionally been observed at the infusion site.

Use in children: Fasigyn is not recommended for the treatment of children under the age of 12 years, as safe conditions for use of either the oral or intravenous formulation in this age group have not been established.

Overdosage: There is no specific treatment for gross overdosage of Fasigyn, but early gastric lavage is recommended following overdosage by mouth.

Pharmaceutical precautions

Tablets: store below 25°C in a dry place, away from light. **Intravenous formulation:** store below 25°C, away from light. 800 ml bottle – discard any unused solution.

Legal category POM.

Package quantities 20 x 500 mg tablets

Bottles of 400 ml or 800 ml intravenous infusion (2 mg/ml).

Further information Each 100 ml Fasigyn intravenous infusion includes 5.5 g dextrose monohydrate Ph.Eur.

Product licence numbers

500 mg tablet 0057/0150
Intravenous formulation 0057/0189

FELDENE* ▼

Presentation Feldene is available as a maroon and blue capsule, coded 'Pfizer' FEL 10 each containing 10 mg piroxicam.

Uses Feldene is a non-steroidal anti-inflammatory agent indicated for a variety of conditions requiring anti-inflammatory and/or analgesic activity, such as rheumatoid arthritis, osteoarthritis (arthrosis, degenerative

joint disease), ankylosing spondylitis, acute musculo-skeletal disorders and acute gout.

Dosage and administration *Rheumatoid arthritis, osteoarthritis, ankylosing spondylitis*: In these three indications, the recommended starting dose is 20 mg given as a single daily dose. The majority of patients will be maintained on 20 mg daily. A relatively small group of patients may be maintained on as little as 10 mg daily. Some patients may require up to 30 mg daily given in single or divided doses. Long term administration of doses 30 mg or higher carries an increased risk of gastrointestinal side-effects.

Acute Gout: Therapy should be initiated by a single dose of 40 mg followed on the next 4–6 days with 40 mg daily, given in single or divided doses. Feldene is not indicated for the long-term management of gout.

Acute musculoskeletal disorders: Therapy should be initiated with 40 mg daily for the first 2 days, given in single or divided doses. For the remainder of the 7 to 14 day treatment period, the dose should be reduced to 20 mg daily.

Contra-indications, warnings, etc

Contra-indications: Feldene should not be used in those patients with active peptic ulceration or a history of recurrent ulceration.

Feldene should not be used in those patients who have previously shown a hypersensitivity to the drug. The potential exists for cross sensitivity to aspirin and other non-steroidal anti-inflammatory drugs. Feldene should not be given to patients in whom aspirin and other non-steroidal anti-inflammatory drugs induce the symptoms of asthma, rhinitis or urticaria.

Warnings: *Use in pregnancy*: Although no teratogenic effects were seen in animal testing, the safety of Feldene used during pregnancy or during lactation has not yet been established. Feldene inhibits prostaglandin synthesis and release by an effect on prostaglandin biosynthetase. This effect, as with other non-steroidal anti-inflammatory agents, has been associated with an increased incidence of dystocia and delayed parturition in pregnant animals when drug administration was continued into late pregnancy.

Use in children: Dosage recommendations and indications for use in children have not been established.

Side-effects: Feldene is generally well tolerated. Gastro-intestinal symptoms are the most commonly encountered side-effects. Objective evaluations of gastric mucosal appearance and intestinal blood loss show that 20 mg/day Feldene administered either in single or divided daily doses is significantly less irritating to the gastrointestinal tract than aspirin.

Peptic ulceration and gastrointestinal bleeding have been reported.

Feldene should be withdrawn if peptic ulceration or gastrointestinal bleeding occurs.

As with other non-steroidal anti-inflammatory agents, blood urea nitrogen elevation has been observed in some patients. The rises in blood urea nitrogen are not progressive over the course of treatment with Feldene, a plateau being reached which returns to or towards the baseline levels if treatment is stopped. The rise in blood urea nitrogen is not associated with rises in serum creatinine.

Feldene, like other non-steroidal anti-inflammatory agents, decreases platelet aggregation and prolongs

bleeding time. This effect should be kept in mind when bleeding times are determined.

Long-term administration of doses of 30 mg or higher carries an increased risk of gastrointestinal side effects.

Skin rashes including dermal hypersensitivity have been reported. As with other non-steroidal anti-inflammatory drugs, Stevens-Johnson syndrome may develop in rare cases.

As with other non-steroidal anti-inflammatory agents, oedema, mainly ankle oedema, has been reported in a small percentage of patients.

As with other non-steroidal anti-inflammatory agents the possibility of precipitating congestive cardiac failure in elderly patients or those with compromised cardiac function should therefore be borne in mind.

Routine ophthalmoscopy and slit-lamp examination have revealed no evidence of ocular change.

Decreases in haemoglobin and haematocrit, unassociated with obvious gastrointestinal bleeding, have occurred. Changes in different liver function parameters have been observed. As with most other non-steroidal anti-inflammatory agents, some patients may develop increased serum transaminase levels during treatment with Feldene.

Overdosage: In the event of overdosage with Feldene, supportive and symptomatic therapy is indicated.

Pharmaceutical precautions Store in a cool, dry place.

Legal category POM.

Package quantities Capsules 10 mg – pack of 60.

Further information Feldene is highly protein bound, and therefore might be expected to displace other protein bound drugs. However, *in vitro* studies have shown this not to occur with dicoumarol. Nevertheless, the physician should closely monitor patients for change in dosage requirements when administering Feldene to patients on highly protein bound drugs.

Product licence number 0057/0145.

GLIBENESE*

Presentation Glibenese brand of glipizide is available as white oblong tablets marked GBS/5 on the scored side and 'Pfizer' on the other. Each tablet contains 5 mg glipizide.

Glipizide is 1-cyclohexyl-3-[[p(2-(5-methylpyrazine-2-carboxyamido) -ethyl)-phenyl]sulphonyl]-urea.

Uses **Actions**: Following oral administration, Glibenese is rapidly and almost completely absorbed. A peak plasma level is reached in one to two hours. Some 98% is protein bound. The plasma half-life is two and a half to four hours.

Glibenese is rapidly excreted, some 64–87% appearing in the urine within 24 hours; faecal excretion accounting for the remainder. Glibenese is excreted chiefly in the form of metabolites, the principal metabolites being 3-cis hydroxy and 4-trans hydroxy derivatives.

Following a single oral dose, a hypoglycaemic effect is seen in 30 minutes with a maximum response in two hours. Thereafter, the hypoglycaemic effect persists for over six hours on a diminishing scale.

Indications: Maturity-onset, non-ketotic, diabetes mellitus, not controlled by dietary measures alone.

Glibenese is not an oral insulin. As with other sulphonylureas, the blood glucose lowering capacity of

Glibenese is primarily attributable to a direct action on the beta cells of the pancreas.

Clinical studies have shown Glibenese to be a potent oral hypoglycaemic agent capable of producing satisfactory control in 80–90% of maturity-onset diabetic patients.

Dosage and administration Progress of the patient should be monitored with blood and urine glucose determinations. In order to achieve optimal control of the diabetic state, the dosage of Glibenese should be determined by, and adjusted to, the individual patient's requirement.

Newly diagnosed diabetics: Stabilisation may be carried out on an outpatient basis, starting normally with a daily dose of 5 mg of Glibenese given with breakfast or, if this meal is omitted, with the mid-day meal. Mild diabetic and geriatric patients should be started on 2.5 mg of Glibenese daily as these patients appear to be more sensitive to the sulphonylurea drugs.

Dosage must be adjusted according to the patient's response. If necessary, the daily dosage may be increased by 2.5 mg or 5 mg every three to five days until optimal control is achieved.

If the daily dosage requirement exceeds 10 mg the total daily dose should be subdivided and given in two parts with the two main meals of the day. Care should be taken to avoid hypoglycaemia.

Patients requiring daily doses in excess of 20 mg daily may require that their dosage be given in three parts with breakfast, the mid-day meal and the evening meal.

Maintenance therapy: Patients can usually be stabilised on a dosage varying from 2.5–30 mg daily.

Transfer from other oral agents: Patients poorly controlled on, or experiencing secondary failure with other antidiabetic agents may respond well to Glibenese. If, for these reasons, or previous adverse side effects a change is being made to Glibenese, it is recommended that a starting daily dose of 5 mg of Glibenese be instituted with adjustment upwards by increments of 2.5 or 5 mg daily so as to reach optimal control.

Patients receiving insulin: Maturity-onset diabetics with no ketoacidosis or history of metabolic decompensation and whose insulin requirements are less than 40 units per day may be considered for Glibenese therapy.

It is recommended that patients undergoing conversion from insulin to Glibenese be hospitalised under close physician observation.

Such patients should be carefully observed until optimal control is re-established, especially if the insulin is abruptly discontinued, or the dosage sharply decreased.

Concurrent Glibenese and biguanide therapy: As with other sulphonylureas, a proportion of patients who do not achieve optimal control with Glibenese alone, or who experience secondary failure, may be expected to have their control improved or restored by the addition of a biguanide.

For such patients, it is suggested that the dosage of Glibenese should be maintained and the biguanide chosen should be added using low doses initially and increasing the dosage of the biguanide progressively until adequate control is achieved or restored. Should gastro-intestinal side effects appear, an attempt should be made to reduce the dosage of the biguanide.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to Glibenese.

Diabetes complicated by ketoacidosis.

Juvenile, growth onset or brittle diabetes mellitus.

Severe renal or hepatic insufficiency.

Severe metabolic decompensation.

Use in pregnancy: Safe conditions for the use of Glibenese in pregnancy have not been established. Glibenese is not indicated for the management of diabetes mellitus during pregnancy.

Precautions: In patients subjected to stress, such as fever, trauma, infection or surgical procedures, it may be necessary temporarily to administer insulin instead of, or in addition to, Glibenese.

Patients with mild impairment of hepatic and/or renal function and debilitated or malnourished patients, require careful observation and adjustment of Glibenese dosage to avoid the occurrence of hypoglycaemia.

Care is also required when Glibenese is administered concurrently with certain other drugs which may potentiate its hypoglycaemic action. These include phenylbutazone, oxyphenbutazone, probenecid, salicylates, sulphonamides, chloramphenicol, coumarins, monoamine oxidase inhibitors and beta-adrenergic blocking agents.

Thiazide diuretics may aggravate the diabetic state and alter the Glibenese dosage required. Because of the potent hypoglycaemic activity of Glibenese, close dietary supervision is required during initial stabilisation to avoid the occurrence of hypoglycaemia. To date, hypoglycaemic episodes during Glibenese therapy have occurred only rarely.

Glibenese should be administered with or after meals. If hypoglycaemia occurs, conventional measures should be taken. Clinical experience to date indicates a prompt response may be expected.

Side-effects: Side-effects are uncommon with Glibenese. The side-effects reported consist mainly of gastro-intestinal disturbances (nausea, epigastric fullness, heartburn) – and headache. An antabuse effect has not been reported.

Overdosage: Hypoglycaemia may occur in those patients who do not eat regularly or who exercise without caloric supplementation, or in those who take Glibenese in the fasting state. Hypoglycaemia is treated in the usual manner, by supplying carbohydrate in various forms dependent on the patient's clinical status.

Pharmaceutical precautions Store in a cool dry place.

Legal category POM.

Package quantities Glibenese tablets 5 mg are packed into blister strips of ten tablets each. Available in cartons of 60 tablets.

Further information Nil.

Product licence number 0057/0113.

HYPOVASE®

Presentation Hypovase brand of prazosin hydrochloride is available in tablets as follows:

0.5 mg white tablets, unscored: marked 'Pfizer' on one side.

1 mg scored orange tablets: marked HYP/1 on one side.

2 mg scored white tablets: marked HYP/2 on one side and 'Pfizer' on the other.

5 mg scored white tablets: marked HYP/5 on one side and 'Pfizer' on the other.

Prazosin is 1-(4-amino-6, 7-dimethoxyquinazolin-2-yl)-4 (2-furoyl) piperazine.

Uses Actions: Hypovase causes a decrease in total peripheral resistance, but the exact mechanism of action is unknown. Animal studies suggest that the vasodilator effect of Hypovase is related to blockade of postsynaptic alpha-adrenoceptors. The results of dog forelimb experiments demonstrate that the peripheral vasodilator effect is confined mainly to the level of the resistance vessels (arterioles). Unlike conventional alpha-blockers the antihypertensive action of Hypovase is usually not accompanied by reflex tachycardia.

Haemodynamic studies have been carried out in hypertensive patients following acute single dose administration and during the course of long-term maintenance therapy. The results confirm that the usual therapeutic effect is a fall in blood pressure unaccompanied by a clinically significant change in cardiac output, heart rate, renal blood flow and glomerular filtration rate. In clinical studies where measurements were made, Hypovase has not increased plasma renin activity.

Clinically, the antihypertensive effect is believed to be a direct result of peripheral vasodilation. In man, blood pressure is lowered in both the supine and standing positions. This effect is more pronounced on the diastolic blood pressure. Tolerance does not appear to develop in long-term clinical use. Rebound elevation of blood pressure does not occur following abrupt cessation of Hypovase therapy.

Haemodynamic studies carried out in patients with congestive cardiac failure following acute oral dosing and during the course of longer term maintenance therapy both at rest and on exercise indicate that the therapeutic effect in these patients is due to a reduction in left ventricular filling pressure, reduction in cardiac impedance and an augmentation of cardiac output. These effects, as indicated in forearm plethysmographic studies in humans, are associated with a balanced vasodilator effect on both resistance vessels (arterioles) and capacitance vessels (veins). The use of Hypovase in congestive heart failure does not provoke a reflex tachycardia.

Following oral administration in normal volunteers and hypertensive patients plasma concentrations reach a peak in one to two hours with a plasma half-life of two to three hours. Pharmacokinetic data in a limited number of patients with congestive cardiac failure, most of whom showed evidence of hepatic congestion, indicates that peak plasma concentrations are reached in $2\frac{1}{2}$ hours and plasma half-life is approximately seven hours. The drug is highly bound to plasma protein. Animal studies indicate that Hypovase is extensively metabolized, primarily by demethylation and conjugation and excreted mainly via bile and faeces. Less extensive human studies suggest similar metabolism and excretion in man.

Hypovase has been administered without any adverse drug interaction in clinical experience to date with the following:

- cardiac glycosides – digitalis and digoxin;
- hypoglycaemic agents – insulin, chlorpropamide, phenformin, tolazamide, and tolbutamide;
- tranquilizers and sedatives – chlorthalidopoxide, diazepam, and phenobarbital;
- agents for the treatment of gout – allopurinol, colchicine, and probenecid;

- antiarrhythmic agents – procainamide and quinidine; and

- analgesic, antipyretic; and anti-inflammatory agents – propoxyphene, aspirin, indomethacin, and phenylbutazone.

Indications:

Hypertension: Hypovase is indicated in the treatment of hypertension of varied aetiology and all grades of severity. It can be used as the initial agent or it may be employed in a general treatment programme in conjunction with a diuretic and/or other antihypertensive drugs as needed for proper patient response.

Renal blood flow and glomerular filtration rate are not impaired by long-term oral administration and thus Hypovase can be used with safety in hypertensive patients with impaired renal function.

Congestive Cardiac Failure: Hypovase is indicated in the treatment of moderate to severe congestive cardiac failure. Hypovase may be added to the therapeutic regime in those patients who have not shown a satisfactory response or who have become refractory to conventional therapy with cardiac glycosides and diuretics.

Dosage and administration Hypertension: The dosage range is from 0.5–20 mg daily and treatment is best initiated at a low starting dose. It is recommended that the starting dose of 0.5 mg be given with food preferably with the evening meal, at least two or three hours before retiring.

The b.d. 'Starter Pack' is available for the convenience of prescribers to initiate treatment up to 2 mg b.d.

As is normal practice when potent antihypertensive agents are prescribed, patients should be advised how to recognise and how to avoid symptoms resulting from orthostatic hypotension and what measures to take should they develop. Patients should be cautioned to avoid situations where injury could result (e.g. driving or operating machinery) should dizziness or fainting occur during the initiation of Hypovase therapy.

Specific Recommendations: The following are given as guides to administration.

Patients receiving no antihypertensive therapy: It is recommended that therapy be initiated at 0.5 mg b.d. or t.i.d. for 3–7 days, with the starting dose administered in the evening. Unless poor acceptance suggests the patient is unusually sensitive, this dose should be increased to 1 mg b.d. or t.i.d. for the next 3–7 days.

Thereafter, if necessary, the daily dose should be increased gradually as determined by the patient's response to the blood pressure lowering effect. A significant number (of the order 60–70%) of patients are likely to be maintained on a dosage regimen of Hypovase alone of up to 15 mg daily in divided doses. Maximum recommended daily dosage: 20 mg in divided doses.

An increase in therapeutic effect may be achieved by adding a thiazide (e.g. polythiazide). When adding a thiazide, the dosage of Hypovase being administered should be reduced (e.g. halved) and subsequently adjusted as necessary.

Patients receiving thiazide diuretic therapy with inadequate control of blood pressure: The diuretic should be reduced to a low-dose level for the particular agent and Hypovase initiated at 0.5 mg b.d. or t.i.d. for 3–7 days with the starting dose administered in the evening. Unless poor acceptance suggests the patient is unusually sensitive, the dose should be increased to 1 mg b.d. or t.i.d. for the next 3–7 days.

ata sheet relating to these

In patients with congestive cardiac failure: Hypovase is
not recommended in the treatment of congestive cardiac
failure due to mechanical obstruction such as aortic
valve stenosis, mitral valve stenosis, pulmonary embolism
and restrictive pericardial disease. Adequate data is not
yet available to establish efficacy in patients with
congestive cardiac failure due to a recent myocardial
infarction.

Precautions: In patients with hypertension: A small
percentage of patients may react more rapidly and to a
greater extent than the majority. In some cases this has
led to sudden loss of consciousness generally lasting a
few minutes but which has been up to one hour. In
almost all such cases such a reaction occurs within 30 to
90 minutes of receiving the initial dose, but in a very few
instances may occur after a period of uneventful
treatment. Even when such a response occurs subse-
quent treatment may be satisfactory.

In patients with congestive cardiac failure: In patients
with acute or chronic left ventricular failure who have
undergone vigorous diuretic or vasodilator treatment,
the resultant decrease in left ventricular filling may be
associated with a significant fall in cardiac output and
systemic blood pressure when prazosin is administered.
In such patients, a low initial dose of prazosin and
gradual titration with close observation is recommended.
(See dosage and administration.)

In occasional patients the clinical efficacy of Hypovase
has been reported to diminish after several months of
treatment. In these patients there is usually evidence of
weight gain or peripheral oedema indicating fluid
retention. Since spontaneous deterioration may occur in
such severely ill patients a causal relationship to prazosin
therapy has not been established. Thus, as with all
patients with congestive cardiac failure, careful adjust-
ment of diuretic dosage according to the patient's clinical
condition is required to prevent excessive fluid retention
and consequent relief of symptoms. In those patients
without evidence of fluid retention, when clinical im-
provement has diminished, an increase in the dosage of
Hypovase will usually restore clinical efficacy.

Side-effects: In patients with hypertension: Side-effects
associated with the use of Hypovase have generally
been mild and usually not an indication for the discon-
tinuance of therapy. The most common side-effects
reported with the use of Hypovase consist of the
following: postural dizziness, drowsiness, headache, lack
of energy, weakness, palpitations, nausea, dry mouth,
blurred vision, urinary frequency, oedema, nasal conges-
tion, nervousness, depression, vertigo, constipation,
dyspnoea, vomiting, diarrhoea, syncope, rash, pruritus,
sweating, abdominal discomfort and/or pain, tachycar-
dia, paraesthesia, impotence, reddened sclera, epistaxis,
and tinnitus. The majority of patients who receive
Hypovase at the recommended dose will not experience
troublesome orthostatic effects.

Some of these reactions have occurred rarely and in
many instances the exact causal relationship has not
been established.

In patients with congestive cardiac failure: The following
have been observed in patients being managed for
moderate to severe congestive cardiac failure with
Hypovase when used in conjunction with cardiac
glycosides and diuretics. Drowsiness, dizziness, ortho-
static hypotension, blurred vision, oedema, dry mouth,
palpitations, nausea, headache, impotence, diarrhoea
and nasal congestion. In most instances these occur-
rences have been mild to moderate in severity and have

resolved with continued therapy or have been tolerated with no decrease in drug dose.

Overdosage: Should overdosage lead to hypotension, support of the cardiovascular system is of first importance. Restoration of blood pressure and normalisation of heart rate may be accomplished by keeping the patient in the supine position. If this measure is inadequate, shock should first be treated with volume expanders. If necessary vasopressors should then be used. Renal function should be monitored and supported as needed. Laboratory data indicate Hypovase is not dialysable because it is protein bound.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities *b.d. Starter Pack:* containing 8 × 0.5 mg Hypovase tablets and 32 × 1 mg Hypovase tablets (See 'Further Information').

Hypovase 0.5 mg: white tablets, unscored in packs of 100.

Hypovase 1 mg: scored orange tablets in packs of 100.

Hypovase 2 mg: scored white tablets in packs of 100.

Hypovase 5 mg: scored white tablets in packs of 100.

Further information The two week *b.d.* Starter Pack has the following instructions to the patient:

Step 1. (0.5 mg tablets) – 4 days, first dose in the evening.

Step 2. (1 mg tablets) – 4 days, first dose in the evening.

Step 3. (2 × 1 mg tablets) – 6 days, first dose in the evening.

Your doctor will wish you to follow further dosage instructions beyond step 3 and you should follow those instructions or see your doctor before the end of Step 3.

The tablets (0.5 and 1 mg) are carefully packed in sequence, in blister strips to ensure correct usage.

NEPHRIL®

Presentation Nephрил is available as white scored tablets ($\frac{3}{8}$ " diameter) coded NEP/1 on one side and 'Pfizer' on the other, each containing 1 mg polythiazide.

Uses *Actions:* The mechanism of action results in an interference with the renal tubular mechanism of electrolyte reabsorption. At maximal therapeutic dosage, all thiazides are approximately equal in their diuretic potency. The mechanism whereby thiazides function in the control of hypertension is unknown.

Indications: Nephрил brand of polythiazide is an orally effective, non-mercurial diuretic, saluretic and antihypertensive agent. Nephрил is indicated as adjunctive therapy in oedema associated with congestive heart failure, hepatic cirrhosis and corticosteroid and oestrogen therapy.

Nephрил has also been found useful in oedema due to various forms of renal dysfunction, such as nephrotic syndrome, acute glomerulonephritis and chronic renal failure.

Nephрил is indicated in the management of hypertension either as the sole therapeutic agent or to enhance the

effectiveness of other antihypertensive drugs in the more severe forms of hypertension.

Dosage and administration The usual dosage of Nephрил for diuretic therapy is 1 to 4 mg daily. For antihypertensive therapy the usual maintenance dose is between 1 and 4 mg daily although some patients may be optimally controlled on doses of 0.5 mg daily. However, few patients will require doses as high as 4 mg daily and at such a dose level serum electrolytes should be monitored frequently. Dosage should be individualised according to response and should be titrated to gain the maximum therapeutic effect with the minimum dose required to maintain that therapeutic response.

Contra-indications, warnings, etc

Contra-indications: Anuria. Hypersensitivity to polythiazide or other sulphonamide derived drugs.

Warnings: Thiazides should be used with caution in severe renal disease. In patients with renal disease, thiazides may precipitate azotaemia. Cumulative effects of the drug may develop in patients with impaired renal function. If progressive renal impairment becomes evident, as indicated by a rising nonprotein nitrogen or blood urea nitrogen, a careful reappraisal of therapy is necessary with consideration given to withholding or discontinuing diuretic therapy. Thiazides should be used with caution in patients with impaired hepatic function or progressive liver disease, since minor alterations of fluid and electrolyte balance may precipitate hepatic coma.

Thiazides may add to or potentiate the action of other antihypertensive drugs. Potentiation occurs with ganglionic or peripheral adrenergic blocking drugs.

Sensitivity reactions may occur in patients with a history of allergy or bronchial asthma. The possibility of exacerbation or activation of systemic lupus erythematosus has been reported.

Use in pregnancy: The routine use of diuretics in healthy pregnant women is inappropriate and may expose mother and foetus to unnecessary hazard. Diuretics do not prevent development of toxæmia of pregnancy and there is no satisfactory evidence that they are useful in the treatment of established toxæmia.

Oedema during pregnancy may arise from pathological causes or from physiological and mechanical consequences of pregnancy. Physiological hypervolaemia during pregnancy may be associated with generalised oedema including dependent oedema. This oedema is properly treated by recumbency and support hose. Thiazides may be indicated in pregnancy when oedema is due to pathological causes other than toxæmia. Rarely short courses of thiazides are indicated where physiological oedema is unrelieved by rest and where the oedema causes extreme discomfort.

Thiazides cross the placental barrier and appear in cord blood. The use of thiazides in pregnant women requires that the anticipated benefit be weighed against possible hazards to the foetus. These hazards include foetal or neonatal jaundice, thrombocytopenia and possibly other adverse reactions which have occurred in the adult.

Nursing mothers: Thiazides appear in breast milk. If use of Nephрил is deemed essential, nursing should be discontinued.

Precautions: All patients receiving thiazide therapy should have periodic determinations of serum electrolytes to detect possible electrolyte imbalance. Such patients should also be observed for clinical signs of fluid or electrolyte imbalance; namely hyponatraemia,

hypochlorhaemic alkalosis and hypokalaemia. Serum and urine electrolyte determinations are particularly important when the patient is vomiting or receiving parenteral fluids. Warning signs of possible electrolyte imbalance, irrespective of cause, are: dryness of mouth, thirst, weakness, lethargy, drowsiness, restlessness, muscle pains or cramps, muscular fatigue, hypotension, oliguria, tachycardia and gastro-intestinal disturbances such as nausea and vomiting.

Hypokalaemia may develop with thiazides as with any other potent diuretic, especially with brisk diuresis, when severe cirrhosis is present, or during concomitant use of corticosteroids or ACTH.

Interference with adequate oral electrolyte intake will also contribute to hypokalaemia. Hypokalaemia may exaggerate metabolic effects of digitalis therapy especially with reference to myocardial activity.

Any chloride deficit is generally mild and usually does not require specific treatment except under extraordinary circumstances (as in liver disease or renal disease). Dilutional hyponatraemia may occur in oedematous patients in hot weather; appropriate therapy is water restriction, rather than administration of salt except in rare instances, when the hyponatraemia is life threatening. In actual salt depletion, appropriate replacement is the therapy of choice. Hyperuricaemia may occur or frank gout may be precipitated in certain patients receiving thiazide therapy.

Insulin requirements in diabetic patients may be increased, decreased or unchanged. Latent diabetes mellitus may become manifest during thiazide administration.

Thiazide drugs may increase the responsiveness to tubocurarine.

The antihypertensive effects of thiazides may be enhanced in the post-sympathectomy patient. Thiazides may decrease arterial responsiveness to noradrenaline. This diminution is not sufficient to preclude effectiveness of the pressor agent for therapeutic use.

Thiazides may decrease serum protein-bound iodine levels without signs of thyroid disturbance.

Use in children: Nephril is not recommended for use in children.

Adverse Reactions:

Gastro-intestinal – anorexia, gastric irritation, nausea, vomiting, cramping, diarrhoea, constipation, jaundice (intrahepatic cholestatic jaundice), pancreatitis.

Central nervous system – dizziness, vertigo, paraesthesia, headache, xanthopsia.

Haematological – leucopenia, agranulocytosis, thrombocytopenia, aplastic anaemia.

Dermatological – purpura, photosensitivity, rash, urticaria, necrotising angitis.

Cardiovascular – orthostatic hypotension may occur and be aggravated by alcohol, barbiturates or narcotics.

Other – hypoglycaemia, glycosuria, hyperuricaemia, muscle spasm, weakness, restlessness.

Whenever adverse reactions are moderate or severe, thiazide dosage should be reduced or therapy withdrawn.

Overdosage: Gastric lavage and supportive therapy. Treatment of acute renal failure if present. Potassium supplements.

Pharmaceutical precautions Store in a cool place.

RONDOMYCIN*

Presentation Rondomycin brand of methacycline hydrochloride is available as:

150 mg capsules coded 'Pfizer' on the red head of the capsule and coded RON 150 on the white body of the capsule.

Rondomycin is a potent broad-spectrum antibiotic, synthetically derived from oxytetracycline.

Uses **Actions:** Rondomycin is well absorbed following oral administration in man. Therapeutic blood levels are rapidly achieved after oral administration of a single 150 mg dose, with a maximum level attained between two and three hours and maintained for over 12 hours. Appreciable amounts of the antibiotic remain in the blood for 24 hours or more after a single administration.

In a double-blind study, Rondomycin produced stable therapeutic blood levels when given continuously for three days at a total daily dose of 600 mg administered in either two or four equally divided doses. Twenty-four hours after completion of the three day period of administration of Rondomycin, blood levels were still within therapeutic range. Rondomycin is excreted in the urine and bile and is partially eliminated unchanged in the faeces.

Rondomycin has a wide spectrum of microbiological activity. *In vitro* tests indicate its activity against both Gram-positive and Gram-negative organisms. *In vivo*, independent animal protection studies have shown Rondomycin to be active against experimental infections produced by *Staphylococcus aureus*, *Streptococcus pyogenes*, *Diplococcus pneumoniae*. In experimental infections with *Salmonella typhosa*, *Escherichia coli* and *Aerobacter aerogenes*, Rondomycin again has shown its effectiveness in protecting the animals.

Acute toxicity studies in mice and rats have shown a high therapeutic index and a wide margin of safety for Rondomycin. Chronic toxicity studies in rats and dogs for periods of three to six months have shown no significant alteration in tissue function.

Indications: Rondomycin is a potent, broadly active, antibiotic effective in the treatment of infections caused by sensitive organisms. Specific conditions which may be expected to respond successfully to Rondomycin therapy include the following:

Respiratory infections: Acute bronchitis and acute exacerbations of chronic bronchitis, bronchiectasis, bronchopneumonia, pneumonia, lung abscess and upper respiratory infections such as pharyngitis, tonsillitis, sinusitis and otitis. Rondomycin may be used as an antibacterial cover in virus infections of the respiratory tract, including influenza and primary atypical pneumonia.

Surgical infections: Abscess, cellulitis, etc. May be used as an antibacterial cover before and after surgery in susceptible infections.

Skin and soft tissue infections: Folliculitis, erysipelas, impetigo, furunculosis, pyoderma, carbuncle, paronychia, acne, etc.

Gastro-intestinal infections: Bacillary dysentery, salmonellosis, typhoid fever, etc. Biliary tract infections.

Genito-urinary infections: Cystitis, pyelitis, pyelonephritis, gonococcal urethritis, etc.

Generalised infections: Septicaemia, bacteraemia. May be used as an antibacterial cover during bacteraemic states in susceptible individuals.

Obstetric and gynaecological infections:

Oral and dental infections:

Dosage and administration Rondomycin is available as 150 mg capsules. Rondomycin has the property of maintaining therapeutic blood levels for at least 24 hours following interruption of several days continuous administration.

Adults: For infections of average severity, the recommended total daily dosage is 600 mg of Rondomycin administered in either two or four equally divided doses. In severe infections, this dosage may be doubled.

Contra-indications, warnings, etc

Contra-indications: Rondomycin is contra-indicated in individuals who have hypersensitivity to tetracyclines.

Rondomycin is contra-indicated in patients with renal failure.

Warnings: As with other antibiotics, side effects have been reported such as nausea, vomiting, increase in frequency of defaecation, diarrhoea, proctitis and stomatitis. Serious gastro-intestinal side-effects have rarely been noted. Reactions of an allergic nature may result, but have not yet been reported for Rondomycin.

As with all other broad spectrum antibiotics, the administration of Rondomycin may result in the overgrowth of nonsusceptible organisms. Constant observation of the patient is essential. Should superimposed infection occur during therapy, the antibiotic should be discontinued and suitable measures should be taken as indicated by susceptibility testing.

Tetracyclines may form a stable calcium complex in any bone forming tissue with no serious harmful effects reported thus far in humans. However, the use of tetracyclines during tooth development (last half of pregnancy, neonatal period and early childhood) may cause discoloration of the teeth (yellow-grey-brownish). This effect occurs mostly during long-term use of the drug but it has also been observed with the usual short treatment courses.

Overdosage: Acute overdosage with antibiotics is rare.

Toxic effects are usually due to hypersensitivity reactions and should be treated as such.

Pharmaceutical precautions Store in a cool place. Protect from light.

Legal category POM.

Package quantities Capsules 150 mg: Packs of 16, 100 and 500.

SAFAPRYN®

Presentation Safapryn brand of enteric-coated aspirin with paracetamol is available as:

Pink sugar-coated tablets each containing 300 mg aspirin as an enteric coated core, surrounded by an outer layer of 250 mg paracetamol.

Uses Actions: Gastric blood loss following the ingestion of aspirin occurs in over half the patients taking it in the standard form. The average daily loss in such patients has been estimated as 5 ml. Evidence suggests that the effect is a direct one on the gastric mucosa, and that enteric coating of the aspirin, ensuring release in the small intestine, reduces the incidence of blood loss. A trial (Brit. J. Clin. Pract., 1971, **25**, 169) using radioactive chromium labelled red blood cells has shown that the average daily blood loss following the ingestion of Safapryn is less than 1 ml.

Release of the aspirin in the small intestine, rather than in the stomach, results in some delay in the onset of analgesic effect and it is for this reason that the outer coat of the tablet contains paracetamol, which is absorbed rapidly, and which provides initial analgesic effect.

Safapryn is adequately absorbed and gives plasma salicylate levels comparable to those achieved with standard aspirin tablets.

Indications: Safapryn is an analgesic preparation designed to minimise the gastric irritation and blood loss associated with aspirin.

Safapryn is indicated in all conditions where a mild analgesic/anti-inflammatory would be prescribed such as headache, musculoskeletal pain, dysmenorrhoea, also for the long-term treatment of chronic painful conditions such as osteoarthritis and rheumatoid arthritis.

Dosage and administration *Chronic painful conditions:* 1 to 3 tablets (300 to 900 mg aspirin + 250 to 750 mg paracetamol) three or four times a day. Do not exceed 10 tablets in 24 hours.

Each tablet should be swallowed whole, not crushed or broken in any way.

Safapryn is indicated for use in adults only.

Contra-indications, warnings, etc

Contra-indications: Active peptic ulceration, haemophilia, hypersensitivity to either aspirin or paracetamol, hypoprothrombinaemia.

Warnings: An overdose of Safapryn can cause hepatic necrosis.

Precautions: Safapryn may enhance the effect of anti-coagulants. It may inhibit the action of uricosurics. Safapryn may precipitate bronchospasm. It may induce attacks of asthma in susceptible subjects.

Side-effects: Aspirin may cause tinnitus, rashes and anaphylactic phenomena. Skin eruptions and blood dyscrasias have been reported on rare occasions following prolonged administration of paracetamol.

Use in Pregnancy: Aspirin may prolong labour and contribute to maternal and neonatal bleeding and is best avoided at term.

Overdosage: Overdosage with Safapryn is rare but has been reported. High plasma paracetamol levels have occurred early whilst salicylate levels continued to rise for up to 70 hours after ingestion.

Early treatment of paracetamol overdosage with N-acetylcysteine or methionine is important to prevent liver damage. Treatment for salicylate overdosage such as forced diuresis and gastric lavage, can be determined by clinical features, plasma salicylate levels and biochemical parameters.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Pack of 250.

Further information Nil.

Product licence number 0057/5029.

SAFAPRYN* - CO

Presentation Safapryn-Co brand of enteric-coated aspirin with paracetamol and codeine phosphate is available as lime-green sugar-coated tablets each containing 300 mg aspirin as an enteric-coated core, 250 mg paracetamol and 8 mg codeine phosphate.

Uses Actions: Gastric blood loss following the ingestion of aspirin occurs in over half the patients taking it in the standard form. The average daily blood loss in such patients has been estimated as 5 ml. Evidence suggests that the effect is a direct one on the gastric mucosa and that enteric coating of the aspirin, ensuring release in the small intestine, reduces the incidence of blood loss.

Release of the aspirin in the small intestine, rather than in the stomach, results in some delay in the onset of analgesic effect and it is for this reason that the outer coat of the tablet contains paracetamol and codeine, which are absorbed rapidly and which provide initial analgesic effect.

Safapryn-Co is adequately absorbed and gives plasma salicylate levels comparable to those achieved with standard aspirin tablets.

Indications: Safapryn-Co is an analgesic preparation designed to minimise the gastric irritation and blood loss associated with aspirin.

Safapryn-Co is indicated in all acutely painful conditions where an analgesic would be prescribed: lumbago, fibrositis, sciatica, low back pain, prolapsed intervertebral disc, dysmenorrhoea, toothache and headache.

Dosage and administration 1 to 3 tablets (300 to 900 mg aspirin + 250 to 750 mg paracetamol + 8 to 24 mg codeine) three or four times a day. Do not exceed 10 tablets in 24 hours.

Each tablet should be swallowed whole, not crushed or broken in any way.

Safapryn-Co is indicated for use in adults only.

Contra-indications, warnings, etc

Contra-indications: Active peptic ulceration, haemophilia, hypersensitivity to either aspirin, paracetamol or codeine, hypoprothrombinaemia.

Warnings: An overdose of Safapryn-Co can cause hepatic necrosis.

Precautions: Safapryn-Co may enhance the effect of anticoagulants. It may inhibit the action of uricosurics. Safapryn-Co may precipitate bronchospasm. It may induce attacks of asthma in susceptible subjects. Codeine is a narcotic analgesic.

Side-effects: Aspirin may cause tinnitus, rashes and anaphylactic phenomena. Skin eruptions and blood dyscrasias have been reported on rare occasions following prolonged administration of paracetamol. Codeine may cause constipation.

Use in pregnancy: Aspirin may prolong labour and contribute to maternal and neonatal bleeding and is best avoided at term.

Overdose: To the present no reports of effects of overdose of Safapryn-Co have been received but it is anticipated that high levels of paracetamol will occur

early and salicylate levels may continue to rise for up to 70 hours after ingestion.

Early treatment of paracetamol overdose with N-acetylcysteine or methionine is important to prevent liver damage. Treatment for salicylate overdose such as forced diuresis and gastric lavage, can be determined by clinical features, plasma salicylate levels and biochemical parameters.

Reports of overdose with other codeine containing products suggest that this component is not usually the prime hazard.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Pack of 100.

Further information Nil.

Product licence number 0057/0064.

SINEQUAN*

Presentation Sinequan brand of doxepin is available in capsules of four strengths. All capsules bear the name 'Pfizer'.

The four sizes of capsules are distinguished by their colour and coding as follows:

Sinequan 10 mg capsule coded 'SQN 10' (opaque orange).

Sinequan 25 mg capsule coded 'SQN 25' (opaque blue cap/opaque orange body).

Sinequan 50 mg capsule coded 'SQN 50' (opaque blue).

Sinequan 75 mg capsule coded 'SQN 75' (opaque blue cap/opaque rich yellow body).

Sinequan contains a dibenzoxepin derivative which consists of a mixture of the *cis* and *trans* isomers in a constant ratio (82–85% *trans*: 15–18% *cis*). Chemically, it is 11-dimethyl-amino-propylidene-6H-dibenz(b,e)-oxepin hydrochloride.

Uses Actions: The mechanism of action of Sinequan is not definitely known. It is not a central nervous system stimulant nor a monoamine oxidase inhibitor. The current hypothesis is that the clinical effects are due, at least in part, to influences on the adrenergic activity at the synapses so that deactivation of norepinephrine by reuptake into the nerve terminals is prevented. Animal studies suggest that Sinequan does not appreciably antagonise the antihypertensive action of guanethidine. In animal studies anticholinergic, antiserotonin and antihistamine effects on smooth muscle have been demonstrated. At higher than usual clinical doses, norepinephrine response was potentiated in animals. This effect was not demonstrated in humans.

At clinical dosages up to 150 mg per day, Sinequan can be given to man concomitantly with guanethidine and related compounds without blocking the antihypertensive effect. At dosages above 150 mg per day blocking of the antihypertensive effect of these compounds has been reported.

There have been no reports of physical dependency or withdrawal symptoms associated with Sinequan therapy. This is consistent with the virtual absence of euphoria as a side-effect and at this dose there was no evidence of toxicity in rats and dogs over a 12 month period.

Indications: Sinequan is a safe and effective psychotherapeutic agent for the treatment of patients with a

wide range of psychoneurotic disorders where anxiety and/or depression are prominent symptoms.

Thus, where these prime symptoms are present, the compound has been shown to be of value in patients with anxiety neuroses, with or without somatic symptoms, reactive depression, mixed anxiety depression and patients with alcoholism with anxiety and/or depression.

In addition, Sinequan is similarly effective in the treatment of patients suffering from psychotic depression, including endogenous depression, involutional melancholia, senile depression, postpartum depression and manic-depressive reaction-depressed phase.

Target symptoms that respond to treatment include: anxiety, depression, tension, apprehension, agitation, functional somatic complaints, insomnia, loss of interest, guilt, psychomotor retardation and hypochondriasis.

Sinequan may be used with benefit where symptoms are of short or long duration prior to treatment and in patients with a wide range of intensity of illness.

As with other psychotherapeutic agents, the degree of response varies with each patient. In patients exhibiting a beneficial response, this may be seen within a few days of commencing therapy, while others may not respond for two weeks or longer.

Due to its excellent toleration, Sinequan is particularly useful in ambulatory patients seen in general practice as well as in the treatment of hospitalised patients.

Clinical studies have also demonstrated Sinequan to be effective in alleviating the temporary anxiety and tension associated with difficult diagnostic procedures such as endoscopies (gastroscopy, oesophagoscopy, bronchoscopy, cystoscopy, laparoscopy, etc.) performed under local anaesthesia.

Dosage and administration The optimum oral dose depends on the severity of the condition and the individual patient's response. The dose varies from 30–300 mg daily, and is usually administered in three divided doses daily.

As an alternative regimen, the total daily dosage, up to 100 mg may be given as a single dose without loss of effectiveness. This dose may be given at bedtime.

For patients where the presenting symptoms are mild in nature, it is advisable to initiate treatment at a dose of 30 mg daily. A good clinical response is obtained in many of these patients at a daily dose of 30–50 mg. The dosage may be adjusted according to the individual response.

For the majority of patients with moderate or severe psychoneurotic symptoms, it is recommended that treatment commences with an initial dose of 75 mg daily. Many of these patients will respond satisfactorily at this dose level. For patients who do not, the dosage may be adjusted according to individual response. In more severely ill patients, particularly where depression is the predominant presenting symptom, it may be necessary to administer a dose of up to 300 mg a day to obtain a clinical response.

In patients where insomnia is a troublesome symptom, it is recommended that the total daily dose be divided so that a higher proportion is given for the evening dose; similarly, if drowsiness is experienced as a side effect of treatment, Sinequan may be administered by this regimen, or the dosage may be reduced.

It is often possible, having once obtained a satisfactory therapeutic response, to reduce the dose for maintenance therapy.

The anti-anxiety effect is apparent before the anti-

depressant effect. Optimal antidepressant effect may not be evident for two to three weeks.

The temporary anxiety and tension associated with difficult diagnostic procedures such as endoscopy can be alleviated by the administration of either 20 mg the night before plus 10 mg in the morning, or a single dose of 25 mg two hours before the procedure, enabling the patient to become more relaxed and co-operative.

Contra-indications, warnings, etc

Contra-indications: Sinequan is contra-indicated in individuals who have shown hypersensitivity to the drug.

Sinequan is contra-indicated in patients with glaucoma or a tendency to urinary retention. These disorders should be excluded, particularly in older patients.

Warnings: The once-a-day dosage regimen of Sinequan in patients with intercurrent illness or patients taking other medications should be carefully adjusted. This is especially important in patients receiving other medications with anticholinergic effects.

The use of Sinequan on a once-a-day dosage regimen in geriatric patients should be adjusted carefully on the basis of the patient's condition.

Combined use with antidepressant, alcohol or anti-anxiety agents should be undertaken with due recognition of the possibility of potentiation. It is known, for example, that monoamine oxidase inhibitors may potentiate other drug effects, therefore patients who have been receiving MAO inhibitors, should have that therapy discontinued two weeks prior to receiving Sinequan.

Since drowsiness may occur with the use of Sinequan, patients should be warned of the possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Since suicide is an inherent risk in any depressed patient until significant improvement has occurred, patients should be closely supervised during early therapy.

Use in pregnancy: Although animal reproduction studies have not shown any teratogenic effect, Sinequan, as with all drugs, should be used in pregnancy only when, in the judgement of the physician, it is necessary for the welfare of the patient.

Use in children: The use of Sinequan in children under 12 years of age is not recommended, because safe conditions for its use have not been established.

Adverse effects: Note: Some of the adverse reactions noted below have not been specifically reported with Sinequan. However, due to the close pharmacological similarities amongst the tricyclics, the reactions should be considered when prescribing Sinequan.

Anticholinergic effects: Dry mouth, blurred vision, constipation and urinary retention have been reported. If they do not subside with continued therapy, or if they become severe, it may be necessary to reduce the dosage.

Central nervous system effects: Drowsiness is the most commonly noticed side-effect. This tends to disappear as therapy is continued. Other infrequently reported CNS side effects are confusion, disorientation, hallucinations, paraesthesiae, ataxia and extrapyramidal symptoms.

Cardiovascular: Cardiovascular effects including hypotension and tachycardia have been reported occasionally.

Allergic: Skin rash, facial oedema, photosensitisation and pruritis have occasionally occurred.

Haematological: Eosinophilia has been reported in a few patients. There have been occasional reports of bone marrow depression manifesting as agranulocytosis, leucopenia, thrombocytopenia and purpura.

Gastro-intestinal: Nausea, vomiting, indigestion, taste disturbances, diarrhoea and anorexia have been reported. (See Anticholinergic effects).

Endocrine: Raised or lowered libido, testicular swelling, gynecomastia in males, enlargement of breasts and galactorrhoea in the female, raising or lowering of blood sugar levels have been reported following the administration of tetracyclines.

Other: Dizziness, tinnitus, weight gain, sweating, chills, fatigue, weakness, flushing, jaundice and alopecia have been occasionally observed as adverse effects.

Overdosage: Supportive therapy, physostigmine for arrhythmias, metaraminol for hypotension, phenobarbitone intramuscular or thiopentone sodium for hyperreflexia and/or convulsions.

Pharmaceutical precautions Store in a cool place.

TERRAMYCIN®

Presentation Terramycin brand of oxytetracycline is available as follows:

Oral dosage forms.

Tablets 250 mg: Each sugar-coated yellow tablet contains 250 mg oxytetracycline as the dihydrate and coded 'Pfizer'.

Capsules 250 mg: Hard gelatin capsules, opaque yellow cap and body printed TER250 and 'Pfizer', each containing 250 mg oxytetracycline as the hydrochloride.

Topical dosage form.

Terramycin Ophthalmic Ointment with Polymyxin B Sulphate: A sterile preparation of oxytetracycline hydrochloride and polymyxin B sulphate in a special petrolatum base. Each gram of ointment contains 5 mg oxytetracycline as the hydrochloride and 10,000 units of polymyxin B as the sulphate.

Uses **Actions:** Terramycin is a product of the metabolism of *Streptomyces rimosus* and is one of the family of tetracycline antibiotics.

Terramycin is primarily bacteriostatic and is thought to exert its antimicrobial effect by the inhibition of protein synthesis. Terramycin is active against a wide range of Gram-negative and Gram-positive organisms.

The drugs in the tetracycline class have closely similar antimicrobial spectra and cross-resistance among them is common.

Tetracyclines are readily absorbed and are bound to

plasma proteins in varying degrees. They are concentrated by the liver in the bile and excreted in the urine and faeces in high concentrations and in a biologically active form.

Terramycin diffuses readily through the placenta into the foetal circulation, into the pleural fluid and, under some circumstances, into the cerebrospinal fluid.

Indications: Terramycin is a broad-spectrum antibiotic.

Terramycin is indicated in infections caused by the following micro-organisms:

Rickettsiae (Rocky Mountain spotted fever, typhus fever and the typhus group, Q fever, rickettsialpox and tick fevers).

Mycoplasma pneumoniae (PPLO, Eaton Agent).

Agents of psittacosis and ornithosis.

Agents of lymphogranuloma venereum and granuloma inguinale.

The spirochaetal agent of relapsing fever (*Borrelia recurrentis*).

The following Gram-negative micro-organisms:

Haemophilus ducreyi (chancroid).

Pasteurella pestis and *Pasteurella tularensis*.

Bartonella bacilliformis.

Bacteroides species.

Vibrio comma and *Vibrio fetus*.

Brucella species (in conjunction with streptomycin).

Because many strains of the following groups of micro-organisms have been shown to be resistant to tetracyclines, culture and susceptibility testing are recommended.

Terramycin is indicated for treatment of infections caused by the following Gram-negative micro-organisms, when bacteriological testing indicates appropriate susceptibility to the drug:

Escherichia coli.

Enterobacter aerogenes.

Shigella species.

Mima species and *Herellea* species.

Haemophilus influenzae (respiratory infections).

Klebsiella species (respiratory and urinary infections).

Terramycin is indicated for treatment of infections caused by the following Gram-positive micro-organisms when bacteriological testing indicates appropriate susceptibility to the drug:

Streptococcus species.

Diplococcus pneumoniae.

Staphylococcus aureus. (Skin and soft tissue infections).

When penicillin is contra-indicated, tetracyclines are alternative drugs in the treatment of infections due to:

Neisseria gonorrhoeae.

Treponema pallidum and *Treponema pertenue* (syphilis and yaws).

Listeria monocytogenes.

Clostridium species.

Bacillus anthracis.

Fusiformis fusiformis (Vincent's infection).

Actinomyces species.

In acute intestinal amoebiasis, the tetracyclines may be a useful adjunct to amoebicides. In severe acne, the tetracyclines may be useful adjunctive therapy.

Tetracyclines are indicated in the treatment of trachoma, although the infectious agent is not always eliminated, as judged by immunofluorescence.

Inclusion conjunctivitis may be treated with oral tetracyclines or with a combination of oral and topical agents.

Dosage and administration Oral administration.

Adults: The suggested minimum adult dosage for Terramycin is 1 g daily in divided doses given as 250 mg four times a day. Higher doses, such as 500 mg four times daily, may be required for severe infections or for those infections which do not respond to the smaller dose.

Children: Usual daily dose 25–50 mg/kg (10–20 mg/lb) of body weight divided in four equal doses.

Therapy should be continued for at least 24–48 hours after symptoms and fever have subsided.

Antacids containing aluminium, calcium or magnesium impair absorption and should not be given to patients taking oral tetracyclines.

Food and some dairy products also interfere with absorption. Oral forms of tetracyclines should be given one hour before or two hours after meals.

In patients with renal impairment: Total dosage should be decreased by reduction of recommended individual doses and/or by extending time intervals between doses.

In the treatment of streptococcal infections, a therapeutic dose of Terramycin should be administered for at least 10 days.

For treatment of brucellosis, 500 mg Terramycin four times daily accompanied by streptomycin.

Gonococcal infections: Male and female, 1.5 g initially followed by 0.5 g q.i.d. for a total of 9 g.

For treatment of syphilis, a total of 30–40 g in equally divided doses over a period of 10–15 days should be given. Close follow-up, including laboratory tests, is recommended.

Terramycin Ophthalmic Ointment with Polymyxin B Sulphate: (sterile): Terramycin Ophthalmic Ointment with Polymyxin B Sulphate is indicated for topical application in the prophylaxis and treatment of superficial ocular infections due to susceptible organisms. Topical application of Terramycin should be supplemented by systemic administration when infections are likely to become systemic.

Terramycin Ophthalmic Ointment with Polymyxin B Sulphate should be applied only topically as follows:

A small quantity (about 1 cm) of the ointment should be applied to the conjunctival sac of the lower lid four to six times daily until the infection is cleared and healing is complete. This may take from one day to several weeks depending on the nature and severity of the infection. In blepharitis, scales and crusts should be removed before applying medication.

For prophylaxis the same procedure is followed on the day before operation and subsequently for several days following it.

Trachoma: Terramycin Ophthalmic Ointment with Polymyxin B Sulphate may be used for the treatment of trachoma as follows:

The ointment should be applied three to six times daily, usually for 10 to 15 days in acute cases, while in chronic cases treatment should continue for up to three months. Careful follow-up is advised and if relapse occurs, a second course of treatment should be instituted.

Contra-indications, warnings, etc

Contra-indications: Terramycin is contra-indicated in persons who have shown hypersensitivity to any of the tetracyclines.

Warnings: The use of drugs of the tetracycline class during tooth development (last half of pregnancy, infancy and childhood to the age of eight years) may

cause permanent discoloration of the teeth (yellow-grey-brown). This adverse reaction is more common during long term use of the drugs but has been observed following repeated short-term courses. Enamel hypoplasia has also been reported. Tetracycline drugs, therefore, should not be used in this age group unless other drugs are not likely to be effective or are contra-indicated.

If renal impairment exists, even usual oral or parenteral doses may lead to excessive systemic accumulation of the drug and possible liver toxicity. Under such circumstances, lower than usual total doses are indicated and, if therapy is prolonged, serum level determinations of the drug may be advisable.

The antianabolic action of the tetracyclines may cause an increase in BUN. While this is not a problem in those with normal renal function, in patients with significantly impaired renal function, higher serum levels of tetracycline may lead to azotaemia, hyperphosphataemia and acidosis.

Photosensitivity manifested by an exaggerated sunburn reaction has been observed in some individuals taking tetracyclines.

As with other antibiotic preparations, Terramycin may result in overgrowth of nonsusceptible organisms, including fungi. If superinfection occurs, the antibiotic should be discontinued and appropriate therapy instituted.

In venereal diseases when coexistent syphilis is suspected a dark field examination should be performed before treatment is started and the blood serology repeated monthly for at least four months.

Because tetracyclines have been shown to depress plasma prothrombin activity, patients who are on anticoagulant therapy may require downward adjustment of their anticoagulant dosage.

In long-term therapy, periodic laboratory evaluation of organ systems, including hematopoietic, renal and hepatic studies should be performed.

All infections due to Group A beta-haemolytic streptococci should be treated for at least 10 days.

Since bacteriostatic drugs may interfere with the bactericidal action of penicillin, it is advisable to avoid giving tetracyclines in conjunction with penicillin.

Use in pregnancy: Results of animal studies indicate that tetracyclines cross the placenta, are found in foetal tissues and can have toxic effects on the developing foetus (often related to retardation of skeletal development). Evidence of embryotoxicity has also been noted in animals treated early in pregnancy.

Use in newborns, infants and children: All tetracyclines form a stable calcium complex in any bone forming tissue. A decrease in the fibula growth rate has been observed in prematures given oral tetracycline in doses of 25 mg/kg every six hours. This reaction was shown to be reversible when the drug was discontinued.

Tetracyclines are present in the milk of lactating women who are taking a drug in this class.

Adverse reactions: Gastro-intestinal: Anorexia, nausea, vomiting, diarrhoea, glossitis, dysphagia, enterocolitis and inflammatory lesions (with monilial overgrowth) in the anogenital region. These reactions have been caused by both the oral and parenteral administration of tetracyclines.

Skin: Maculopapular and erythematous rashes. Exfoliative dermatitis has been reported but is uncommon. Photosensitivity.

Renal toxicity: Rise in BUN has been reported and is apparently dose related.

(See 'Warnings'.)

Hypersensitivity reactions: Urticaria, angioneurotic oedema, anaphylaxis, anaphylactoid purpura, pericarditis and exacerbation of systemic lupus erythematosus.

Blood: Haemolytic anaemia, thrombocytopenia, neutropenia and eosinophilia have been reported.

Other: Bulging fontanels have been reported in young infants following full therapeutic dosage. This sign disappeared rapidly when the drug was discontinued.

When given over prolonged periods, tetracyclines have been reported to produce brown-black microscopic discoloration of thyroid glands. No abnormalities of thyroid function studies are known to occur.

Pharmaceutical precautions Store in a cool dry place. Protect from light.

Legal category POM.

TERRA-BRON* SYRUP

Presentation Each 5 ml of Terra-Bron Syrup contains 250 mg oxytetracycline as the calcium salt. Ephedrine Hydrochloride BP 7.5 mg and Ipecac. Liq. Ext. BP 0.03 ml.

Uses Terra-Bron combines the antimicrobial properties of Terramycin* (brand of oxytetracycline) together with the bronchodilator action of ephedrine hydrochloride and the expectorant properties of Ipecac Liq. Ext.

Terra-Bron is specifically formulated for the treatment of bronchitis requiring a combination of a wide-spectrum antibiotic with a bronchodilator and an expectorant. The spectrum of activity of Terramycin against a wide range of micro-organisms usually found in respiratory infections, supports the use of this antibiotic in the management of bronchitis. Activity of Terramycin against *H. influenzae* and pneumococci particularly indicates its use in chronic cases where these organisms are so often responsible for acute exacerbations. In patients with bronchial constriction, the bronchodilator effect of ephedrine will relieve spasm in the bronchial tree, ease dyspnoea and facilitate expectoration. Ipecac. Liq. Ext. has expectorant properties and those patients who have difficulty in clearing the bronchial tree of sputum will derive benefit from the stimulation of bronchial secretion and liquefaction of sputum.

Dosage and administration *Adults:* One 5 ml spoonful every six hours.

To achieve full antibiotic therapeutic effect, Terra-Bron should be taken without interruption. It should not be used irregularly as an ordinary cough medicine.

To aid the oral absorption of the drug, it should be given at least one hour before or two hours after meals. Aluminium hydroxide gel given with antibiotics has been

shown to decrease their absorption and should be avoided.

Contra-indications, warnings, etc

Contra-indications: Oxytetracycline tends to accumulate in the body in the presence of renal failure. Terra-Bron is therefore contra-indicated in patients with renal failure.

Precautions: As with all antibiotics, use of this preparation may result in overgrowth of nonsusceptible organisms, including fungi. If super-infection occurs, medication should be discontinued and appropriate specific therapy should be instituted.

As with other antibiotics, side-effects such as glossitis, stomatitis, proctitis, diarrhoea, vaginitis, due to modification of the gastro-intestinal or local microbial flora have been reported, but are rare.

Reactions due to allergy or individual idiosyncrasy including phototoxicity rarely occur. If adverse reactions, individual idiosyncrasy, or allergy occur, medication should be discontinued. It is contra-indicated in individuals who have shown hypersensitivity to it.

Oxytetracycline may form a stable calcium complex in any bone forming tissue. However, use of this antibiotic during tooth development (last half of pregnancy, neonatal period and early childhood) may cause discolouration of the teeth (yellow-grey-brownish). This effect occurs mostly during long-term use, but it has also been observed in usual short treatment courses.

Ephedrine hydrochloride may cause tachycardia and palpitations, but this is unlikely to occur with Terra-Bron therapy in normal doses. Ephedrine should not be given to patients suffering from ischaemic heart disease, cardiac decompensation, hypertension, hyperthyroidism or prostatic hypertrophy.

Uses in children: Terra-Bron is not indicated for use in children.

Overdosage: *Ephedrine:* Overdosage of ephedrine hydrochloride may cause tachycardia and/or arrhythmias, which if severe may require intravenous administration of beta-blocking agents under ECG control.

Ipecacuanha Liquid Extract: Overdosage with ipecacuanha is unlikely since high doses cause vomiting.

Oxytetracycline: Acute overdosage with antibiotics is rare.

Toxic effects are usually due to hypersensitivity reactions and should be treated as such.

Pharmaceutical precautions Store in a cool place. Shake well before use.

Legal category POM.

Package quantities Terra-Bron Syrup is available in bottles of 150 ml.

Further information Nil.

Product licence number 0057/5035

TERRA-CORTIL* EAR SUSPENSION

Presentation Terra-Cortril Ear Suspension contains 15 mg of Hydrocortisone Acetate BP, 5 mg of Oxytetracycline as the Hydrochloride BP and 10,000 units of polymyxin B sulphate in each millilitre of a controlled-viscosity, gel-like base.

Uses *Actions:* This single preparation provides a potent anti-inflammatory, anti-allergic hormone which controls

excessive tissue reaction to infections, allergens and trauma, and effective antibiotic activity to curtail the growth of the causative and secondary infecting organism(s).

The broad antimicrobial spectrum of oxytetracycline commends its use in the treatment of infections due to staphylococci, streptococci, pneumococci, *H. influenzae* (Koch-Weeks bacillus), the diplo-bacillus of Morax-Axenfeld, Friedlander's bacillus, *E. coli*, and *A. aerogenes*. The effectiveness of oxytetracycline against both Gram-positive and Gram-negative organisms is enhanced by the particular potency of polymyxin B against infections caused by Gram-negative organisms, especially those due to *Pseudomonas pyocyanea*, (*B. pyocyaneus*), where polymyxin B is the antibiotic of choice.

Indications: Terra-Cortril Ear Suspension is recommended for the topical treatment of ear conditions in which hydrocortisone is indicated and where there is the possibility of presence of infection by organisms sensitive to the tetracyclines or polymyxin B.

Terra-Cortril Ear Suspension is recommended for infections of the external ear canal due to organisms sensitive to the tetracyclines, particularly those of mixed bacterial origin and where the aetiology remains obscure and which are accompanied by inflammatory reactions for which hydrocortisone is indicated. The suspension is also recommended in the treatment of impetigo, diffuse otitis externa and for localised lesions which have become super-infected.

In addition, Terra-Cortril Ear Suspension may be used in allergic external otitis of mixed origin, atopic external otitis, excessive inflammatory reactions, pruritus and chronic eczema of the external ear canal.

If the infection is found to be deep-seated or spreading, the topical effect of the suspension should be reinforced by the systemic administration of Terramycin.

Dosage and administration For the treatment of affections of the external ear canal it is recommended that two to four drops be instilled three times daily, or as prescribed by the physician. The patient should be instructed to avoid contamination of the nozzle with exudate from the infected site.

Contra-indications, warnings, etc

Contra-indications: Terra-Cortril is contra-indicated in the presence of fungal infections. Acute purulent infections may be masked or enhanced by the presence of the steroid.

The use of topical hydrocortisone preparations is contra-indicated in tuberculous lesions of the skin, herpes simplex, vaccinia and varicella.

Hypersensitivity to any of the components of the preparation.

Warnings: Specific antimicrobial therapy by the systemic route is indicated for treatment of deep infections of the ear.

Precautions: Allergic reactions to oxytetracycline may occur occasionally, but are rare. If such reactions occur, the use of Terra-Cortril Ear Suspension should be discontinued.

The use of oxytetracycline and other antibiotics may result in an overgrowth of resistant organisms – particularly monilia and staphylococci. Constant observation of the patient for this possibility is required. If new infections due to non-susceptible bacteria or fungi appear during therapy, appropriate measures should be taken.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development.

The relevance of this to human beings has not been established. Topical steroids should not be used extensively in the first trimester of pregnancy, i.e. in large amounts or for prolonged periods. However, the unproven theoretical teratogenic hazard must be placed in perspective against the need for corticosteroids to maintain the health of the patient.

Caution should be exercised in the use of topical steroids in the treatment of infantile eczema because of the risk of suppression of adrenal function following absorption. To date this effect has not been reported with Terra-Cortril Ear Suspension.

Overdosage: Terra-Cortril Ear Suspension is unlikely to be taken by mouth. Systemic absorption from topical application is unlikely.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Tube 5 ml.

Further information The tube has a specially designed narrow nozzle.

Product licence number 0057/5073.

TERRA-CORTRIL* SPRAY

Presentation Terra-Cortril Spray contains Oxytetracycline Hydrochloride PhEur and Hydrocortisone PhEur in a finely divided form as a pressure packed presentation for topical application when both anti-inflammatory and anti-infective action is required. Terra-Cortril Spray is available as an aerosol in:

42 g (30 ml) container (50 mg hydrocortisone PhEur and 150 mg oxytetracycline as the hydrochloride PhEur).
84 g (60 ml) container (100 mg hydrocortisone PhEur and 300 mg oxytetracycline as the hydrochloride PhEur).

Uses Terramycin (oxytetracycline) is a potent broad-spectrum antibiotic which is useful topically for prevention or treatment of superficial cutaneous infections.

Cortril (hydrocortisone) is an adrenocortical steroid with excellent anti-inflammatory action at the tissue level. The topical application of this hormone in inflammatory dermatoses results in subsidence of erythema, oedema and pruritus without producing systemic effects.

Conditions in which Terra-Cortril Spray may be indicated include:

Atopic dermatitis including allergic eczema, disseminated and circumscribed neurodermatitis, pruritus with lichenification, eczematoid dermatitis, food eczema and infantile eczema.

Contact dermatitis due to plants, drugs, detergents, cosmetics, clothing material and miscellaneous substances.

Non-specific pruritus of the anus, vulva or scrotum.

Varicose eczema

Bed sores

Burns caused by chemicals and wet or dry heat.

In the allergic dermatoses the inciting allergens should be determined and eliminated where possible. In patients with widespread dermatitis of allergic origin, oral steroid therapy may be advisable. Supplemental therapy with an oral antibiotic is recommended in the treatment of severe infections.

Dosage and administration The area to be treated

should be cleansed, if possible. The spray should be applied three or four times daily, depending upon the severity of the condition being treated. Application may be made every two hours for severe conditions and decreased in frequency as a therapeutic response is obtained. Care should be taken not to discontinue therapy too soon after the initial response has been obtained.

Terra-Cortril Spray is for external use only. Do not spray into the eyes.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to any of the components of the preparation,

Acute herpes simplex, vaccinia and varicella.

Tuberculous lesions of the skin.

Fungal diseases of the skin.

Warnings: When used on the face, the eyes should be closed and protected.

Inhalation of the spray should be avoided.

Topical administration of corticosteroids to pregnant animals cause abnormalities of foetal development. The relevance of this to human beings has not been established. Topical steroids should not be used extensively in the first trimester of pregnancy, i.e., in large amounts or for prolonged periods. However, the unproven theoretical teratogenic hazard must be placed in perspective against the need for corticosteroids to maintain the health of the patient.

Caution should be exercised in the use of topical steroids in the treatment of infantile eczema because of the risk of suppression of adrenal function following absorption. To date this effect has not been reported with Terra-Cortril Spray.

Precautions: the use of Terramycin (oxytetracycline) and other antibiotics may result in an overgrowth of resistant organisms, particularly monilia and staphylococci. Constant observation of the patient for this possibility is required. If new infections due to non-susceptible bacteria or fungi appear, appropriate measures should be taken.

Overdosage: Terra-Cortril Spray is used topically and is unlikely to be taken by mouth. Systemic absorption from topical application is unlikely. (But see above.)

Pharmaceutical precautions Store in a cool place. The container must not be exposed to heat.

Legal category POM.

Package quantities 42 g (30 ml) aerosol.

84 g (60 ml) aerosol.

Further information Nil.

Product licence number 0057/5074.

TERRA-CORTRIL* TOPICAL OINTMENT

Presentation Terra-Cortril Topical Ointment contains Terramycin (oxytetracycline hydrochloride equivalent to 30 mg of oxytetracycline), and 10 mg of Cortril (hydrocortisone) in each gram of petroleum base.

Uses **Actions:** Cortril (hydrocortisone) is the natural adrenocortical steroid and has excellent anti-inflammatory activity at tissue level.

The topical application of this hormone in inflammatory dermatoses (infections, allergic, traumatic) results in the prompt subsidence of erythema, oedema, and pruritus, without producing systemic effects.

Terramycin is a potent broad spectrum antibiotic which is useful topically for the prevention or treatment of superficial cutaneous infections due to a variety of pyogenic bacteria, both Gram-positive and Gram-negative.

In the treatment of superficial infections of the skin amenable to Terramycin therapy, the anti-inflammatory action of the Cortril in this ointment affords prompt symptomatic relief while the Terramycin is acting against the causative organisms.

Similarly, where topical therapy with Cortril is desirable, the added presence of Terramycin will serve to prevent or eradicate secondary bacterial complications. Since varying degrees of bacterial infection frequently complicate those skin conditions for which Cortril topical therapy is indicated, this combined preparation may offer therapeutic advantages over the use of Cortril alone.

Terra-Cortril Topical Ointment is thus useful in the treatment of skin conditions in which antibacterial and anti-inflammatory effects are desired.

Supplementary therapy with oral Terramycin is advised in the treatment of severe infections or those which become systemic.

Indications: *Cutaneous infections:* Including superficial pyogenic infections, pyoderma, pustular dermatitis and infections associated with minor burns or wounds (under close supervision).

Atopic dermatitis: Including allergic eczema, both disseminated and circumscribed neurodermatitis, pruritus with lichenification, eczematoid dermatitis, food eczema and infantile eczema.

Contact dermatitis: Due to plants, drugs, cosmetics, clothing material and miscellaneous substances.

Non-specific pruritus of the anus, vulva or scrotum.

Dosage and administration After thorough cleansing of the affected skin areas, a small amount of the ointment should be applied gently. Applications should be made two to four times daily. When infection is present, the ointment may be applied on sterile gauze and, by this means, kept in continuous contact with the affected area. Care should be taken not to discontinue therapy too soon after the initial response has been obtained.

Contra-indications, warnings, etc

Contra-indications: Acute herpes simplex, vaccinia and varicella.

Tuberculosis of the skin.

Hypersensitivity to any of the components of the preparation.

Precautions: The use of Terramycin (oxytetracycline hydrochloride) and other antibiotics may result in an overgrowth of resistant organisms particularly monilia and staphylococci. Observation of the patient for this possibility is required.

Although Cortril and Terramycin are well tolerated, allergic reactions may occur occasionally, but are rare. If such a reaction occurs, Terra-Cortril Topical Ointment should be discontinued.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in the first trimester of pregnancy, i.e. in large amounts or for prolonged periods. However, the unproven theoretical teratogenic hazard must be

placed in perspective against the need for corticosteroids to maintain the health of the patient.

Caution should be exercised in the use of topical steroids in the treatment of infantile eczema because of the risk of suppression of the adrenal function following absorption. To date this has not been reported with Terra Cortril Ointment.

Terra-Cortril Topical Ointment is not recommended for ophthalmic use.

Overdosage: Terra-Cortril Topical Ointment is unlikely to be taken by mouth. Systemic absorption from topical application is unlikely. (But see above.)

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities 15 g tube.
30 g tube.

Further information Nil.

Product licence number 0057/5076.

TERRA-CORTIL* NYSTATIN CREAM

Presentation Terra-Cortril Nystatin Cream is a homogeneous yellow cream containing 30 mg Terramycin (oxytetracycline as calcium dioxycycline), 10 mg Cortril (hydrocortisone) and 100,000 units of nystatin in each gram of perfumed cream.

Uses Actions: Cortril (hydrocortisone) is the natural adrenocortical steroid and has excellent anti-inflammatory activity at tissue level. The topical application of this hormone in inflammatory dermatoses (infectious, allergic, traumatic) results in the prompt subsidence of erythema, oedema and pruritus, without producing systemic effects.

Terramycin (oxytetracycline) is a potent broad-spectrum antibiotic which is useful topically for the prevention or treatment of superficial cutaneous infections due to a variety of pyogenic bacteria, both Gram-positive and Gram-negative.

Nystatin is an antifungal agent active against *Candida albicans*, *Coccidioides immitis*, *Cryptococcus neoformans*, *Histoplasma capsulatum*, some *Blastomyces* and *Sporotrichum* species and yeasts.

In Terra-Cortril Nystatin Cream, these three effects are combined in one preparation.

Indications: Terra-Cortril Nystatin Cream is indicated in the treatment of steroid-responsive dermatoses. The added presence of oxytetracycline and nystatin will serve to prevent or eradicate secondary bacterial and fungal complications. Since varying degrees of bacterial and/or fungal infection frequently complicate those skin conditions for which hydrocortisone topical therapy is indicated, this combined preparation may offer therapeutic advantages over the use of hydrocortisone alone.

Among these conditions are:

Atopic dermatitis: Including allergic eczema, both disseminated and circumscribed neurodermatitis, pruritus with lichenification, eczematoid dermatitis, food eczema and infantile eczema.

Contact dermatitis: Due to plants, drugs, cosmetics, clothing material and miscellaneous substances.

Non-specific pruritus of the anus, vulva or scrotum.

Varicose eczema

Dosage and administration After thorough cleansing of the affected skin area, a small amount of the cream should be applied gently. Applications should be made two to four times daily. When infection is present the cream may be applied on sterile gauze and, by this means, kept in continuous contact with the affected area. Care should be taken not to discontinue therapy too soon after the initial response has been obtained.

Supplementary therapy with oral Terramycin is advisable in the treatment of severe infections or those which may become systemic.

Terra-Cortril Nystatin Cream can be used in infants, children and adults. Terra-Cortril Nystatin Cream is not recommended for ophthalmic use.

Contra-indications, warnings, etc

Contra-indications: Acute herpes simplex, vaccinia and varicella.

Tuberculosis of the skin.

Hypersensitivity to any of the components of the cream.

Precautions: The use of Terramycin (oxytetracycline) and other antibiotics may result in an overgrowth of resistant organisms particularly monilia and staphylococci. Observation of the patient for this possibility is required.

Although Cortril, Terramycin and nystatin are well tolerated, allergic reactions may occur occasionally, but are rare. If such a reaction occurs, Terra-Cortril Nystatin Cream should be discontinued.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in the first trimester of pregnancy i.e. in large amounts or for prolonged periods. However, the unproven theoretical teratogenic hazard must be placed in perspective against the need for corticosteroids to maintain the health of the patient.

Caution should be exercised in the use of topical steroids in the treatment of infantile eczema because of the risk of suppression of the adrenal function following absorption. To date this effect has not been reported with Terra-Cortril Ointment which contains the same concentration of hydrocortisone as does Terra-Cortril Nystatin Cream.

Overdosage: Terra-Cortril Nystatin Cream is unlikely to be taken by mouth. Systemic absorption from topical application is unlikely. (But see above.)

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities 30 g tube.

Further information Nil.

Product licence number 0057/0099.

VIBRAMYCIN*

Presentation Vibramycin is available as: green capsules containing 100 mg doxycycline as the hydrochloride, coded 'Pfizer' on the cap and 'VBM100' on the body.

Vibramycin-D (dispersible) tablets: off white-beige tablets marked D-7 on the one side and 'Pfizer' on the other each containing 100 mg doxycycline as the monohydrate and flavoured with blackcurrant.

Sup: 30 ml (5 ml containing the equivalent of 50 mg oxytetracycline as the calcium chelate), coloured red and fruit flavoured.

Vibramycin brand of doxycycline is a broad-spectrum antibiotic synthetically derived from oxytetracycline. The chemical designation of this light yellow crystalline powder is alpha-6-deoxy-5-oxytetracycline.

Vibramycin has a high degree of lipid solubility and low affinity for calcium. It is highly stable in normal human serum. Vibramycin will not degrade into an anhydrous form.

Uses: **Actions:** Vibramycin is primarily bacteriostatic and is believed to exert its antimicrobial effect by the inhibition of protein synthesis. Vibramycin is active against a wide range of Gram-positive and Gram-negative bacteria and certain other micro-organisms.

Tetracyclines are readily absorbed and are bound to plasma proteins in varying degrees. They are concentrated by the liver in the bile and excreted in the urine and faeces at high concentrations and in a biologically active form. Vibramycin is virtually completely absorbed after oral administration. Studies reported to date indicate that the absorption of Vibramycin, unlike certain other tetracyclines, is not notably influenced by the ingestion of food or milk.

Following a 200 mg dose, normal adult volunteers averaged peak serum levels of 2.6 mcg/ml of Vibramycin 2 hours decreasing to 1.45 mcg/ml at 24 hours. Studies have shown no significant difference in serum half-life of Vibramycin (range 18 to 22 hours) in individuals with normal and severely impaired renal function.

Haemodialysis does not alter the serum half-life of vibramycin.

Indications: Vibramycin has been found clinically effective in the treatment of a variety of infections caused by susceptible strains of Gram-positive and Gram-negative bacteria and certain other micro-organisms.

Pneumonia: Single and multilobe pneumonia and bronchopneumonia due to susceptible strains of *Pneumococcus* and other *Streptococcus* species, *Staphylococcus* species, *H. influenzae*, *Klebsiella pneumoniae*, and *Mycoplasma pneumoniae* (Eaton agent, PPL0).

Other respiratory tract infections: Pharyngitis, tonsillitis, titis media, bronchitis and sinusitis caused by susceptible strains of beta-haemolytic *streptococci*, *Staphylococcus* species, *pneumococci* and *H. influenzae*.

Genito-urinary tract infections: Pyelonephritis, cystitis, urethritis, caused by susceptible strains of the *Klebsiella-Enterobacter* group, *Escherichia coli*, *Staphylococcus* species, *Neisseria gonorrhoeae*, and *Chlamydia trachomatis*. Acute gonococcal anterior urethritis in the adult male has been effectively treated with a single large dose of Vibramycin. The highest cure rates were achieved with more extended therapy.

Soft tissue infections: Impetigo, furunculosis, cellulitis, abscess, infected traumatic and postoperative wounds and paronychia caused by susceptible strains of *Staphylococcus aureus*, *Staphylococcus albus*, *Streptococcus* species, *E. coli*, and susceptible strains of the *Klebsiella-Enterobacter* group. In the treatment of soft tissue infections, indicated surgical procedures should be carried out in conjunction with Vibramycin treatment.

Since Vibramycin is a member of the tetracycline series of antibiotics, it may be expected to be useful in the treatment of infections which respond to other tetracyclines, such as:

Ophthalmic infections: Due to susceptible strains of *gonococci*, *staphylococci*, and *H. influenzae*. Vibramycin is indicated in the treatment of trachoma, although the infectious agent is not always eliminated, as judged by immunofluorescence. Inclusion conjunctivitis may be treated with oral Vibramycin alone or in combination with topical agents.

Gastro-intestinal infections: Due to susceptible strains of such organisms as *Entamoeba histolytica*, enteropathogenic *E. coli*, *Shigella* species, and *Salmonella* species.

Miscellaneous: Psittacosis. Prostatitis and trigonitis due to *Proteus* species. Other infections due to susceptible strains of *Bacteroides* species, *Yersinia* species, *Brucella* species (in combination with streptomycin), *Listeria* species, *Rickettsia* species and *Bordetella pertussis*, *Bacillus anthracis*, *Clostridium welchii*, *Neisseria meningitis*, *spirochaetes* (*Treponema* species), *Calymmatobacterium granulomatis*.

Vibramycin may be useful in the treatment of acne vulgaris and acne conglobata.

In acute intestinal amoebiasis Vibramycin may be a useful adjunct to amoebicides.

Dosage and administration The usual dose of Vibramycin in adults is 200 mg on the first day of treatment (administered as a single dose or divided into two equal doses with a 12 hour interval), followed by a maintenance dose of 100 mg/day. In the management of more severe infections (particularly chronic infections of the urinary tract), 200 mg daily should be given throughout the treatment period. Vibramycin-D tablets are administered by drinking a suspension of the tablet in half a cup of water.

The recommended dosage schedule for children weighing 50 kg or less is 4 mg/kg of body weight on the first day of treatment (given as a single dose or divided into two equal doses with a 12 hour interval), followed by 2 mg/kg of body weight on subsequent days. For more severe infections up to 4 mg/kg of body weight may be used daily. For children over 50 kg the usual adult dose should be used. (See 'Warnings' section about use in children).

Administration of adequate amounts of fluid along with capsule forms of drugs in the tetracycline class is recommended to reduce the risk of oesophageal irritation and ulceration.

If gastric irritation occurs, it is recommended that Vibramycin be given with food or milk. Studies indicate that the absorption of Vibramycin is not markedly influenced by simultaneous ingestion of food or milk.

Exceeding the recommended dosage may result in an increased incidence of side-effects. Therapy should be continued at least 24 to 48 hours after symptoms and fever have subsided. When used in streptococcal infections, therapy should be continued for 10 days to prevent the development of rheumatic fever or glomerulonephritis.

Acute gonococcal anterior urethritis in males: A single dose of 300 mg or 100 mg b.i.d. for two to four days. The dose should be administered with food, including milk or carbonated beverage, as required.

Acute gonococcal infections in the adult female: Doses of 100 mg b.i.d. until cure is effected.

Primary and secondary syphilis: 300 mg a day in divided doses for at least 10 days.

Louse-borne typhus has been successfully treated with a single oral dose of 100 to 200 mg according to severity.

Concomitant therapy: antacids containing aluminium, calcium or magnesium impair absorption and should not be given to patients taking Vibramycin.

Studies to date have indicated that administration of Vibramycin at the usual recommended doses does not lead to excessive accumulation of the antibiotic in patients with renal impairment.

Contra-indications, warnings, etc

Contra-indications: Vibramycin is contra-indicated in persons who have shown hypersensitivity to any of the tetracyclines.

Warnings: The use of drugs of the tetracycline class during tooth development (last half of pregnancy, infancy and childhood to the age of 8 years) may cause permanent discoloration of the teeth (yellow-grey-brown). This adverse reaction is more common during long term use of the drugs but has been observed following repeated short term courses. Enamel hypoplasia has also been reported.

Photosensitivity manifested by an exaggerated sunburn reaction has been observed in some individuals taking tetracyclines. Patients likely to be exposed to direct sunlight or ultraviolet light should be advised that this reaction can occur with tetracycline drugs and treatment should be discontinued at the first evidence of skin erythema.

The antianabolic action of the tetracyclines may cause an increase in BUN. Studies to date indicate that this does not occur with the use of Vibramycin in patients with impaired renal function.

Use in pregnancy: (See 'Warnings' section about use during tooth development).

Vibramycin has not been studied in pregnant patients. It should not be used in pregnant women unless, in the judgement of the physician, it is essential for the welfare of the patient.

Results of animal studies indicate that tetracyclines cross the placenta, are found in foetal tissues and can have toxic effects on the developing foetus (often related to retardation of skeletal development). Evidence of embryotoxicity has also been noted in animals treated early in pregnancy.

Use in children: (See 'Warnings' section about use during tooth development).

As with other tetracyclines, Vibramycin forms a stable calcium complex in any bone-forming tissue. A decrease in the fibula growth rate has been observed in premature infants given oral tetracycline in doses of 25 mg/kg every 6 hours. This reaction was shown to be reversible when the drug was discontinued.

Tetracyclines are present in the milk of lactating women who are taking a drug of this class.

Precautions: The use of antibiotics may occasionally result in over-growth of nonsusceptible organisms. Constant observation of the patient is essential. If a resistant organism appears, the antibiotic should be discontinued and appropriate therapy instituted.

When treating gonorrhoea when coexistent syphilis is suspected proper diagnostic procedures, including dark-field examinations, should be utilized. In all such cases monthly serological tests should be made for at least four months.

Infections due to group A beta-haemolytic streptococci should be treated for at least 10 days.

Because the tetracyclines have been shown to depress plasma prothrombin activity, patients who are on anti-coagulant therapy may require downward adjustment of their anticoagulant dosage.

Since bacteriostatic drugs may interfere with the bactericidal action of penicillin, it is advisable to avoid giving Vibramycin in conjunction with penicillin.

Adverse reactions: Due to virtually complete absorption of Vibramycin gastro-intestinal side effects are infrequent. The following adverse reactions have been reported: **Gastro-intestinal:** anorexia, nausea, vomiting, diarrhoea, glossitis, dysphagia, enterocolitis, and inflammatory lesions (with monilial overgrowth) in the anogenital region. These reactions have been caused by both the oral and parenteral administration of tetracyclines. Rare instances of oesophagitis and oesophageal ulceration have been reported in patients receiving capsule form of drugs in the tetracycline class. Most of these patients took medications immediately before going to bed.

Skin: maculopapular and erythematous rashes. Exfoliative dermatitis has been reported but is uncommon. Photosensitivity is discussed in the 'Warnings' section.

Hypersensitivity reactions: urticaria, angioneurotic oedema, anaphylaxis, anaphylactoid purpura, pericarditis and exacerbation of systemic lupus erythematosus.

Bulging fontanelles have been reported in young infants following full therapeutic dose. This sign disappeared rapidly when the drug was discontinued.

Blood: haemolytic anaemia, thrombocytopenia, neutropenia and eosinophilia have been reported with tetracyclines.

When given over prolonged periods, tetracycline have been reported to produce brown-black microscopic discoloration of thyroid tissue. No abnormalities of thyroid function are known to occur.

Overdose and toxic effects: Acute overdosage with antibiotics is rare.

Toxic effects are usually due to hypersensitivity reactions and should be treated as such.

Pharmaceutical precautions Store in a cool place. Protect from light.

When Vibramycin Syrup is dispensed to meet prescriptions for 2.5 ml (25 mg) doses, the product should be diluted with an equal amount of simple syrup. This ensures that each 25 mg dose is taken in the minimum statutory volume of 5 ml. When thus dispensed the syrup should be used within 14 days.

Legal category POM.

Package quantities 100 mg capsules (green) in blister packs of 10 and 50.
Syrup 30 ml bottle (50 mg/5 ml.)
Dispersible tablets 100 mg in blister packs of 10.

Further information Nil.

Pharmaceutical Manufacturing Company

10 St. Peters House, 2 Bricket Road,
10 St. Albans, Hertfordshire AL1 3JW

YLOTOX* 2% E80

Presentation Injection in 1.8 ml and 2.2 ml cartridges.
Each ml contains:

lignocaine Hydrochloride PhEur 24.7 mg (equivalent to
20.0 mg of lignocaine base).
adrenaline BP 12.5 mcg.

Uses For the induction of local anaesthesia by infiltration
or nerve block injection.

Dosage and administration The dose required
depends on the condition of the patient and the area to
be anaesthetised and should be determined by the clinician
on an individual basis. Suggested doses are:

infiltration 0.5–2 ml

Nerve Block 1.5–2 ml

for extensive surgical procedures 3–10 ml

The maximum safe dose of lignocaine for a 70 kg (11
stone) man may be considered to be 500 mg in a solution
with a vasoconstrictor and is contained in 25 ml of
Ylotox 2% E80. Adherence to this maximum will also
ensure that the maximum dose of adrenaline (500 mcg)
is not exceeded. The number of cartridges used should
not exceed 14 × 1.8 ml or 11 × 2.2 ml.

Contra-indications, warnings, etc Xylotox 2% E80
should not be used where there is a known hypersensi-
tivity to local anaesthetics of the amide type, or where
the patient is taking tricyclic antidepressants. Care
should be taken (by correct technique) to avoid intra-
arterial injection, or injection into inflamed areas, and
in all cases injections must be performed slowly. Caution
required in patients with epilepsy, reduced hepatic or
renal function, or with impaired cardiac conduction.

The systemic effect of the vasoconstrictor may be
potentiated if the patient has thyrotoxicosis, is receiving
treatment with MAOI's, certain antihypertensive drugs,
or during general anaesthesia. Adequate facilities for
resuscitation should always be available.

Should toxic effects occur, they may take the form of
drowsiness, muscular twitching, respiratory depression,
convulsions and circulatory collapse.

Emergency treatment:

1. Prevent anoxia by ensuring a free airway and giving
oxygen.

2. Treat circulatory failure by raising the legs and
administering plasma expanders or pressor drugs which
should be given very cautiously to patients taking
tricyclic or MAOI antidepressants.

3. Control convulsions by intravenous injections of
5–10 mg of diazepam given slowly over 1 minute; or
intramuscular injection of paraldehyde 10 ml; or sodium
phenobarbitone 50–200 mg.

Pharmaceutical precautions Store in a cool dark
place. Partly used cartridges should be discarded.

Legal category POM.

Package quantities 100 × 2.2 ml
100 × 1.8 ml

Further information Nil.

Product licence number 0104/0066.

CALMURID*

Presentation A white shiny cream containing Carbamide (urea) BP 10% in a stabilising emulsified base.

Uses For correction of hyperkeratosis and dryness in ichthyosis and allied conditions characterised by dry, rough, scaly skin.

Dosage and administration A thick layer of Calmurid is applied twice daily after washing the affected area. The cream is left on the skin for three to five minutes and then lightly rubbed in. Excess cream can be wiped off with a tissue. Frequency of application can be reduced as patient progresses. In hyperkeratosis of the feet apply Calmurid as above after soaking the feet in warm water for 15 minutes and drying with a rough towel.

Contra-indications, warnings, etc *Adverse effects:* Calmurid is acidic and can cause smarting when applied to raw areas, fissures or mucous membranes. Where this is a barrier to therapy, use of Calmurid diluted 50% with Aqueous Cream BP for one week should result in freedom from smarting on application of Calmurid.

Pharmaceutical precautions Store in a cool place but do not freeze. Do not put in alloy containers.

Legal category GSL.

Package quantities Tubes of 50 g, 100 g and 300 g.

Further information Calmurid, besides being keratolytic, replaces the small water-binding molecules of which dry skin may be deficient. It does not contain lanolin, steroids or preservatives.

Product licence number 0009/5009.

CALMURID* HC

Presentation A white shiny cream containing:

Carbamide (urea) BP 10%
Hydrocortisone 1%

in a stabilising emulsified base.

Uses Atopic eczema; Besnier's prurigo; acute and chronic allergic eczema; neurodermatitis and other hyperkeratotic skin conditions with accompanying inflammation.

Dosage and administration Apply the cream twice daily.

Contra-indications, warnings, etc *Adverse effects:* Because Calmurid HC is acidic it may cause smarting if applied to raw or fissured areas. Moist lesions should be encouraged to dry before beginning therapy.

Where smarting is a barrier to therapy, use of a mixture of Calmurid HC with an equal amount of Aqueous Cream BP for a week should result in freedom from smarting when undiluted Calmurid HC is applied.

In pregnant animals, administration of corticosteroid can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for long periods.

In infants, long-term continuous topical therapy should be avoided. Adrenal suppression can occur even without occlusion.

Pharmaceutical precautions Keep in a cool place but do not freeze. Do not pack in alloy containers.

Legal category POM.

Package quantities Tubes of 30 g and 100 g.

Further information Calmurid HC has keratolytic, antipruritic, anti-inflammatory and re-hydrating effect on the skin. It does not contain lanolin or preservatives.

Product licence number 0009/5003.

DEBRISAN*

Presentation Sterile, straw-coloured spherical bead of dextranomer of 0.1–0.3 mm diameter, packed in plastic castors or single-use sachets.

Uses A dressing for moist wounds and indolent ulcers, whether clean or infected and small area burns.

Dosage and administration A 3 mm layer of Debrisan should be sprinkled onto the wound and kept in place by a pad of lint or a perforated plastic sheet. Debrisan is hydrophilic and the tissue exudate is drawn up into the layer. The Debrisan should be renewed before saturation occurs. Depending on the rate of exudation this may be necessary from one to five times a day. Once or twice daily is usually adequate. When Debrisan is changed the old material is readily rinsed off with water or saline and new material may then be sprinkled onto the wound.

Shallow wounds, or those in awkward positions, may be dressed more easily by mixing four parts of Debrisan with one part of sterile glycerol to form a stiff paste. This should be spread into the wound with a spatula to a depth of 3 mm or more. Dressing continues as above. The paste should be prepared freshly at each application.

Full instructions for use are enclosed with each pack. Treated in this manner the wound will remain soft and pliable during healing.

Contra-indications, warnings, etc

1. Do not leave Debrisan for more than 24 hours or wounds with a very low exudation rate as it may dry and form a crust which may be difficult to wash off.

2. Occlusive dressings may lead to maceration of skin round the wound under treatment.

3. When deep infected wounds are treated, care must be taken to wash Debrisan from the depths of the wound.

4. No side-effects have been reported.

Warning: Debrisan spillage can render surfaces very slippery. Clear spillages promptly.

Precautions:

1. Not to be used on dry wounds.
2. When exudate has been markedly removed by Debrisan alternative treatment should be substituted.
3. In order to avoid cross-infection it is recommended that the contents of a castor be confined to the treatment of a single patient for one day.

Pharmaceutical precautions Keep in a dry place in well-closed containers.

Package quantities Castors of 60 g.
Sachets of 4 g in boxes of ten sachets.

Legal category POM.

Further information Each gram of Debrisan absorbs 4 grams of exudate. Capillary action carries debris and bacteria away from the wound surface. Local oedema is reduced so that the wound may look larger initially. Debrisan is non sensitising and controls malodour. Once wound is clean and poorly secreting change therapy to an antiseptic dressing, e.g. chlorhexidine tulle, or a sterile pad.

Product licence number 0009/0021.

HEALONID* ▼

Presentation Disposable single-use syringes containing 0.4 ml Healonid of the following composition per ml:

Sodium hyaluronate	10 mg
Sodium chloride	8.5 mg
Disodium hydrogen phosphate dihydrate	0.28 mg
Sodium dihydrogen phosphate hydrate	0.04 mg
Water for injections	to 1 ml

The syringe membrane must be perforated before use, (see directions for use).

Uses Sodium hyaluronate is a visco-elastic polymer normally found in the aqueous and vitreous humour. Healonid, which contains sodium hyaluronate is a highly viscous clear solution at rest, yet it will readily flow through a fine cannula or needle under pressure. Introduction of Healonid into the anterior or posterior chamber keeps tissues separated during the operative procedure and protects them from trauma from other tissues or instruments. The anterior chamber depth is maintained, vitreous bulge can be reduced, and the loss of irreplaceable endothelial cells which inevitably accompanies surgery can be greatly reduced.

Indications: Surgical procedures on the eye, including intraocular lens insertion, intra and extra capsular lens extraction, glaucoma surgery, corneal graft, surgery for accidental trauma, retinal detachment and vitreal replacement procedures.

Dosage and administration The syringe is assembled and made ready for use according to the instruction sheet with each syringe.

Cataract surgery: A sufficient volume of Healonid is gently introduced into the anterior chamber at an early stage in the operation prior to lens extraction to protect the tissues from trauma.

Intraocular lens insertion: Healonid is introduced into the anterior chamber before lens extraction and is also used to coat the lens and instruments prior to introduction

into the eye. Further Healonid may be injected to replace losses.

Glaucoma filtration surgery: Prior to trabeculectomy Healonid is injected slowly through a corneal paracentesis to maintain the anterior chamber volume. Injection may be continued to allow Healonid to flow through the sutured outer scleral flap to the conjunctival filtration site.

Corneal transplant surgery: After removal of the corneal button the anterior chamber is filled with Healonid. The donor graft is then placed on the bed of Healonid and sutured into place. Healonid may be put into the anterior chamber of the donor eye to protect the corneal endothelium.

Trauma: In various kinds of perforating trauma Healonid can be instilled to refill the anterior chamber, prevent prolapse of the iris and formation of synechiae. Blood contaminated Healonid should be replaced with new Healonid before closure.

Precautions: The anterior chamber should not be over-filled with Healonid, except in glaucoma surgery. At close of surgery some of the Healonid should be removed by irrigation or aspiration. Intraocular pressure should be monitored during the post operative period and any excessive rises treated with appropriate therapy.

Contra-indications, warnings, etc There are no known contra-indications to Healonid. Because the drug is extracted from avian tissues, despite rigorous purification procedures minute amounts of protein are present, and thus the remote possibility of idiosyncratic reactions remains.

Adverse reactions: The drug is very well tolerated and the only untoward effect reported has been a transient rise in intraocular pressure in a few cases.

Pharmaceutical precautions Store at 2–8°C protected from light and freezing. Shelf life 3 years.

Legal category POM.

Package quantities Disposable syringes containing 0.4 ml.

Further information Healonid does not interfere with the healing process. Its use may reduce incidence of synechiae and adhesions. Evidence from animal experiments indicates that Healonid is no longer present in the anterior chamber six days after introduction.

Product licence number 0009/0045.

MACRODEX* IN DEXTROSE

Presentation Macrodex in Dextrose contains:

Dextran of weight average molecular weight	
70,000	30 g
Dextrose	25 g
Water for Injections	to 500 ml

Colourless, clear, slightly viscous solution. Bottle has a yellow seal.

Uses

1. As a plasma volume expander.
2. The prevention of thrombo-embolic episodes.
3. As a low sodium content alternative to Macrodex in Normal Saline.

Dosage and administration Dose may be adjusted to the needs and progress of the case.

Hypovolaemic shock: Give 500–1,000 ml i.v. as initial dose, the rate dependent on the patient's needs. Thereafter give equal volumes of Macrodex and blood. Haematocrit should be kept above 25%. Total Macrodex dose should not exceed 2,500 ml.

Shock prophylaxis at surgery: 500–1,000 ml is run in during operation, the rate being governed by pulse, skin colour, BP, etc.

Burns: Use to correct haemoconcentration. In general 3–5 litres can be given daily for 48 hours.

Prophylaxis of post-operative thrombosis: Slowly infuse 500 ml during or at the end of surgery over four to six hours, followed by a further 500 ml over four to six hours next day. In high-risk cases (hip fractures, history of thrombosis, etc.) continue the treatment on alternate days for up to two weeks.

Contra-indications, warnings, etc. Precautions: Give with caution to patients vulnerable to vascular overloading (congestive heart failure, renal disease, etc.).

Adverse reactions: Very rarely spontaneous hypersensitivity – urticaria, rigors and flushing, occasionally with asthma and hypotension. Usually occurs in cases not under stress and appears within a few minutes of starting the infusion. **Action:** Stop the infusion and give symptomatic anti-allergic therapy.

Pharmaceutical precautions Store at steady room temperature. Poor storage can produce dextran flakes, which can be re-dissolved by autoclaving.

Legal category POM.

Package quantities Infusion bottles of 500 ml.

Further information Nil.

Product licence number 0009/5001.

MACRODEX* IN NORMAL SALINE

Presentation Macrodex in Normal Saline contains:

Dextran of weight average molecular weight	
70,000	30 g
Sodium Chloride	4.5 g
Water for Injections	to 500 ml

Colourless, clear, slightly viscous solution. Bottle has a green seal.

Uses

1. As a plasma volume expander.
 2. The prevention of thrombo-embolic episodes.
 3. In certain cases of renal or cardiac disease
- Macrodex in 5% Dextrose may be preferred for its low sodium content.

Dosage and administration Dose may be adjusted to the needs and progress of the case.

Hypovolaemic shock: Give 500–1,000 ml i.v. as initial dose, the rate dependent on the patient's needs. Thereafter give equal volumes of Macrodex and blood. Haematocrit should be kept above 25%. Total Macrodex dose should not exceed 2,500 ml.

Shock prophylaxis at surgery: 500–1,000 ml is run in during operation, the rate being governed by pulse, skin colour, BP, etc.

Burns: Use to correct haemoconcentration in general 3 litres can be given daily for 48 hours.

Prophylaxis of post-operative thrombosis: Slowly infuse 500 ml during or at the end of surgery over four to six hours, followed by a further 500 ml over four to six hours, next day. In high-risk cases (hip fractures, history of thrombosis, etc.) continue the treatment on alternate days for up to two weeks.

Contra-indications, warnings, etc. Give with caution to patients vulnerable to vascular overloading (congestive heart failure, renal disease, etc.). Where a sodium load is undesirable, use Macrodex in 5% Dextrose.

Adverse reactions: Very rarely spontaneous hypersensitivity – urticaria, rigors and flushing, occasionally with asthma and hypotension. Usually occurs in cases not under stress and appears within a few minutes of starting the infusion. **Action:** Stop the infusion and give symptomatic anti-allergic therapy.

Pharmaceutical precautions Store at steady room temperature. Poor storage can produce dextran flakes, which can be re-dissolved by autoclaving.

Legal category POM.

Package quantities Infusion bottles of 500 ml.

Further information Nil.

Product licence number 0009/5000.

PERFUDEX*

Presentation Infusion bottle of 1 litre containing:

Dextran, weight average	
Molecular weight 40,000	50 g
NaCl	8.0 g
KCl	0.4 g
Na ₂ HPO ₄ ·7H ₂ O	0.0875 g
KH ₂ PO ₄	0.0625 g
MgSO ₄ ·7H ₂ O	0.2 g
Dextrose	1.0 g
Water for Injections	to 1,000 ml
Osmolarity:	295 mOs.

Uses As a basic wash-through and preservation fluid in the transplantation of organs.

Procedure Perfudex at 2–5°C is run into the artery of the organ as soon as possible after death. Procaine, heparin, penicillin, etc. may be added as desired. Perfusion should be continued until the venous outflow is clear. Procedure beyond this point varies according to the organ.

Warning Perfudex is not intended for use as an infusion in living subjects.

Pharmaceutical precautions Store at a steady temperature. Do not freeze. Check compatibilities of additives with the ions in the solution.

Legal category POM.

Package quantities Bottles of 1 litre.

Further information Perfudex is used principally in kidney transplantation.

Product licence number 0009/5010.

RELAXIT*

Presentation A sterile viscous solution contained in a 5 ml applicator pack.

Relaxit contains:

Sodium citrate (dihydrate)	450 mg
Sodium lauryl sulphate	75 mg
Sorbic acid	5 mg
Glycerol and Sorbitol Solution to	5 ml

Uses Relaxit in a micro-enema for the relief of constipation.

Dosage and administration *Adults and children over the age of three:* The nozzle of the micro-enema is inserted fully into the rectum and the contents squeezed out.

Children under the age of three: Insert only half the length of the nozzle then squeeze the contents out.

Contra-indications, warnings, etc None.

Pharmaceutical precautions Store in a cool place. Shelf life two years.

Legal category P.

Package quantities Boxes of 4 or 100.

Further information Relaxit liberates bound water in the faecal mass, thus producing a soft motion which may be easily evacuated. Defaecation usually occurs within 15 minutes.

Product licence number 0009/0019.

RHEOMACRODEX* IN DEXTROSE

Presentation Rheomacrodex 10% in 5% Dextrose contains:

Dextran 40	50 g
Dextrose	25 g
Water for Injections	to 500 ml

It complies with the monograph for Dextran 40 Injection BP. The solution is clear and slightly viscous. The infusion bottle has a red seal.

Uses

1. As a plasma volume expander.
2. To counteract diminution of the blood flow in the circulatory system.
3. The prevention and management of thrombotic episodes.
4. As a low sodium content alternative to Rheomacrodex in Normal Saline.

Dosage and administration Adjust dosage to needs and progress of the case.

1. Adults

Reduced capillary circulation in shock, etc: 500–1,000 ml i.v. over 30–60 minutes, with further 500 ml later same day. Thence 500 ml/day for up to five days.

Impaired arterial or venous circulation: Initially 500–1,000 ml i.v. over four to six hours. Give 500 ml next day, then alternate days for up to two weeks.

Prophylaxis of post-operative thrombosis: Infuse 500 ml i.v. during or at the end of surgery followed by 500 ml given over four to six hours next day. In high-risk cases (hip fractures, history of thrombosis etc) continue the infusions, giving 500 ml over four to six hours alternate days for up to two weeks.

Vascular and plastic surgery: 500 ml i.v. immediately before surgery over 30–60 minutes with another 500 ml given during the operation. A further 500 ml over four to six hours is given post-operatively and on alternate days for up to two weeks.

Open cardiovascular surgery: 10–20 ml per kg body weight is added to perfusion fluid. Concentration of dextran should never exceed 3%.

2. Children

Infants: 5 ml/kg body weight.

Children: 10 ml/kg body weight.

Contra-indications, warnings, etc

Contra-indications: Severe bleeding tendency, e.g. thrombocytopenia. Severe congestive cardiac failure. Established renal failure with anuria.

Precautions:

1. Correct existing dehydration in patients before giving Rheomacrodex. Give adequate fluids during therapy (keep urine flow above 250 ml/6 hours, Urine SG below 1.065).
2. Extra care with patients vulnerable to vascular overloading (congestive heart failure, renal failure).
3. If Rheomacrodex is given with heparin, reduce heparin dose by 35–70% because of synergism.

Adverse reactions:

1. Very rarely spontaneous hypersensitivity as urticaria, rigors and flushing, occasionally with asthma and hypotension. Usually occurs in cases not under stress and appears within a few minutes of starting the infusion.
- Action:** Stop the infusion and give symptomatic therapy.
2. Capillary oozing of wound surfaces due to improved perfusion pressure and capillary flow.

Pharmaceutical precautions Store at steady room temperature. Poor storage can produce dextran flakes. These re-dissolve on autoclaving.

Legal category POM.

Package quantities Infusion bottles of 500 ml.

Further information Nil.

Product licence number 0009/5005.

RHEOMACRODEX* IN NORMAL SALINE

Presentation Rheomacrodex 10% in Normal Saline contains:

Dextran 40	50 g
Sodium Chloride	4.5 g
Water for Injections	to 500 ml

It complies with the monograph for Dextran 40 Injection BP. The solution is clear and slightly viscous. The infusion bottle has a blue seal.

Uses

1. As a plasma volume expander.
2. To counteract diminution of blood flow in the circulatory system.
3. The prevention and management of thrombotic episodes.

In certain cases of renal or cardiac disease where an additional sodium load is undesirable Rheomacrodex 10% in 5% Dextrose may be preferred.

Dosage and administration Adjust dosage to needs and progress of the case.

1. Adults

Reduced capillary circulation in shock, etc: 500–1,000 ml i.v. over 30–60 minutes, with further 500 ml later same day. Thence 500 ml/day for up to five days.

Impaired arterial or venous circulation: Initially 500–1,000 ml i.v. over four to six hours. Give 500 ml next day, then alternate days for up to two weeks.

Prophylaxis of post-operative thrombosis: Infuse 500 ml i.v. during or at the end of surgery followed by 500 ml given over four to six hours next day. In high risk cases (hip fractures, history of thrombosis, etc) continue the infusions, giving 500 ml over four to six hours alternate days for up to two weeks.

Vascular and plastic surgery: 500 ml i.v. immediately before surgery over 30–60 minutes with another 500 ml given during the operation. A further 500 ml over four to six hours is given post-operatively and on alternate days for up to two weeks.

Open cardiovascular surgery: 10–20 ml per kg body weight is added to perfusion fluid. Concentration of dextran should never exceed 3%.

2. Children

Infants: 5 ml/kg body weight.

Children: 10/kg body weight.

Contra-indications, warnings, etc

Contra-indications: Severe bleeding tendency, e.g. thrombocytopenia. Severe congestive cardiac failure. Established renal failure with anuria.

Precautions:

1. Correct existing dehydration in patients before giving Rheomacrodex. Give adequate fluids during therapy (keep urine flow above 250 ml/6 hours, Urine SG below 1.065).

2. Extra care with patients vulnerable to vascular overloading (congestive heart failure, renal failure). Rheomacrodex in 5% Dextrose may be preferred in these cases.

3. If Rheomacrodex is given with heparin, reduce heparin dose by 35–70% because of synergism.

Adverse reactions:

1. Very rarely spontaneous hypersensitivity as urticaria, rigors and flushing, occasionally with asthma and hypotension. Usually occurs in cases not under stress and appears within a few minutes of starting the infusion. **Action:** Stop the infusion and give symptomatic anti-allergic therapy.

2. Capillary oozing of wound surfaces due to improved perfusion pressure and capillary flow.

Pharmaceutical precautions Store at steady room temperature. Poor storage can produce dextran flakes. These re-dissolve on autoclaving.

Legal category POM.

Package quantities Infusion bottle of 500 ml.

Further information Nil.

Product licence number 0009/5004.

SALAZOPYRIN*

Presentation *Plain tablets:* Yellow-brown, 13.5 mm diameter tablets, tasteless, scored deeply on one side containing sulphasalazine 0.5 g.

Film-coated enteric tablet: Rough-texture, yellow, ovoid film-coated tablet, 18 mm long × 10 mm broad × 6 mm maximum thickness. Each EN-tablet contains 0.5 g sulphasalazine.

Suppositories: Brown, odourless, torpedo-shaped (Type A2), containing sulphasalazine 0.5 g.

Enema: Soft plastic disposable enema bottles containing sulphasalazine 3 g, vehicle to 100 mls.

Uses In the induction and maintenance of remission in ulcerative colitis, distal proctocolitis, stump proctitis, Crohn's disease.

Dosage and administration The dose is adjusted according to the severity of the disease and the patient's tolerance to the drug. Rapid passage of the tablets may reduce effect of the drug. Night-time interval between doses should not exceed eight hours.

1. Plain tablets or EN tablets:

Adults: Severe attack: Salazopyrin tablets 2–4 four times a day may be used in conjunction with steroids as part of an intensive management regime.

Moderate attack: Give 2–4 tablets four times a day for two to three weeks. On remission, commence maintenance therapy.

Maintenance therapy: Gradually reduce the dose to 3–4 tablets per day. This dosage should be continued indefinitely since discontinuance even several years after the acute attack is associated with a four-fold increase in relapse risk.

Children: The dose is reduced in proportion to the body weight.

Acute attack or relapse: 40–60 mg/kg per day.

Maintenance dosage: 20–30 mg/kg per day.

2. Suppositories: Distal proctocolitis and stump proctitis.

Acute attack or relapse: Adults: 2 suppositories to be inserted in the morning and two at bedtime after defaecation. After three weeks gradually reduce the dosage as improvement occurs.

Adjuvant to oral therapy: In severe generalised ulcerative colitis affecting the rectum or rectosigmoid and cases slow to respond to oral therapy, 1–2 suppositories morning and evening may be given in addition.

Children: Reduce the adult dosage on the basis of body weight.

3. Enema: One enema should be given daily preferably at bedtime. This preparation contains an adult dose.

Administration: Patient instructions are enclosed in each box.

Contra-indications, warnings, etc

Contra-indications: Contra-indicated when there is a marked history of sensitivity to sulphonamides or salicylates. Infants under 2 years.

In the case of the enema, subjects sensitive to methyl or propyl parabens.

Adverse reactions: Since Salazopyrin is partly metabolised into sulphapyridine and 5-amino salicylic acid side-effects common to sulphonamides and salicylates may occur. Patients with slow acetylator phenotype are more likely to have adverse effects due to sulphapyridine. The most commonly encountered reactions are nausea, loss of appetite and raised temperature. Greater subdivision of the dose through the 24 hours, or use of the EN-tablets, enema, or suppositories may be beneficial.

If serious toxic or hypersensitivity reactions occur the drug should be discontinued immediately.

There is no specific antidote to Salazopyrin. Because ulcerative colitis also may affect the liver, joints, eyes, veins and skin, apparent adverse effects may be in fact an extension of the disease.

Salazopyrin may depress folate or digoxin uptake.

The drug may colour urine orange-yellow.

Rarely the following adverse reactions have been reported.

Haematological: Heinz body anaemia, methaemoglobinuria, hypoprothrombinaemia, haemolytic anaemia, leucopenia, agranulocytosis, aplastic anaemia, megaloblastic anaemia, thrombocytopenia.

Hypersensitivity reactions: Generalised skin eruptions, Stevens Johnson Syndrome, exfoliative dermatitis, epidermal necrolysis, pruritus, urticaria, photosensitisation, anaphylaxis, serum sickness syndrome, drug fever, periorbital oedema, conjunctival and scleral injection, arthralgia, allergic myocarditis, polyarteritis nodosa, LE-phenomenon and lung complications with dyspnoea, fever, cough, eosinophilia, fibrosing alveolitis.

Gastro-intestinal reactions: Nausea, loss of appetite, stomatitis, parotitis, pancreatitis, hepatitis and impaired folic acid absorption.

CNS reactions: Headache, vertigo, tinnitus, peripheral neuropathy, ataxia, convulsions, insomnia, mental depression and hallucinations.

Fertility: Oligospermia, reversible on discontinuance of drug.

Renal reactions: Crystalluria, haematuria, proteinuria and nephrotic syndrome.

As for other sulphonamides an acute attack in patients with porphyria may be precipitated.

Precautions: Blood checks should be made initially and periodically. They should also be made in the event of specific side-effects or vague symptoms such as lassitude. Allergic and renal or hepatic disease cases should be treated with caution. Patients with glucose-6-phosphate-dehydrogenase deficiency should be observed closely for signs of haemolytic anaemia.

Pregnancy and Lactation: While the ingestion of drugs in these situations may be undesirable, the severe exacerbations of the disease which can occur commends the continuance of therapy. Long clinical usage and experimental studies have failed to reveal teratogenic or icteric hazards. The amounts of drug present in the milk should not present a risk to a healthy infant.

Pharmaceutical precautions Store the suppositories in a cool place.

Legal category POM.

Package quantities *Plain Tablets:* Bottles of 100 and 500.

En Tablets: Bottles of 100 and 500.

Suppositories: Boxes of 10 and 50.

Enemas: Boxes of 7 × 100 ml.

Further information Nil.

SPRILON*

Presentation A 200 g aerosol spray contains: Dimethicone 1.2 g (Dimethicone 350 BPC 73% Dimethicone 200 BPC 27%). Zinc Oxide BP 14.4 g. Base to 60 g (wool fat, wool alcohols, cetyl alcohol, dextran, liquid paraffin, white soft paraffin and water). Propellants to 200 g (Dichlorofluoromethane BPC and Trichlorofluoromethane BPC.)

Uses For prophylaxis and treatment of pressure sores, skin maceration due to faeces or urine, or around fistulae and ileostomies. Protection and treatment of fissures, leg ulcers, moist eczemas. Protection of skin beneath plaster casts.

Dosage and administration Shake can well. Spray surface at right angles from distance of eight inches. Two to three seconds should be sufficient for an area the size of the buttocks.

Contra-indications, warnings, etc *Precautions:* Protect the eyes. Keep out of the reach of children. Do not use on cases allergic to wool fat.

Warning: Do not puncture, incinerate or heat can over 50°C even when empty.

Pharmaceutical precautions Nil.

Legal category GSL.

Package quantities 200 g.

Further information The spray rapidly forms a white, durable, flexible film which while protecting the skin and assisting healing also allows normal transepidermal water loss.

Product licence number 0009/5002.

PHARMALGEN® BEE VENOM (*Apis Mellifera*) ▼

Presentation 5 ml vials containing white freeze-dried material. When reconstituted with NSA-diluent (Pharmalgen) each 1 ml contains:

Venom	100 mcg
Normal Serum Albumin	0.3 mg
Mannitol	30 mg
Sodium Chloride	9.0 mg
Phenol	4.0 mg
Water for injections to	1 ml

Uses Diagnosis and treatment of allergy to bee stings.

Dosage and administration See package insert.

Contra-indications, warnings, etc

Contra-indications: Other serious immunological illness, infections and pregnancy. Pregnancy is not an absolute contra-indication but the risk to the foetus of an anaphylactic reaction must be considered.

Precautions:

1. Read instructions carefully before use.
2. Use as directed by a specialist.
3. Follow sterile procedure for injections. Use a disposable tuberculin syringe for subcutaneous injections.
4. Avoid intravascular injection: check by aspiration of the syringe.
5. Observe the patient for an hour after each injection, and have the means of treatment of possible anaphylactic reactions, (e.g. adrenaline) immediately available.

Pharmaceutical precautions Store refrigerated, at 2–8°C.

Shelf life is 3 years in freeze-dried condition for venoms, and 3 years for NSA diluent whilst sealed.

After reconstitution: solutions at concentrations down to 1.00 mcg/ml have a shelf life of 4 weeks at 2–8°C.

Precaution: The container permits the withdrawal of successive doses provided that adequate aseptic precautions are taken to ensure the maintenance of sterility of the product over the intended period of use.

Note: Do not re-freeze reconstituted venom.

Legal category POM.

Package quantities

Boxes of 4 vials of venom with 4 vials of NSA diluent for reconstitution.

Boxes of 10 vials of 4.5 ml NSA diluent for further dilution of venom.

Further information Patients desensitized with Pharmalgen will require monthly injections to maintain their protection. Regular investigations of venom specific IgE and IgG levels will indicate changes in their immunity, but at present treatment is recommended to continue for 3 years.

Product licence number Bee Venom, with NSA diluent 0009/0024.

PHARMALGEN® WASP VENOM (*Vespula spp*) ▼

Presentation 5 ml vials containing white freeze-dried material. When reconstituted with NSA-diluent (Pharmalgen) each 1 ml contains:

Venom	100 mcg
Normal Serum Albumin	0.3 mg
Mannitol	30 mg
Sodium Chloride	9.0 mg
Phenol	4.0 mg
Water for injections to	1 ml

Uses Diagnosis and treatment of allergy to wasp stings.

Dosage and administration See package insert.

Contra-indications, warnings, etc

Contra-indications: Other serious immunological illness, infections and pregnancy. Pregnancy is not an absolute contra-indication but the risk to the foetus of an anaphylactic reaction must be considered.

Precautions:

1. Read instructions carefully before use.
2. Use as directed by a specialist.
3. Follow sterile procedure for injections. Use a disposable tuberculin syringe for subcutaneous injections.
4. Avoid intravascular injection: check by aspiration of the syringe.
5. Observe the patient for an hour after each injection, and have the means of treatment of possible anaphylactic reactions, (e.g. adrenaline) immediately available.

Pharmaceutical precautions Store refrigerated, at 2–8°C.

Shelf life is 3 years in freeze-dried condition for venoms, and 3 years for NSA diluent whilst sealed.

After reconstitution: solutions at concentrations down to 1.00 mcg/ml have a shelf life of 4 weeks at 2–8°C.

Precautions: The container permits the withdrawal of successive doses provided that adequate aseptic precautions are taken to ensure the maintenance of sterility of the product over the intended period of use.

Note: Do not re-freeze reconstituted venom.

Legal category POM.

Package quantities

Boxes of 4 vials of venom with 4 vials of NSA diluent for reconstitution.

Boxes of 10 vials of 4.5 ml NSA diluent for further dilution of venom.

Further information Patients desensitized with Pharmalgen will require monthly injections to maintain their

protection. Regular investigations of venom specific IgE and IgG levels will indicate changes in their immunity, but at present treatment is recommended to continue for 3 years.

Product licence number Wasp Venom, with NSA diluent 0009/0025.

SPECTRALGEN® POLLENS (SINGLE SPECIES) ▼

Presentation Availability: Spectralgen Pollens are available for the diagnosis and treatment of allergy to grass pollens (Rye grass, Timothy, Rye (cultivated) and Velvet grass/Yorkshire Fog) and tree pollens (Grey Alder, Common Silver Birch, Hazel).

Mixtures of the four grass pollens or the three tree pollens are also available (see following Data Sheets).

Initial treatment sets: Each pack contains four vials of freeze dried allergen and four vials of diluent.

There is a ten-fold increase in potency from one vial to the next, a colour coding of the vial caps aiding identification. When the vials are each reconstituted with 4.5 ml of diluent they have the following composition per ml, ignoring the diluent solutes.

		Capped vial	*No.
Glycine	0.24 mg/ml		
Purified Pollen	100 BU*/ml	Green	1
Allergens	1,000 BU/ml	Yellow	2
	10,000 BU/ml	Red	3
	100,000 BU/ml	Brown	4

Maintenance treatment sets: Single vials of 10,000 BU/ml or 100,000 BU/ml are supplied with a vial of either NSA or Depot Diluent, as a kit for maintenance injections.

Each pack may be ordered with either Albumin (human) diluent or Depot diluent, according to intended procedure.

(1) Albumin (human) – suitable for diagnosis and all forms of therapy.

Each ml contains:

Normal Serum Albumin (Human)	0.3 mg
Sodium Chloride	9 mg
Phenol	4 mg

(2) Depot Diluent – suitable for conventional desensitization and maintenance. Each ml contains:

Sodium Chloride	9 mg
Phenol	5 mg
Aluminium Hydroxide corresponding to	
Aluminium Oxide	1.3 mg
Disodium EDTA	0.1 mg
Water for injections to	1 ml

Uses Diagnosis and treatment of allergy to grass or tree pollen.

Dosage and administration An initial treatment course can usually be completed in 3–12 weeks. For full details see package insert which gives conventional and semi-rush dosage schedules.

Contra-indications, warnings, etc

Contra-indications: Other serious immunological illness, infections and pregnancy. Pregnancy is not an absolute

contra-indication but the risk to the foetus of an anaphylactic reaction must be considered.

Precautions: (1) read the instructions carefully before use.

(2) Follow sterile procedure for injections. Use a disposable tuberculin syringe for subcutaneous injections.

(3) Do not inject into a blood vessel or muscle.

(4) Observe the patient for at least half an hour after each injection and have the means of treatment of possible anaphylactic reactions (e.g. adrenalin), immediately available.

(5) If drugs which modify the allergic response such as antihistamines or bronchodilators, have been given within the previous twenty-four hours the patient's tolerance of an allergen injection may be increased. A consistent policy with respect to concurrent medications should be followed.

(6) Other vaccines should not be given within seven days before or after an allergen injection.

(7) For use under medical supervision only.

(8) In order to avoid possible contamination it is advised that solutions, once made up, should be discarded after four hours. However, the containers do permit the withdrawal of successive doses provided that aseptic precautions are taken to maintain the sterility of the product over the intended period of use.

Pharmaceutical precautions: *Shelf-life:* The shelf-life of freeze dried Spectralgen pollen when protected from light, is three years at 2–8°C. The shelf-life of albumin and Depot diluent, sealed and protected from light, is three years at 2–8°C.

Spectralgen pollen preparations in solution (reconstituted) should be kept at 2–8°C and not frozen. At concentrations of 100 BU/ml and above, allergens in solution have a shelf-life of at least twelve weeks at 2–8°C.

Contents of vials should not be mixed with other preparations and materials should not be transferred to other vials, as stability would be adversely affected. Only Spectralgen diluents are suitable for reconstituting the freeze dried material.

Legal category POM.

Package quantities *Initial treatment set:* Each pack consists of four 5 ml colour coded allergen vials together with four 5 ml vials of the diluent requested (specify NSA or Depot diluent).

Maintenance treatment set: Each pack consists of one colour coded allergen vial (No. 3, 10,000 BU/ml or No. 4, 100,000 BU/ml as specified) with one vial of either NSA or Depot diluent.

Further information For *in vivo* testing and initial semi-rush or rush treatment dilution with albumin diluent is recommended. For maintenance treatment, the Depot diluent alternative may be used. See package insert for details. Treatment with Spectralgen is recommended only after a full specific allergy diagnosis has shown that the patient is allergic to the particular allergens, and that the condition is mediated by IgE, which can be verified by measuring specific IgE with Phadebas RAST. Additional vials of albumin diluent are routinely available.

Note: 1,000 biological units (BUs) are equivalent to one Histamine Equivalent Prick, 1 HEP) i.e. in a panel of known sensitive patients 1,000 BUs or one HEP will

give the same skin test reaction as a skin prick test with 0.1% Histamine chloride solution. This procedure is used to establish the allergenic potency of the reference material for each species, but for batch to batch quality control an inhibition RAST method is used.

SPECTRALGEN POLLENS (4 GRASS MIX) ▼

Presentation Availability: Spectralgen mixed grass pollens are available for the treatment of multiple allergy to grass pollen. The mixture contains purified pollen from allergens of four members of the Gramineae – Rye grass (*Lolium perenne*), Timothy grass (*Phleum pratense*), Cultivated Rye (*Secale cereale*), and Velvet grass/Yorkshire Fog (*Holcus lanatus*). Closely related grasses have allergens in common with those named above so the mixture induces tolerance to related species and these four species will cover all the important grasses found in Britain.

Diagnosis of allergy to specify species may be made by Phadebas RAST if the condition is IgE mediated or by *in vivo* testing with Spectralgen pollens individual species. The mixture may be used where no single species features dominantly in the diagnosis.

Initial treatment sets: Each pack contains four vials of freeze dried allergen and four vials of diluent.

There is a ten-fold increase in potency from one vial to the next, a colour coding of the vial caps aiding identification. When the vials are each reconstituted with 4.5 ml of diluent they have the following composition per ml, ignoring the diluent solutes.

Glycine 0.24 mg/ml

SPECTRALGEN* POLLENS (3 TREE MIX) ▼

Presentation Availability: Spectralgen mixed tree pollens are available for the treatment of multiple allergy to tree pollens. The mixture contains purified allergens from pollen of Grey Alder (*Alnus incana*), Common Silver Birch (*Betula verrucosa*), and Hazel (*Corylus avellana*). Closely related trees have allergens in common with those named above, so the mixture induces tolerance to related species.

Diagnosis of allergy to specific species may be made if the condition is IgE mediated by the Phadebas RAST test for those species or by *in vivo* testing with individual species. The mixture may be used where no single species features dominantly in the diagnosis.

Initial treatment sets: Each pack contains four vials of freeze dried allergen and four vials of diluent.

There is a ten-fold increase in potency from one vial to the next, a colour coding of the vial caps aiding identification. When the vials are each reconstituted with 4.5 ml of diluent they have the following composition per ml, ignoring the diluent solutes.

BEOGEX* SUPPOSITORIES

Presentation White evacuant suppositories available in adult and paediatric sizes. Each adult suppository contains:

Sodium Bicarbonate PhEur	1.08 g
Anhydrous sodium acid phosphate (equivalent to 1.72 g Sodium Acid Phosphate BP).	1.32 g

in an inert polyethylene glycol base

Each paediatric suppository contains:

Sodium Bicarbonate PhEur	0.7 g
Anhydrous sodium acid phosphate (equivalent to 0.91 g Sodium Acid Phosphate BP).	0.7 g

in an inert polyethylene glycol base

Uses Chronic simple constipation; constipation due to prolonged bed rest; constipation due to drugs.

Bowel evacuation before childbirth and surgery and prior to sigmoidoscopy and radiological examinations; bowel evacuation post-operatively to avoid discomfort associated with straining.

To regularise bowel movement and keep stools to normal consistency in local anal conditions such as haemorrhoids, fissures and fistulae.

Dosage and administration One suppository half an hour before evacuation is required. The suppository should be moistened with water, not lubricated with oil, before insertion into the rectum.

Contra-indications, warnings, etc No contra-indications except in conditions where any bowel medication for the relief of constipation is contra-indicated. No side-effects have been reported.

Pharmaceutical precautions Store in a dry place at room temperature.

Legal category GSL.

Package quantities

Adults: Box of 60 strip-packed suppositories.

Paediatric: Box of 6 strip-packed suppositories.

Further information The action of Beogex Suppositories commences on contact with water or moist mucous lining of the rectum. Carbon dioxide is liberated which causes gentle distension of the lower bowel, and thereby induces peristalsis.

Adults 0108/5001
 Children 0108/5002

COLOMYCIN* INJECTION

Presentation Colomycin Injection is Colistin Sulphomethate Injection BP presented as a neutral glass vial containing a creamy-white crystalline powder (before reconstitution). Available as:

1. Colistin Sulphomethate Sodium BP 500,000 units
2. Colistin Sulphomethate Sodium BP 1,000,000 units.

Uses Colomycin Injection is used in the treatment of systemic infections caused by sensitive Gram-negative organisms, e.g. in urinary tract infection, respiratory infection, meningitis, septicaemia, osteomyelitis.

Dosage and administration Colomycin Injection is usually administered intramuscularly or intravenously, but when indicated can be introduced via other routes such as intrathecally, subconjunctivally, by aerosol inhalation and by local instillation.

Normal recommendations for systemic treatment are:

Children (up to 60 kg): 50,000 units/kg/body weight in 24 hours, divided into three eight-hourly doses.

Adults (over 60 kg): 6,000,000 units in 24 hours (i.e. $2 \times 1,000,000$ unit vials every eight hours).

Infusion therapy: Daily dosage as above. Infusion, should preferably be completed within six hours.

Aerosol therapy: Daily dosage as above, concomitant with parenteral administration. For the aerosol, colistin is dissolved in water or saline for use in a suitable nebuliser attached to an air/oxygen supply.

Bladder irrigation: 1,000,000 units are dissolved in 50 ml water or saline and instilled during catheterisation. In the presence of infection, administration is carried out twice daily.

The above are expressed as average doses. Should clinical or bacteriological response be slow, dosage may be increased as indicated by the patient's condition. Minimum of five days treatment is recommended.

Where there is moderate or severe renal impairment, excretion of the antibiotic is delayed. Therefore, size of dose and dosage interval should be adjusted in relation to renal function. The table overleaf is a guide to dosage modifications in order to prevent accumulation of Colomycin. It is stressed that adjustments may still have to be made on evaluation of the individual patient.

Blood level estimations are recommended. 10–15 mcg/ml should be adequate.

Contra-indications, warnings, etc Colomycin Injection is contra-indicated in patients with known sensitivity to colistin. With appropriate dosage modifications, Colomycin need not be withheld in cases of renal impairment. Curariform muscle relaxants should be used with extreme caution in patients receiving Colomycin Injection.

Adverse reactions may include transient sensory disturbances such as perioral paraesthesia and vertigo. Therapy need not be discontinued and reduction of dosage may alleviate symptoms. Adverse effects on renal function have been reported but this generally returns to normal following discontinuation of therapy. Permanent nerve damage, such as deafness or vestibular damage,

<i>Creatinine clearance (ml/min)</i>	<i>B.U.N. (mg/100 ml)</i>	<i>(mmol/l)</i>	<i>Adult dosage</i>	<i>Childrens' dosage</i>
20–72	> 60	> 10	1½–2 million units every 8 hr	12,500–16,000 units/kg every 8 hr
10–20	> 100	> 16.5	1½ million units every 12–18 hr	12,500 units/kg every 12–18 hr
< 10	> 200	> 33	1 million units every 18–24 hr	8,000 units/kg every 18–24 hr

has not been reported. Local irritation at the site of injection is minimal.

Overdosage can result in renal insufficiency, muscle weakness and apnoea. There is no specific antidote; management is supportive treatment plus attempts to increase the rate of elimination of colistin, e.g. mannitol diuresis, prolonged haemodialysis, or peritoneal dialysis.

Pharmaceutical precautions Vials should be stored in a cool dry place protected from light. Solutions of Colomycin for parenteral administration should preferably be freshly prepared. Compatible infusion solutions are Normal Saline; 5% dextrose; 5% fructose; Ringer's solution; 10% Dextran 40 in Normal Saline. Infusions should be completed within six hours.

Mixed infusions or injections involving Colomycin should be avoided.

Colomycin Injection is compatible with the preservative phenylmercuric nitrate, and with the mucolytic agents acetylcysteine and superinone.

Legal category POM.

Package quantities Boxes of 10 × 500,000 unit vials and 10 × 1,000,000 unit vials.

Further information Colistin is a polypeptide antibiotic which possesses bactericidal activity against most Gram-negative organisms. Clinically it is of particular value in serious infections caused by pathogens such as *Pseudomonas aeruginosa*, *Escherichia coli*, *Klebsiella* spp. It cannot be recommended for *Proteus* spp.

Susceptible organisms do not readily develop or acquire resistance, and R factor mediated resistance has not been encountered.

(1 mg Colistin Sulphomethate Sodium is approx 12,500 units.)

Product licence numbers

500,000 units 0108/5005
1,000,000 units 0108/5006.

COLOMYCIN* TABLETS COLOMYCIN* SYRUP COLOMYCIN* STERILE POWDER

Presentation *Colomycin Tablets (Colistin Tablets BP)*: 1,500,000 unit tablet; white tablet with P in hexagon on one face and two crossed score-marks on reverse, containing Colistin Sulphate BP 1,500,000 units.

Syrup: Pale pink powder for reconstitution, containing Colistin Sulphate BP 4,000,000 units per bottle (i.e. 250,000 units/5 ml, when dispensed).

Sterile powder: White crystalline powder in neutral glass vial, containing: (a) Colistin Sulphate BP 1 g. (b) Colistin Sulphate BP 5 g.

Uses The treatment of gastro-intestinal infections

caused by sensitive Gram-negative organisms. Also bowel preparation. In addition, the sterile powder can be used for topical infections. Colistin Sulphate is not absorbed from the gastro-intestinal tract, and must *not therefore be used for systemic infections*.

Dosage and administration *Oral therapy (tablets, syrup or solution)*: Children up to 15 kg: 250,000–500,000 units (i.e. 5–10 ml syrup) every eight hours.

Children of 15–30 kg: 750,000–1,500,000 units every eight hours.

Adults, and children over 30 kg: 1,500,000–3,000,000 units every eight hours.

Minimum of five days treatment is recommended. Should clinical or bacteriological response be slow, dosage may be increased.

Bowel preparation: A 24-hour course of Colistin Sulphate at the normal dosage above. Treatment should preferably finish 12 hours before surgery.

Topically: Usually applied at a 1% concentration as a solution, powder or ointment, according to the nature of the infection.

COLOMYCIN STERILE POWDER MUST NOT BE USED FOR PREPARATION OF INJECTABLE SOLUTIONS.

Contra-indications, warnings, etc There are no absolute contra-indications to oral therapy, and side-effects are rare. The syrup base contains sucrose. In cases of intolerance a solution of Colomycin Sterile Powder can be used.

Topical therapy is well tolerated; transient irritation at the site of application has been reported infrequently. Allergic sensitisation has not occurred.

Pharmaceutical precautions Colomycin preparations should be stored in a cool dry place, protected from light.

After reconstitution with water, Colomycin Syrup is stable for two weeks at room temperature.

Suitable ointment bases for colistin with stability of one month at room temperature include Simple Cream BP; Simple Cream plus hydrous lanolin (90:10); Hydrous Ointment BP; Macrogol Ointment BPC.

For a topical powder, Colomycin can be dispensed with lactose or Biosorb.

Eye and ear drops can be made in water or saline, 0.002% phenylmercuric nitrate is a suitable preservative.

Topical solutions of Colistin can be stored for one month at room temperature.

Legal category POM.

Package quantities 1,500,000 units Tablet: Securitainers of 50 tablets.

Syrup: Bottle for reconstitution to 80 ml.

Sterile Powder: Vials of 1 g and 5 g.

Further information 1 mg Colistin Sulphate is approx. 9,500 units.

Suspension	0108/5008
Syrup	0108/5009
g and 5 g Sterile Powder	0108/5010

DIOVOL* SUSPENSION AND TABLETS

Presentation White mint flavoured suspension; yellow fruit flavoured suspension.

Each 5 ml contains:

Aluminium Hydroxide	
equivalent to dried gel BP	200 mg
Magnesium Hydroxide BP	200 mg
Dimethicone BPC	25 mg

Two Layer yellow/white mint-flavoured tablets containing:

Aluminium Hydroxide/Magnesium Carbonate	
Co-dried gel	300 mg
Magnesium Hydroxide BP	100 mg
Dimethicone BPC	25 mg

Uses Antacid/antiflatulent therapy in gastric and duodenal ulcer, gastritis, heartburn, gastric hyperacidity and Hiatus hernia. Treatment of indigestion, flatulence and abdominal distension due to entrapped gas.

Dosage and administration Usual adult doses are: 0–20 ml three times daily, preferably between meals and at bedtime, or as required. 1–2 tablets to be sucked or chewed as required.

Contra-indications, warnings, etc Diovol should not be used in patients who are severely debilitated or suffering from kidney failure. Antacids inhibit the absorption of tetracyclines and should not be taken concomitantly. Gastrointestinal side-effects are uncommon.

Pharmaceutical precautions Diovol tablets and suspension may be stored at room temperature.

Legal category GSL.

Package quantities *Suspension*: Bottles of 100 ml and 300 ml. *Tablets*: Packs of 50.

Further information Diovol is a pleasant-tasting well tolerated antacid containing equal quantities of Aluminium and Magnesium. This balanced formulation minimises the problems of diarrhoea or constipation.

Dimethicone is an effective antiflatulent which lowers the surface tension of gas bubbles present in the stomach, thus promoting eructation.

Both mint and fruit flavour suspensions are available.

Product licence numbers

Suspension	0203/5007 (Mint flavour)
	0108/0072 (Fruit flavour)

EFFICO* TONIC

Presentation Green-coloured syrup. Each 5 ml contains:

Thiamine Hydrochloride PhEur	0.18 mg
Caffeine PhEur	20.20 mg
Nicotinamide PhEur	2.10 mg
Compound Gentian Infusion BP	0.31 ml

Uses As a tonic and appetite stimulant during convalescence, especially in the aged.

Dosage and administration *Adults*: 10 ml immediately before meals, three times a day.

Children: 2.5–5 ml immediately before meals, three times a day.

If preferred, Effico can be diluted with water.

Contra-indications, warnings, etc There are no absolute contra-indications. Use should be avoided in diabetics.

Pharmaceutical precautions Store away from sunlight in a cool dry place.

Legal category GSL.

Package quantities Glass bottles of 300 ml and 2 litres.

Further information Nil.

Product licence number 0108/5013.

FLAVELIX*

Presentation Yellow elixir with citrus/menthol odour. Each 5 ml contains:

Mepyramine Maleate BP	12.5 mg
Ephedrine Hydrochloride PhEur	10.0 mg
Ammonium Chloride PhEur	90.0 mg
Sodium Citrate PhEur	40.0 mg

Uses As a combined expectorant, decongestant and bronchodilator for the treatment of coughs associated with the common cold, influenza, bronchial and pulmonary disorders, and also coughs aggravated by an allergic component.

Dosage and administration *Adults*: 10 ml taken orally three or four times daily. Not more frequently than four-hourly.

Children: 1–5 years: 2.5 ml.

5–10 years: 5.0 ml.

All three times daily.

Contra-indications, warnings, etc

Contra-indicated in the presence of coronary thrombosis, hypertension and thyrotoxicosis. Caution is required in patients with organic heart disease and those receiving digitalis.

It should not be administered to patients being treated with a monoamine oxidase inhibitor. Flavelix may cause drowsiness and patients should be advised against driving or operating machinery if affected. Side-effects from Flavelix are uncommon. Large doses may cause gastro-intestinal side-effects, headache, muscular weakness and CNS effects. In the event of severe toxicity, stomach aspiration and lavage may be required.

Pharmaceutical precautions Store at room temperature.

Legal category POM.

Package quantities Bottles of 150 ml and 2 litres.

Further information Mepyramine maleate is an antihistamine with comparatively low sedative effect and short duration of action. The combination with expectorant and bronchodilator activities is intended for the relief of productive cough and bronchial congestion.

Product licence number 0108/5014.

FLETCHERS' ARACHIS OIL RETENTION ENEMA

Presentation Ready-to-use, self-contained single-dose, disposable enema containing Arachis Oil BP 130 ml.

Uses To soften impacted faeces.

Dosage and administration *Adults:* 1 enema as required.

Children: In proportion, according to age.

The enema should be warmed before use.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store at room temperature.

Legal category P.

Package quantities Box of 10 × enemas.

Further information Nil.

Product licence number 0108/5016.

FLETCHERS' PHOSPHATE ENEMA

Presentation Fletcher's Phosphate Enema is Phosphate Enema BPC, Formula B, in a ready-to-use, self-contained, disposable, single-dose enema of 128 ml aqueous solution containing:

Sodium Acid Phosphate BP	12.80 g
Sodium Phosphate PhEur	10.24 g

Available with standard or long rectal tube.

Uses Routine treatment of constipation. Pre- and post-operative cleansing of the bowel, in obstetrics and prior to proctoscopy, sigmoidoscopy or X-ray examination.

Dosage and administration *Adults:* 1 enema, as required.

Children: In proportion, according to age.

The enema may be administered at room temperature, or warmed in warm water before use. The long-tube variety will provide better operating distance for staff and easier control for self-administration.

Contra-indications, warnings, etc Phosphate enemas should not be used in patients with increased absorptive capacity of the colon, e.g. Hirschsprung's disease. They should be used with caution in patients requiring reduced sodium intake. A check on electrolyte balance may be advisable during prolonged continuous therapy.

Pharmaceutical precautions Store in a cool place.

Legal category GSL.

Package quantities *Standard:* Box of 10 enemas; also box of 50 enemas.

Long Tube: Box of 10 enemas; also box of 50 enemas.

Further information Nil.

Product licence number 0108/5015.

HAYMINE*

Presentation Yellow sustained release tablet, marked on one side with 'P' inside a hexagon.

Each tablet contains:

Chlorpheniramine Maleate BP	10 mg
Ephedrine Hydrochloride PhEur	15 mg

Uses Relief of symptoms caused by allergic condition: such as hay fever, allergic rhinitis, perennial rhinitis, urticaria etc., which are responsive to antihistamines.

Dosage and administration *Adults and children over 12:* One tablet in the morning after rising. A further tablet may be taken at night if required. Not recommended for children under 12 years of age. Tablets should be swallowed whole, NOT CHEWED.

Contra-indications, warnings, etc Although the combination of ephedrine with the antihistamine chlorpheniramine is intended to reduce drowsiness, caution should still be employed when driving or operating machinery. Alcoholic drinks and certain other central nervous system depressants can potentiate any sedative effects.

Side-effects of ephedrine are rare at the low doses employed in this preparation. However, in particularly susceptible patients effects such as giddiness, palpitations and muscular weakness may be experienced transiently. The use of ephedrine is contra-indicated in the presence of coronary thrombosis, hypertension and thyrotoxicosis, or in patients being treated with a monoamine oxidase inhibitor.

Pharmaceutical precautions Can be stored at room temperature.

Legal category P.

Package quantities Packs of 10 and 30 strip packed tablets.

Further information The combination of ephedrine, which is a central nervous system stimulant, with chlorpheniramine maleate is designed to reduce the problems of drowsiness commonly experienced with antihistamine therapy.

Product licence number 0108/0054.

MEGACLOL* CAPSULES

Presentation Red, oblong, soft gelatin capsules containing Clomocycline Sodium 170 mg.

Uses Megaclo is a methylol derivative of chlortetracycline used in the treatment of infections caused by tetracycline-sensitive organisms, including infections associated with the genito-urinary tract, respiratory tract, ENT and soft tissue. It may also be used for specific infections such as brucellosis, and for long-term therapy in acne.

Dosage and administration *Adults:* 1 or 2 capsules three or four times daily. Suggested dosage for acne in adults is: 4 capsules daily for one week, 2 capsules daily for one week then 1 capsule daily for seven weeks, or maintenance as required.

Contra-indications, warnings, etc Tetracyclines are contra-indicated in severe renal or hepatic failure, or where there is a history of hypersensitivity to tetracyclines. Tetracycline may cause a yellow or brown discoloration of teeth in children or the developing foetus. For this reason it should be avoided during pregnancy, and in children where ever possible. Absorption of Megaclo may be impaired by concomitant administration of calcium, magnesium, iron or aluminium

alts (e.g. in antacids). Gastro-intestinal side-effects may occur, but are infrequent and seldom troublesome. Photosensitive reactions are uncommon. In the event of overdosage, employ gastric lavage and supportive therapy; there is no specific antidote.

Pharmaceutical precautions Store in a cool dry place and protect from light. Dispense in an airtight container.

Legal category POM.

Package quantities Securitainers of 100 capsules.

Further information Megaclo is highly soluble and is rapidly and almost completely absorbed from the small intestine.

Product licence number 0108/5020.

IVOL*

Presentation Yellow suspension. Each ml contains:
 Dicyclomine Hydrochloride BP 10 mg
 Dimethicone BPC 40 mg

Uses For the prevention and treatment of infant colic.

Dosage and administration *Infants:*
up to 6 months: 0.5 ml before feeds
 (Maximum daily dose 2 ml)
6–24 months: 0.5 to 1 ml before feeds.
 (Maximum daily dose 4 ml)

The Ovul bottle contains a graduated dropper unit for convenience of dosing. The suspension can be placed directly into the back of the mouth by dropper, or mixed with a small amount of food.

Contra-indications, warnings, etc Contra-indicated in patients with known sensitivity to the active ingredients. Contra-indicated in patients with, or suspected of having glaucoma. Symptoms of overdosage apparent in infants are dilated pupils, dry mouth, difficulty in swallowing and hot, dry skin. Side-effects seldom occur at the recommended dosage, but may include rash, constipation, anorexia, vomiting, dysuria and dyspnoea in addition to symptoms mentioned above.

Overdosage: May be treated with gastric lavage, emetics and activated charcoal. Barbiturates may be used either orally or intra-muscularly if sedation is required. Central and peripheral anticholinergic effects of dicyclomine overdosage may be controlled by subcutaneous injection of Physostigmine (1 mg per m² of body surface area) repeated at 30 minute intervals if necessary.

Pharmaceutical precautions Can be stored at room temperature.

Legal category P.

Package quantities Bottles of 15 ml.

Further information The combination of Dicyclomine and Dimethicone is designed to alleviate both spasm and flatulence in infant colic. Ovul is supplied as a concentrated suspension, in order that only the minimum volume necessary to carry the active ingredients need be administered to infants.

Product licence number 0203/0022.

PAEDO-SED*

Presentation Lemon-flavoured, pale straw-coloured syrup. Each 5 ml contains:

Dichloralphenazone BP 200 mg
 Paracetamol PhEur 100 mg

Uses Sedative, analgesic and antipyretic for the relief of pain, fever and restlessness in babies and children.

Dosage and administration

Up to 6 months 2.5 ml
 6–12 months 5.0 ml
 1–4 years 10.0 ml
 Over 4 years 15–20 ml

The above doses to be taken orally three or four times daily as required.

Contra-indications, warnings, etc Contra-indicated in cases of gastritis or in patients with known sensitivity to phenazone. Use with caution in patients with hepatic, renal or severe cardiac disease. Haematological reactions and skin eruptions may occur.

Overdosage may lead to nausea, fever, diarrhoea, vomiting, deep stupor, low blood pressure, respiratory depression, and liver and renal damage. The stomach should be emptied by aspiration and lavage; hypotension should be corrected and assisted respiration may be necessary. Haemodialysis may be required if renal failure occurs.

Pharmaceutical precautions Store in a cool place, protected from light. Can be diluted with orange juice, milk or other liquids if required.

Legal category POM.

Package quantities Bottles of 100 ml and 500 ml.

Further information Nil.

Product licence number 0108/5022.

PHASAL*

Presentation White sustained-release tablets marked on one side with 'P' inside a hexagon. Each Phasal tablet contains 300 mg Lithium Carbonate BP.

Uses Lithium is an antimanic agent, it can also exert a stabilising influence on recurrent affective disorders. Recommended uses:

1. Treatment of acute manic or hypomanic episodes.
2. Prophylaxis in manic-depressive disorders, recurrent mania or recurrent depression.

Dosage and administration Dosage may be adjusted in the individual patient according to clinical condition and the results of regular blood lithium determinations.

1. *Acute episode:* Initially 2 tablets b.d. Increase by 1 or 2 tablets per day if no response. Maintain blood lithium levels in the range 0.5–1.5 mmol. Dosage should be reduced rapidly once the initial attack subsides.

2. *Prophylaxis:* Usually 600–1,200 mg/day given in divided doses. Clinical improvement is usually associated with serum concentrations of 0.5 mmol or above. Toxic symptoms are usually associated with concentrations exceeding 1.5 mmol.

When starting directly on prophylactic therapy administer 2 tablets daily initially, with subsequent increments of 1 tablet until therapeutic blood levels are achieved.

Use in elderly: 500–1,000 mg/day given in divided doses. Toxic symptoms are likely with serum concentrations above 1.0 mmol.

Use in children: The use of lithium in children is not recommended.

Measurement of serum lithium concentrations. Lithium therapy should not be initiated unless adequate facilities for routine monitoring of serum concentrations are available. On initiation of therapy, serum concentrations should be measured weekly until stabilisation is achieved, then weekly for one month and at monthly intervals thereafter. Additional measurements should be made if signs of lithium toxicity occur (see below), on dosage alteration, development of significant intercurrent disease, signs of manic or depressive relapse and if significant change in sodium or fluid intake occurs. More frequent monitoring is required if patients are receiving diuretics. With Phasal maximum blood levels normally occur within two to four hours of dosing.

As bioavailability varies from product to product (particularly with regard to sustained-release preparations) a change of product should be regarded as initiation of new treatment. Blood levels should therefore be monitored weekly until re-stabilisation is achieved.

Tablets must be swallowed whole, NOT CHEWED.

Contra-indications, warnings, etc

Contra-indications: Renal or cardiovascular disease, Addison's disease, hypothyroidism, sodium depletion or conditions requiring low sodium intake. Lithium should not be given to mothers who are breast feeding a child.

Use in pregnancy: There is epidemiological evidence that the drug may be harmful in human pregnancy. Should the use of lithium be unavoidable, close monitoring of serum concentrations should be made throughout the pregnancy and during parturition.

Precautions: Pre-treatment and periodic routine clinical monitoring is essential. This should include assessment of renal function, urine analysis, assessment of thyroid function and cardiac function, especially in patients with cardiovascular disease. Patients should be euthyroid before the initiation of lithium therapy. Clear instructions regarding the symptoms of impending toxicity should be given by the doctor to all patients receiving long-term lithium therapy (see Warnings and Adverse Effects). Patients should also be warned to report if polyuria or polydypsia develop. Episodes of nausea and vomiting or other conditions leading to salt/water depletion (including severe dieting) should also be reported. Patients should be advised to maintain their usual salt and fluid intake. Elderly patients are particularly liable to lithium toxicity.

Drug interactions: Lithium should only be given with great care to patients taking diuretics. Lower doses of lithium may be needed during diuretic therapy as lithium clearance is reduced. In some cases, a paradoxical antidiuretic effect leading to water retention has been reported following the use of diuretics during treatment with lithium salts. There is a possibility of water intoxication and lithium intoxication when diuretics and lithium salts are co-prescribed.

Raised plasma levels of ADH may occur during lithium therapy. Symptoms of nephrotoxic diabetes are particularly prevalent in patients receiving concurrent treatment with tri/tetracyclic antidepressants. Serum lithium concentrations may increase during concomitant therapy with indomethacin or tetracycline.

Warnings and Adverse Effects: Long-term treatment with lithium may result in permanent changes in the kidney and impairment of renal function. High serum concentrations of lithium, including episodes of acute lithium toxicity may enhance these changes. The mini-

mum clinically effective dose of lithium should always be used. Patients should be maintained on lithium after 3-5 years only if, on assessment, benefit persists.

Renal function should be routinely monitored in patients with polyuria and polydypsia.

Side-effects are usually related to serum lithium concentrations and are infrequent at levels below 1.0 mmol.

Mild gastrointestinal effects, nausea, vertigo, muscle weakness and a dazed feeling may occur, but frequently disappear after stabilisation. Fine hand tremors, polyuria and mild thirst may persist.

Long term treatment with lithium is frequently associated with disturbances of thyroid function including goitre, hypothyroidism and thyrotoxicosis.

Mild cognitive impairment may occur during long term use.

Hypercalcaemia, hypermagnesaemia, hyperparathyroidism and an increase in antinuclear antibodies have also been reported.

Exacerbation of psoriasis may occur.

Signs of Impending Toxicity: Appearance or aggravation of gastrointestinal symptoms, muscle weakness, lack of co-ordination, drowsiness or lethargy may be early signs of intoxication. With increasing toxicity there is ataxia, giddiness, tinnitus, blurred vision, coarse tremor, muscle twitching and a large output of dilute urine. At blood levels above 2-3 mmol/l, there is increasing disorientation, seizures, coma and death.

Overdosage: Early signs of toxicity usually respond to reduction or cessation of dosage.

There is no specific antidote for lithium poisoning. Treatment comprises general supportive measures and maintenance of electrolyte balance. Elimination of lithium may be facilitated by infusion of sodium bicarbonate, acetazolamide, urea or mannitol.

Prolonged continuous peritoneal dialysis may be more effective than haemodialysis.

Pharmaceutical precautions Store in a cool dry place.

Legal category POM.

Package quantities Securitainers of 100 and 50 tablets.

Further information Phasal is a sustained release preparation designed to facilitate control of blood lithium levels within the optimum range. The smaller diurnal variation provided by the use of a sustained release tablet: (i) reduces the risk of rapid and excessive absorption of lithium and thereby improves safety; (ii) maintains the desired blood levels and so provides continuous protection against relapse; (iii) improves convenience of dosing for the patient.

Product licence number 0108/0035R.

PREDENEMA*

Presentation Ready-to-use, self-contained, single dose, disposable enema of 100 ml buffered aqueous solution containing Prednisolone Metasulphobenzoate Sodium, equivalent to Prednisolone 20 mg.

Uses Local treatment of ulcerative colitis.

Dosage and administration *Adults only:* 1 enema nightly for two to four weeks, extending the course when

a good response is being obtained. The long tube presentation facilitates self-administration.

The enema may be administered at room temperature or warmed in warm water before use.

Contra-indications, warnings, etc Administration of prednisolone via this route for this indication is seldom associated with adverse effects. It is contra-indicated in local conditions where it might mask infection or impair healing, such as peritonitis, sinusitis, fistulae, intestinal obstruction, perforation of the bowel.

Precautions: Symptoms of adrenal insufficiency have not been reported, but prolonged therapy should be carefully monitored.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroids should not be used extensively in pregnancy, (i.e. in large amounts or for prolonged periods.)

Pharmaceutical precautions Store in a cool place, protected from light.

Legal category POM.

Package quantities Long tube box of 7 enemas
Standard tube box of 10 enemas.

Further information Nil

Product licence number 0108/5018.

RUBELIX*

Presentation Red elixir with aromatic ginger odour. Each 5 ml contains:

Pholcodine PhEur	4.0 mg
Ephedrine Hydrochloride PhEur	6.0 mg

Uses As a combined antitussive and bronchodilator for the treatment of dry, non-productive cough.

Dosage and administration *Adults:* 10 ml taken orally three or four times daily. Not more frequently than four-hourly.

Children: Age 1–5 years: 2.5 ml.

Age 5–10 years: 5.0 ml.

All three times daily.

Contra-indications, warnings, etc

Contra-indicated in the presence of coronary thrombosis, hypertension and thyrotoxicosis. Caution is required in patients with organic heart disease and those receiving digitalis. It should not be administered to patients being treated with a monoamine oxidase inhibitor.

Side-effects from Rubelix are rare. However, ephedrine, especially in large doses, may cause giddiness, headache, nausea, vomiting, thirst, palpitations, difficulty in micturition, muscle weakness, anxiety. Pholcodine may cause nausea and drowsiness.

In the event of severe toxicity, stomach aspiration and lavage may be required.

Pharmaceutical precautions Can be stored at room temperature.

Legal category P.

Package quantities Bottles of 150 ml and 2 litres.

Further information Pholcodine is a cough suppressant with mild sedative actions which relieve local

irritation of the respiratory tract; its depressant effects on respiration are less than those of morphine. The combination with the bronchodilator, ephedrine, is therefore intended for the relief of dry, unproductive cough.

Product licence number 0108/5027.

SAVENTRINE* TABLETS

Presentation White sustained release tablet with grey/brown surface speckling and 'P' in hexagon embossed on one face. Each tablet contains Isoprenaline Hydrochloride BP 30 mg.

Uses Beta-adrenergic stimulant for use in chronic atrioventricular block and Stokes-Adams attacks, heart block induced at cardiac surgery, carotid sinus, syncope; bradycardia.

Dosage and administration Dosage must be tailored to the requirements of the individual patient. Treatment is best initiated under observation in hospital with facilities available for monitoring ECG and for cardiac resuscitation.

ECG should be monitored during intravenous infusion of isoprenaline (5 mg in 500 ml of 5% dextrose solution at 10–30 drops per minute) or a 20 mg sublingual tablet. Following a favourable increase in ventricular rate without appearance or increase in the ventricular ectopic beats, oral Saventrine therapy can be started.

The usual initial dosage is 1 tablet (30 mg) eight-hourly and this can be increased quite rapidly if required. Daily dosage may range from 90 mg in some patients to 840 mg in others, with frequency of administration varying from eight-hourly to two-hourly. Optimum dosage is that which satisfactorily controls the heart rate with minimum side-effects.

Tablets must be swallowed whole, they are not for sublingual administration.

Children: Monitor and proceed as for adults.

Contra-indications, warnings, etc Saventrine is contra-indicated in acute coronary disease and in patients prone to episodes of ventricular fibrillation or tachycardia secondary to their slow rate.

Side-effects may include palpitations, tremor, tachycardia, precordial pain. Sweats, facial flushing, headache and diarrhoea have also been reported. Incidence of side-effects with this presentation is less than with sublingual isoprenaline, and side-effects usually respond to dosage adjustment.

In the event of overdose, toxic effects may be diminished by a beta-adrenergic blocking drug.

Pharmaceutical precautions Store at room temperature.

Legal category POM.

Package quantities Securitainers of 30 and 250 tablets.

Further information Saventrine contains granules of Isoprenaline Hydrochloride coated with varying numbers of layers of ethylcellulose. Following ingestion there is sustained release of active ingredient over several hours unimpeded by changes of pH, digestive enzymes or intestinal motility.

Isoprenaline is a potent sympathomimetic amine acting almost exclusively via beta-adrenergic receptors, and exerts positive chronotropic and inotropic effects on the heart. An intravenous preparation of Isoprenaline

Hydrochloride (Saventrine i.v.) is also available for monitoring purposes.

Product licence number 0108/5028.

SAVENTRINE i.v.

Presentation Glass ampoules containing a stabilised solution of Isoprenaline Hydrochloride BP for injection. Each ampoule contains 2 ml of 1 mg/ml solution.

Uses Beta-adrenergic stimulant for use in:

1. Monitoring of patients with heart block to determine their suitability for treatment on a long-term basis with Saventrine sustained action oral tablets.
2. Cardiogenic or endotoxic shock states.
3. Acute Stokes-Adams attacks and other cardiac emergencies.
4. Certain other slow heart states, e.g. severe bradycardia precipitated by beta-adrenergic antagonists.
5. Evaluation of congenital heart defects.

Dosage and administration The usual route is by intravenous infusion, generally in 5% dextrose solution. Widely varying doses have been used with success.

1. Monitoring heart block: 5–40 mcg/min.
2. Shock states: 0.5–10 mcg/min.
3. Acute Stokes-Adams attack: 4–8 mcg/min or alternatively, intracardiac injection of 0.1 mg in 10 ml water.
4. Slow heart states: 1–4 mcg/min.
5. Congenital cardiac defects: 1.5–4 mcg/min.

Children: Adjust above dosage in proportion to weight.

Contra-indications, warnings, etc Isoprenaline may precipitate ventricular extrasystoles and arrhythmias, especially in patients who may be hypersensitive to the drug. In such cases the infusion rate should be reduced or possibly discontinued.

Side-effects may include palpitations, tremor, precordial pain, sweats, facial flushing, headache.

In the event of overdosage, a beta-adrenergic blocking drug may diminish toxic effects.

Pharmaceutical precautions Store in a cool place protected from light.

Legal category POM.

Package quantities Carton of 6 ampoules.

Further information Isoprenaline Hydrochloride is a sympathomimetic amine with potent activity at beta-adrenergic receptors. See also Saventrine tablets.

Product licence number 0108/5030.

SUSCARD* BUCCAL TABLETS ▼

Presentation White biconvex tablets, marked with 'P' inside a hexagon on one face; dosage strength on other face. Suscard is a sustained release presentation of glyceryl trinitrate in three strengths, 1 mg, 2 mg and 5 mg, for buccal administration (see below).

Uses The management and treatment of angina pectoris; congestive cardiac failure.

Dosage and administration The Suscard tablet is placed high up between the upper lip and the gum to either side of the front teeth.

The diagram below shows the correct placement of the tablet.

THE TABLETS SHOULD NOT BE PLACED UNDER THE TONGUE, CHEWED OR INTENTIONALLY SWALLOWED.

The onset of action of Suscard tablets is extremely rapid, and the tablets may be substituted for sublingual glyceryl trinitrate tablets in the treatment of acute angina pectoris. The duration of action of the Suscard tablet, once in place, as shown above, correlates with the dissolution time of the tablet. This is normally 3–5 hours. However, the first few doses may dissolve more rapidly until the patient is used to the presence of the tablet.

During the dissolution period the tablet will soften and adhere to the gum; in practice the presence of the tablet is not noticeable to the patient after a short time.

Angina: Administration of Suscard tablets should start with the 1 mg strength. If angina occurs while the tablet is in place, the dosage strength used should be increased to 2 mg. The 5 mg dosage strength should be reserved for patients with severe angina pectoris refractory to treatment with the lower dosage strengths.

Suggested dosage frequency in angina:

- (a) For patients suffering only occasional angina pectoris: the tablets may be administered on a p.r.n. basis, to relieve the acute attack.
- (b) For patients suffering angina pectoris in response to known stimuli: the tablet may be administered a few minutes prior to encountering the angina-precipitating stimulus.
- (c) For patients in whom chronic therapy is indicated: the tablet should be administered on a thrice daily basis or as dictated by the dissolution rate of the tablet in an individual patient. If angina occurs during the period between the disappearance of one tablet and the time the next tablet is due to be put in place, dosage frequency should be increased.

Note that if an acute attack of angina pectoris is suffered while a tablet is in place, an additional tablet may be positioned on the opposite side of the mouth.

Congestive cardiac failure: dosage should commence with the 5 mg strength, administered three times daily. In moderately severe or severe cases, particularly where patients have not responded to standard therapy (digitalis/diuretics), the dosage may need to be increased to 10 mg (2 × 5 mg tablets) t.i.d. over a period of three or

Each tablet should be placed on the gum, on each side of the

as to the correct position. The following

movement about the mouth will cause it to dissolve

as for sublingual glyceryl trinitrate a few minutes after taking

If swallowed it may be ineffective. In some cases, the tablet may be in position between the lip

the placement of successful left sides of the front

here with the ingestion of

Contra-indications, etc. Contra-indications. Sustac tablets should not be used in patients with marked anaemia, head or closed angle glaucoma, severe headache and facial severe side-effects, the from the mouth. Side-effects include vomiting, cyanosis, methaemoglobinemia and syncope. Numbers of tablets have been treated with gastric aspiration to respiratory and

Can be stored at room

2 mg: Bottles of 100

ets.

th surface speckling and one face. Sustac is a

sustained release presentation of glyceryl trinitrate in three strengths; 2.6 mg, 6.4 mg and 10.0 mg.

Uses Prophylactic therapy of angina pectoris.

Dosage and administration Sustac tablets must be swallowed whole. They are not for sublingual administration. Dosage should be tailored to the requirements of the individual patient, but is usually 1 or 2 tablets of the 2.6 mg or 6.4 mg strength taken two or three times daily, or 1 tablet of the 10 mg strength two or three times daily.

Suggested initial doses: *Mild angina:* One 2.6 mg tablet three times daily.

Moderate angina: One 6.4 mg tablet two or three times daily.

Severe angina: One or two 6.4 mg tablets three times daily, or one 10 mg tablet three times daily.

Contra-indications, warnings, etc

Contra-indications are as for glyceryl trinitrate. Sustac should not be used in patients with marked anaemia, head trauma, cerebral haemorrhage, incipient glaucoma.

Side-effects include facial flushing and headache. Toxic effects of glyceryl trinitrate include vomiting, restlessness, cyanosis, methaemoglobinemia and syncope.

Overdosage should be treated with gastric aspiration and lavage, plus attention to respiratory and circulatory defects.

Pharmaceutical precautions Can be stored at room temperature.

Legal category P.

Package quantities 2.6 mg and 6.4 mg: Securitainers of 250 tablets. 10 mg: Bottles of 100 tablets.

Further information Sustac tablets contain granules of glyceryl trinitrate coated with varying numbers of layers of ethycellulose. Following ingestion there is sustained release of active ingredient over several hours, unimpeded by changes of pH, digestive enzymes or intestinal motility.

Sustac can be used in combination with reduced beta-blockade dosage to give a patient full anti-anginal support, and at the same time reduce the likelihood of beta-blockade side-effects.

CEANEL* CONCENTRATE

Presentation *Appearance:* Ceanel Concentrate is a clear, viscous amber-coloured liquid.

Active ingredients:

Cetrimide BPC	10%
Phenylethyl Alcohol BPC	7.5%
Undecenoic Acid BP	1%

Uses *Main pharmacological action:* Cetrimide is particularly active against Gram-positive organisms. This feature combined with the bactericidal action of phenylethyl alcohol and the fungicidal properties of undecenoic acid makes Ceanel Concentrate particularly effective in the treatment of dermatological conditions. Ceanel Concentrate is effective in removing debris and scale in seborrhoea capitis, and psoriasis of the scalp.

Indications: Psoriasis of the scalp, seborrhoeic dermatitis, dandruff, psoriasis of the trunk and limbs.

Dosage and administration *Adults and children:*

Scalp conditions: Wet the scalp and hair with warm water. Protect the eyes with a towel to avoid discomfort. Apply $\frac{1}{2}$ –1 teaspoonful of Ceanel to the wetted scalp. Then apply a small amount of water and work up into a lather. Rinse and repeat. Finally rinse the hair and scalp thoroughly. Use three times in the first week and twice weekly thereafter.

Other areas of the body: Wet the area to be treated with warm water; apply sufficient Ceanel concentrate by gentle massage to cover the wetted area. Allow to remain in contact for two minutes. Remove the Ceanel by thorough rinsing with warm water. Use as required.

Contra-indications, warnings, etc *Precaution:* The eyes should be protected during treatment. A simple way to do this is with a towel.

Overdosage: Ceanel Concentrate is for external use only. If Ceanel Concentrate is accidentally taken by mouth treat as for cetrimide poisoning.

For external use only. Keep out of the reach of children.

Pharmaceutical precautions *Storage:* No special precaution required.

Diluents: Ceanel Concentrate is easily removed by warm water.

Legal category P.

Package quantities Available in packs of 50 ml and 500 ml.

Further information In clinical trials Ceanel Concentrate was used on 31 patients suffering from psoriasis, seborrhoeic eczema, atopic eczema or infected eczema of the scalp. A complete clearing of scaling was obtained in 24 of the 25 patients with psoriasis, and in all six patients with eczema.

Greasiness of the scalp was eliminated in 20 of the 21 patients with psoriasis who showed this feature.

Product licence number 0291/5002.

ECZEDERM* CREAM

Presentation *Appearance:* Eczederm is a pink-coloured cream.

Active ingredients:

Calamine BP	20.88%
Starch (Maize) BP	2.09%
Emollient Base to	100%

Uses *Pharmacological actions:* The soothing and healing properties of Calamine have been combined with the bland cooling effect from the special emollient base. This has produced a unique blend of useful therapeutic properties.

Indications: Mild dermatoses including both wet and dry eczema especially where steroid containing preparation should be avoided.

Dosage and administration *Adults and children*

Spread thinly over the affected area up to three times a day. The use of occlusive dressings may be considered in dry scaly dermatoses.

Contra-indications, warnings, etc Eczederm cream is for topical use only. There are no known contra-indications except true hypersensitivity to one of the ingredients. Ingestion should be avoided.

Pharmaceutical precautions *Storage:* Eczederm should be stored in a cool place and extremes of temperature avoided.

Diluents etc: Eczederm is not suitable for dilution or reformulation.

Legal category P.

Package quantities Eczederm is supplied in tubes of 25 g.

Further information This preparation does not contain Parabens type compounds or Lanolin. It is of special use where steroid containing preparations are contra-indicated.

Product licence number 0291/0003.

ECZEDERM* CREAM WITH HYDROCORTISONE 0.5%

Presentation *Appearance.* Eczederm Cream with Hydrocortisone 0.5% is a pink-coloured cooling cream.

Active ingredients:

Calamine BP	20.88%
Starch (Maize) BP	2.09%
Hydrocortisone BP	0.5%

Uses *Main pharmacological action:* The combination of the properties of hydrocortisone, with the mild astringent properties of calamine in a bland cooling-cream base results in a preparation which can have anti-inflammatory soothing and emollient properties.

Indications: Dry scaly eczematous dermatoses and wet exudative eczematous dermatoses.

Dosage and administration *Adults and children:* Spread thinly over the affected area up to three times daily in both forms of eczema.

Contra-indications, warnings, etc *Warning:* In pregnant animals, administration of corticosteroids can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for long periods.

In infants, long-term continuous topical therapy should be avoided. Adrenal suppression can occur even without occlusion.

This preparation is for external use only.

Keep out of the reach of children.

Pharmaceutical precautions *Storage:* Eczederm Cream with Hydrocortisone 0.5% should be stored in a cool place, avoiding extremes in temperature.

Legal category POM.

Package quantities Eczederm Cream with Hydrocortisone 0.5% is available in tubes of 25 g.

Further information This preparation does not contain any Parabens-type compounds or lanolin.

Product licence number 0291/5004.

HIOXYL* CREAM

Presentation A smooth, white, non-greasy cream with virtually no odour, containing stabilised Hydrogen Peroxide 1.5%.

Uses The antiseptic effect of Hydrogen Peroxide is a result of its ready release of oxygen when applied to tissues. The effect only lasts as long as oxygen is being released, and for solutions of Hydrogen Peroxide, this is only of short duration.

Hioxyl Cream is a unique formulation in which Hydrogen Peroxide has been stabilised in a soothing, easy to apply, cream to give prolonged antiseptic action.

Indications: The treatment of minor wounds, skin ulcers and infections.

Dosage and administration Hioxyl Cream is applied freely using a piece of lint or gauze. If necessary it may be covered with a dressing. The application can be repeated as required.

Contra-indications, warnings, etc There are no known contra-indications or warnings to the use of Hioxyl Cream.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Tubes of 25 g and 100 g.

Further information Care should be taken to avoid usage with other topical medicaments due to possible chemical interaction negating the active principle.

Product licence number 0291/0008.

QUINODERM* CREAM

Presentation *Appearance:* Quinoderm Cream is a creamy white astringent vanishing cream.

Active ingredients:

Benzoyl peroxide	10%
Potassium Hydroxyquinoline Sulphate BPC	0.5%

Uses *Main pharmacological action:* The combination of the mild keratolytic properties of benzoyl peroxide and the antibacterial, antifungal and deodorant properties of potassium hydroxyquinoline sulphate in a specially formulated bland water-miscible base makes this preparation valuable in the treatment of pustular affections of the skin, particularly when associated with staphylococcal infection.

Indications: Acne vulgaris, acne rosacea, acneform eruptions, acne varioliformis, impetigo, sycosis barbae, folliculitis.

Dosage and administration Quinoderm Cream is used topically.

Adults and children: By gentle massage over all the affected area, two or three times daily.

Contra-indications, warnings, etc *Precaution:* In a few isolated cases overreaction to Quinoderm Cream may occur. To minimise this possibility, select a small area of skin behind the ear, apply the cream and leave for 12 hours. If severe irritation or pronounced redness occurs do not proceed.

For external use only. Keep out of the reach of children.

Pharmaceutical precautions *Storage:* Quinoderm Cream should be stored in a cool place, avoiding extremes of temperature.

Diluents, etc: Quinoderm Cream can be easily removed by warm water and soap.

Legal category P.

Package quantities Quinoderm Cream is supplied in tubes of 25 g and 50 g.

Further information In clinical trials in acne vulgaris 81 patients out of 106 showed a good or very good response to Quinoderm Cream. In acne rosacea 7 out of 11 patients showed a good or very good response to this preparation.

Product licence number 0291/5000.

QUINODERM* CREAM WITH HYDROCORTISONE 1%

Presentation *Appearance:* Quinoderm Cream with Hydrocortisone 1% is a creamy white astringent vanishing cream.

Active ingredients:

Benzoyl peroxide	10%
Potassium Hydroxyquinoline Sulphate BPC	0.5%
Hydrocortisone BP	1%

Uses *Main pharmacological action:* The combination of the anti-inflammatory properties of hydrocortisone, the keratolytic action of benzoyl peroxide and the antibacterial, antifungal and deodorant properties of potassium hydroxyquinoline sulphate in an astringent cream base makes this preparation valuable in the treatment of pustular affections of the skin, particularly when associated with staphylococcal infection.

Indications: Severe acne vulgaris, acne rosacea, acneform eruptions, acne varioliformis, impetigo, sycosis barbae, folliculitis and perifolliculitis.

Dosage and administration *Adults and Children:* Spread thinly over the affected area and then gently massage until no trace of the cream can be seen on the skin surface. Apply two or three times daily. It is important that the whole of the area be treated, not just individual spots or blemishes.

Contra-indications, warnings, etc

Contra-indications: None.

Warning: In pregnant animals, administration of corticosteroids can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for long periods.

In infants, long-term continuous topical therapy should be avoided. Adrenal suppression can occur even without occlusion.

This preparation is for external use only.

Keep out of the reach of children.

Pharmaceutical precautions *Storage:* Quinoderm Cream with Hydrocortisone 1% should be stored in a cool place, avoiding extremes of temperature.

Diluents: The cream is easily removed by warm water and soap.

Legal category POM.

Package quantities Quinoderm Cream with Hydrocortisone is available in tubes of 30 g.

Further information In clinical trials in acne vulgaris 41 patients out of 46 showed a good or very good response to Quinoderm Cream with hydrocortisone 1% and in acne rosacea 21 patients out of 21 showed a good or very good response to this preparation.

Product licence number 0291/5001.

QUINODERM LOTIO-GEL*

Presentation Quinoderm Lotio-Gel contains colloidal benzoyl peroxide 10% and Potassium Hydroxyquinoline Sulphate BPC 0.5% in a homogeneous astringent gel formulated to give the colour and consistency of a creamy white lotion.

Uses Quinoderm Lotio-Gel is indicated in the treatment of acne.

The main pharmacological action of benzoyl peroxide is considered to be keratolytic and comedolytic. Potassium hydroxyquinoline sulphate has broad spectrum antibacterial activity. This combination is formulated in a specifically researched and developed base and is designed to aid the resolution of the polymorphic lesions of acne.

The base has been developed with the objective of providing a stable pharmaceutical form which maximises the advantages of a gel and lotion in a system which does not employ organic solvents and therefore has a correspondingly lower irritancy, toxicity and abuse potential.

Dosage and administration The preparation should be applied by gentle massage over all the affected area, one to three times daily.

Contra-indications, warnings, etc Patients with known sensitivity to either of the active constituents should not use Quinoderm Lotio-Gel.

In a few isolated cases overreaction to Quinoderm Lotio-Gel may occur. To minimise this possibility, select a small area of skin behind the ear, apply the Lotio-Gel and leave for 12 hours. If severe irritation or pronounced redness occurs, do not proceed.

All medicines should be kept out of the reach of children.

Contact with mouth and eyes should be avoided.

Care should be taken to avoid contact with dyed fabrics as this preparation may adversely affect dye fastness.

Pharmaceutical precautions Quinoderm Lotio-Gel should be stored in a cool place avoiding extremes of temperature.

Legal category P.

Package quantities Quinoderm Lotio-Gel is available in plastic bottles of 30 ml.

Further information Patients may vary in their response to benzoyl peroxide preparations. The stability of benzoyl peroxide in Quinoderm Lotio-Gel is enhanced to minimise any variation in response which may be attributable to variations in the concentration of this active constituent.

Product licence number 0291/0007.

QUINOPED* CREAM

Presentation *Appearance:* Quinoped Cream is a cream-coloured astringent cream.

Active ingredients:

Benzoyl peroxide 5%

Potassium Hydroxyquinoline Sulphate BPC 0.5%

Uses *Main pharmacological action:* Benzoyl peroxide functions as a keratolytic and facilitates the removal of macerated tissue and associated debris. Potassium hydroxyquinoline sulphate has antifungal and deodorant properties.

Indications: Athlete's foot (tinea pedis) and related fungal infections.

Dosage and administration *Adults and children:* Spread thinly over all the affected area and gently massage until no trace of the cream can be seen on the skin surface. Apply morning and night.

Contra-indications, warnings, etc For external use only. Keep out of the reach of children.

Pharmaceutical precautions *Storage:* Quinoped Cream should be stored in a cool place, avoiding extremes of temperature.

Diluents: The cream is easily removed with warm water and soap.

Legal category P.

Package quantities Quinoped Cream is available in tubes of 25 g.

Further information Quinoped Cream is a balanced formulation to counteract the effect of *T. rubrum*, *T. interdigitale* and *E. floccosum*.

Product licence number 0291/0002.

CODIS*

Presentation White tablets, engraved on both sides with the letter 'C' and a sword. Each tablet contains Aspirin BP 500 mg and Codeine Phosphate PhEur 8 mg and when dissolved in water provides a palatable solution of calcium acetylsalicylate and codeine phosphate.

Uses As an analgesic and antipyretic for the relief of mild to moderate pain, including headaches, migraine, neuralgia, toothache, period pains, aches and pains and the symptoms of colds, influenza and feverish conditions. The symptomatic relief of sprains, strains, rheumatic pain, sciatica, lumbago, fibrositis, muscular aches and pains, joint swelling and stiffness.

Dosage and administration

Adults: 1-2 tablets, dissolved in water; the dose may be repeated after four hours; maximum 8 tablets daily, in divided doses. Codis is not recommended for children under 12 years of age.

Contra-indications, warnings, etc The unwanted effects of Codis are those normally associated with soluble aspirin and codeine. It should not be given to patients known to be allergic to aspirin, or suffering from active peptic ulceration or haemophilia.

There is clinical and epidemiological evidence for the safety of aspirin in human pregnancy, but it may prolong labour and contribute to maternal and neonatal bleeding, and is therefore best avoided at term. Aspirin may precipitate bronchospasm, and induce attacks of asthma in susceptible subjects; it may also induce gastro-intestinal haemorrhage, occasionally major. Aspirin may enhance the effects of anticoagulants and inhibit the effects of uricosurics.

For *overdosage*, water or milk, given immediately, may delay absorption. The usual procedures for aspirin overdosage should be followed, including general supportive measures and gastric lavage if necessary. For respiratory depression caused by the codeine, nalorphine or naloxone should be given by injection. It is advisable for the patient to be sent to hospital for appropriate biochemical assessment and treatment.

Pharmaceutical precautions Keep in a cool, dry place.

Legal category P.

Package quantities Cartons of 8, 20, 48 and 500 tablets in foil.

Further information Because the aspirin and codeine phosphate are taken in solution, effective blood levels and relief of pain may be achieved more rapidly than with ordinary aspirin or codeine tablets. The superiority of soluble aspirin over ordinary aspirin in the rapid achievement of demonstrable blood levels has been confirmed by several clinicians.

Product licence number 0044/5003R.

Product licence held by Reckitt & Colman Pharmaceutical Division.

FLENAC*

Presentation White, biconvex tablets each containing 300 mg fenclofenac, engraved on one side with 'Flenac' and on the other with a sword.

Uses For the treatment of chronic and sub-acute rheumatological conditions, such as rheumatoid arthritis, ankylosing spondylitis and osteoarthritis.

Dosage and administration The dose range is up to 1,200 mg (4 tablets) daily, on a twice-daily (night and morning) regimen, taken with or after food.

A maintenance dose of 900 mg (3 tablets) daily is suitable for most adult patients, with two tablets at night and one in the morning to combat early morning stiffness, as in rheumatoid arthritis, or alternatively one tablet at night and two in the morning for daytime pain and stiffness, as in osteoarthritis.

An initial regimen based on these criteria can be adjusted to between 600 mg and 1,200 mg daily according to the response and needs of the patient.

Flenac is not at present recommended for children.

Contra-indications, warnings, etc Flenac is contra-indicated if the patient is known to be suffering from active peptic ulceration or gastric bleeding.

Warnings: Flenac should not be prescribed for children or for pregnant or lactating women, until paediatric indications and dosage have been established, and its safety in pregnancy demonstrated.

Due to the high plasma protein binding of Flenac, patients simultaneously receiving hydatants, anticoagulants or the sulphonamide hypoglycaemic drugs, should be observed for signs of possible interaction.

Care should be taken when treating patients with known renal or hepatic dysfunction, eczema, asthma or known sensitivity to aspirin or other non-steroidal anti-inflammatory drugs. As with other drugs of this type, small increases in blood urea levels have been observed.

Side-effects: Cases of gastro-intestinal discomfort, including nausea, have been reported, but were infrequent and generally mild, and usually responded to a reduction of dosage; symptoms severe or persistent enough to require withdrawal were rare.

Rashes are the most frequently encountered adverse reaction. They are usually relatively mild and regress when treatment is stopped. Erythema multiforme has been reported and also, though more rarely, the Stevens-Johnson Syndrome and toxic epidermal necrolysis. In some patients with a mild rash, therapy has been reintroduced without any recurrence.

Overdosage: No case of overdosage has been reported. There is no specific antidote to fenclofenac, but in the

event of overdosage standard procedures such as gastric lavage and supportive treatment should be used, and the patient kept under strict observation.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Blister packs of 10 tablets, in boxes of 100 tablets.

Further information The long duration of action of Flenac indicates that twice daily dosage is usually sufficient. Flenac is well tolerated by most patients, even over a long period, and offers effective relief of the pain, inflammation and early-morning stiffness associated with rheumatological conditions.

In patients with rheumatoid arthritis, treatment with Flenac has been associated with highly significant falls in E.S.R. over prolonged periods.

Flenac has also been shown to be an effective prostaglandin synthetase inhibitor, with a potency approximately eight times greater than that of aspirin.

Animal and human studies indicate a lower level of gastro-intestinal toxicity than that of most anti-inflammatory agents. However, caution should clearly be exercised when it is proposed to administer Flenac to patients with a history of ulceration of other gastro-intestinal disturbance.

Total levels of thyroid hormones are reduced below normal in patients on Flenac therapy due to a plasma protein binding interaction and this effect makes interpretation of thyroid function tests difficult. If assessment of thyroid function is required during Flenac therapy, then TSH and/or free T_3 and T_4 levels should be measured since these should be within the normal ranges. Fenclofenac interferes with competitive binding assays for thyroid hormones, which use thyroxine binding globulin as the binding protein, and therefore radio-immunoassay methods are recommended.

Product licence number 0044/0060.

Product licence held by Reckitt & Colman Pharmaceutical Division.

FYBOGEL® FYBOGEL® ORANGE

Presentation *Fybogel*: Flaky granules of a pale buff colour.

Fybogel Orange: Flaky granules of a pale orange colour with an orange flavouring.

One sachet of granules contains Ispaghula Husk BPC 3.5 g.

Uses Fybogel is recommended for the treatment of patients requiring a high-fibre regimen.

Dosage and administration *Adults: children over 12*: One sachet morning and evening.

Children under 12: $\frac{1}{2}$ –1 level 5 ml spoonful depending on age and size morning and evening.

Fybogel should be stirred into water and taken as soon as possible, preferably after meals.

Contra-indications, warnings, etc Fybogel is contra-indicated in cases of intestinal obstruction and colonic atony such as senile megacolon.

In the event of overdosage conservative measures should be taken. The patient may notice abdominal discomfort and flatulence, and attention should be paid

to maintaining an adequate fluid intake particularly if the granules have been taken without water contrary to the administration instructions.

Pharmaceutical precautions Nil.

Legal category GSL.

Package quantities Carton of 10 sachets.

Further information Daily Fybogel therapy provides a high-fibre regimen. Ispaghula husk; is capable of retaining 40 times its weight of water, promoting easy evacuation and avoiding episodes of straining. Fybogel effervescent granules disperse readily to form a palatable drink in water. The unflavoured form of Fybogel may be mixed with fruit squash to vary the flavour. Each sachet of Fybogel contains 6.0 mmol sodium. Each sachet of Fybogel Orange contains 6.1 mmol sodium.

Fybogel 0044/0041

Fybogel Orange 0044/0068.

Product licence held by Reckitt & Colman Pharmaceutical Division.

LIQUID GAVISCON®

Presentation A pink suspension with a flavour of fennel (similar to aniseed).

10 ml of Liquid Gaviscon contains Sodium Alginate BPC 500 mg, Sodium Bicarbonate PhEur 267 mg in an inert base including Saccharin BP.

Uses Gaviscon alleviates the painful conditions resulting from the reflux of gastric acid and bile into the oesophagus, by suppressing the reflux itself. It is indicated in heartburn, including heartburn of pregnancy, dyspepsia associated with gastric reflux, hiatus hernia, reflux oesophagitis, regurgitation and all cases of epigastric and retrosternal distress where the underlying cause is gastric reflux.

Dosage and administration *Adults, children over 12*: 10–20 ml (dosage measure provided) after meals and at bedtime.

Children under 12: 5–10 ml after meals and at bedtime. Infants not recommended. See Infant Gaviscon. If desired, the standard dose of Liquid Gaviscon may be taken diluted with not more than an equal quantity of water, well stirred.

Contra-indications, warnings, etc There are no specific contra-indications, and no unwanted effects have been reported.

As Gaviscon's mode of action is almost entirely physical, overdosage presents virtually no hazard, and no ill-effects have been reported. The only likely consequence is abdominal distension, which is best treated conservatively.

Pharmaceutical precautions Store in a cool place.

Legal category GSL.

Package quantities Amber bottles of 500 ml.

Further information On ingestion Gaviscon reacts with gastric acid to produce in the stomach a floating viscous gel of higher pH than normal gastric contents, this effectively impedes reflux. In severe cases the gel itself may be refluxed into the oesophagus, where it protects the inflamed mucosa, thus allowing healing to take place and preventing further inflammation.

The sodium content of a dose of 10 ml liquid is 145 mg (6.3 mmol) this may be of importance when a highly restricted salt diet is required as in some renal and cardiovascular conditions.

Product licence number 0044/0058.

Product licence held by Reckitt & Colman Pharmaceutical Division.

GAVISCON® TABLETS

Presentation White, mint-flavoured tablet engraved on both sides with the word 'Gaviscon' and a sword symbol. Each tablet contains Alginate Acid BPC 500 mg, Magnesium Trisilicate BP 25 mg, Dried Aluminium Hydroxide Gel BP 100 mg, Sodium Bicarbonate PhEur 170 mg in an inert base including: Sucrose PhEur and Mannitol BP.

Uses Gaviscon alleviates the painful conditions resulting from the reflux of gastric acid and bile into the oesophagus by suppressing the reflux itself. It is indicated in heartburn, including heartburn of pregnancy, dyspepsia associated with gastric reflux, hiatus hernia, reflux oesophagitis, regurgitation and all cases of epigastric and retrosternal distress where the underlying cause is gastric reflux.

Dosage and administration *Adults, children over 12:* 1 or 2 tablets after meals and at bedtime.

Children under 12: 1 tablet after meals and at bedtime. Infants not recommended. See Infant Gaviscon.

Tablets should be thoroughly chewed (they can be broken and chewed a little at a time) and may be followed by a drink of water.

Contra-indications, warnings, etc There are no specific contra-indications, and no unwanted effects have been reported.

As Gaviscon's mode of action is almost entirely physical, overdosage presents virtually no hazard, and no ill-effects have been reported. The only likely consequence is abdominal distention which is best treated conservatively.

Pharmaceutical precautions Nil.

Legal category GSL.

Package quantities Carton containing 3 tubes of 20 tablets.

Further information On ingestion, Gaviscon reacts with gastric acid to produce in the stomach a floating viscous gel of higher pH than normal gastric contents; this effectively impedes reflux. In severe cases the gel itself may be refluxed into the oesophagus, where it protects the inflamed mucosa, thus allowing healing to take place and preventing further inflammation.

Care should be taken when treating diabetic patients, owing to the sugar content of the tablets. The sodium content of a tablet is 46.5 mg (2.05 mmol).

Product licence number 0044/0021.

Product licence held by Reckitt & Colman Pharmaceutical Division.

GAVISCON® GRANULES

Presentation Brown, chocolate-flavoured granules. One sachet of granules contains Alginate Acid BPC 481 mg, Sodium Alginate BPC 521 mg, Magnesium

Trisilicate BP 52 mg, Dried Aluminium Hydroxide Gel BP 208 mg, Sodium Bicarbonate PhEur 177 mg in an inert base including Sucrose PhEur.

Uses Gaviscon alleviates the painful conditions resulting from the reflux of gastric acid and bile into the oesophagus by suppressing the reflux itself. It is indicated in heartburn, including heartburn of pregnancy, dyspepsia associated with gastric reflux, hiatus hernia, reflux oesophagitis, regurgitation, and all cases of epigastric and retrosternal distress where the underlying cause is gastric reflux.

Dosage and administration *Adults, children over 12:* 1 sachet after meals and at bedtime.

Children under 12: $\frac{1}{2}$ sachet (1 level 5 ml spoonful granules) after meals and at bedtime. Infants: Not recommended. See Infant Gaviscon.

Granules should be thoroughly chewed and may be followed by a drink of water.

Contra-indications, warnings, etc There are no specific contra-indications and no unwanted effects have been reported. As Gaviscon's mode of action is almost entirely physical, overdosage presents virtually no hazard, and no ill-effects have been reported. The only likely consequence is abdominal distention which is best treated conservatively.

Pharmaceutical precautions Nil.

Legal category GSL.

Package quantities Cartons of 10 sachets.

Further information On ingestion, Gaviscon reacts with gastric acid to produce in the stomach a floating viscous gel of higher pH than normal gastric contents; this effectively impedes reflux. In severe cases the gel itself may be refluxed into the oesophagus, where it protects the inflamed mucosa, thus allowing healing to take place and preventing further inflammation.

Care should be taken when treating diabetic patients owing to the sugar content of the granules. The sodium content of a sachet is 122 mg (5.3 mmol).

Product licence number 0044/5008.

Product licence held by Reckitt & Colman Pharmaceutical Division.

INFANT GAVISCON®

Presentation Infant Gaviscon is a fine white powder, packed in a sachet and sterilised. Each sachet contains Alginate Acid BPC 924 mg, Magnesium Trisilicate BP 50 mg, Dried Aluminium Hydroxide Gel BP 200 mg and Sodium Bicarbonate PhEur 340 mg, in a base containing colloidal silica (Aerosil) and Mannitol BP.

Uses Infant Gaviscon helps to prevent gastric regurgitation in infants, where competence of the cardiac sphincter has not been fully established.

Its indications are gastric regurgitation, gastro-oesophageal reflux and reflux associated with hiatus hernia in infants and young children.

Dosage and administration *Young children:* The contents of 1 sachet mixed with half a tumbler of water after each meal. Infants: $\frac{1}{2}$ –1 sachet mixed with the made-up feed immediately before use. Any unused powder should be discarded.

Contra-indications, warnings, etc Not to be used in premature infants, or in situations where excessive water-loss is likely, e.g. fever or high room-temperature. Care should be taken when treating infants with gastroenteritis or known or suspected renal disease or impairment, as the sodium content (93 mg, or 4 mmol per sachet) may add to the risk of hyponatraemia.

As Infant Gaviscon's mode of action is almost entirely physical there are virtually no systemic unwanted effects resulting from overdosage. Overdosage may lead to gastric distension, which is best treated conservatively. Gross overdosage has been reported as causing an intragastric mass.

Pharmaceutical precautions Nil.

Legal category GSL.

Package quantities Carton of 10 sachets.

Further information Infant Gaviscon thickens a water or milk feed, and in the stomach reacts with acid gastric contents to form a viscous gel which suppresses gastro-oesophageal reflux.

Product licence number 0044/5007.

Product licence held by Reckitt & Colman Pharmaceutical Division.

PERCUTOL* ▼

Presentation A cream-coloured ointment containing glyceryl trinitrate 2% w/w in a lanolin-petrolatum base.

Uses Prophylaxis of angina pectoris.

Dosage and administration Magnitude and duration of effect is directly related to the amount of ointment applied, consequently the dosage should be titrated against the clinical presentation of the patient. One inch of ointment contains 16.64 mg glyceryl trinitrate. The ointment may be applied every 3-4 hours or less frequently as required (see further information). The usual dose is 1 to 2 inches, as squeezed from the tube, although some patients may require more. The optimum dosage is best determined by starting with an application of $\frac{1}{2}$ " ointment on the first day and increasing the dose by $\frac{1}{2}$ " increments on each successive day, until headache occurs; then reducing this length by $\frac{1}{2}$ ".

Measurement and application of Percutol is easily accomplished with the aid of the specially designed Applirule sheets supplied with the ointment. The ointment is squeezed from the tube along the graduated line on the Applirule. Using the Applirule sheet, apply the ointment, without rubbing, to any convenient part of the body preferably chest, thigh or arm and press firmly with the palm of the hand onto the skin, so as to thinly spread the ointment to cover the area beneath the Applirule.

The Applirule is then secured in place over the ointment with dressing tape or a suitable dressing.

Contra-indications, warnings, etc

Contra-indications: May be contra-indicated in patients with marked anaemia. Should not be employed in patients with known idiosyncrasies to nitrates.

Side effects: A hypotensive headache is a sign of overdosage. Occasionally elderly patients may have no untoward symptoms while recumbent but may develop postural hypotension with faintness upon suddenly rising.

Pharmaceutical precautions Keep the tube tightly closed and store in a cool place.

Legal category P.

Package quantities Tubes of 30 g.

Further information When the ointment is spread on the skin, the active ingredient (GTN) is continuously absorbed through the skin into the circulation, thus exerting a prolonged vasodilator effect.

Recent work shows a highly significant increase in exercise duration at both 5 and 8 hours after application of 2% glyceryl trinitrate ointment.¹

A controlled study to determine the best sites for application showed the chest to be the most appropriate.²

As with other vasodilators chronic therapy should not be discontinued abruptly. the frequency of application and the dosage should gradually be reduced (over a period of 4-6 weeks).

Product licence number 0044/0067.

Product licence held by Reckitt & Colman Pharmaceutical Division.

PRIPSEN*

Presentation Pripsen is a cream-coloured powder presented in a dual sachet pack. The powder forms a fine red suspension in milk or water.

Each individual sachet contains 4 g Piperazine Phosphate BP and standardised senna equivalent to 15.3 mg total sennosides calculated as sennoside B.

Uses Pripsen is a potent anthelmintic recommended for the eradication of threadworm and roundworm.

Dosage and administration

Adults and children over 6: 1 sachet. Repeat after 14 days.

Children aged 1-6 years: $\frac{2}{3}$ sachet (2 level 5 ml spoonsful). Repeat after 14 days.

Infants - 3 months to 1 year: $\frac{1}{3}$ sachet (1 level 5 ml spoonful). Repeat after 14 days.

Pripsen should be stirred into a small glass of milk or water and drunk immediately.

When treating roundworms, additional single prophylactic doses at monthly intervals may be necessary to eliminate the risk of reinfection.

Contra-indications, warnings, etc Pripsen should not be used in patients with severe bilateral renal dysfunction.

As doses are normally separated by at least 14 days the rare neurotoxic side-effects of piperazine (transient visual disturbance and vertigo), which are due to cumulative blood-levels, are unlikely to occur and have not been reported.

Although Pripsen has not been associated with any reports of teratogenicity, in common with most drugs, its use in the first trimester of pregnancy is not advised.

Overdose: Effects of overdosage will most likely be due to the piperazine content. Treatment by gastric lavage and supportive measures is indicated.

1. Davidov M.E. Cutaneous administration of nitroglycerin in patients with angina pectoris. *Angiology* 32(1) 16-20. 1981.
2. Hansen M.S. Application site for nitroglycerin ointment. *Am. J. Cardiol.* 42 1061. 1978.

Pharmaceutical precautions Any unused powder should be discarded.

Legal category P.

Package quantities Carton of 12 dual-sachets.

Further information Pripsen has an effective cure rate of virtually 100%, the piperazine paralysing the worms which are then evacuated before recovery by the efficient laxative action of standardised senna. Threadworms may be still in the larval stage when Pripsen is first administered so the follow-up dose should be taken after 14 days to eliminate this reinfestation.

Pripsen is ideal for mass administration where cross-infestation is likely.

Product licence number 0063/5004.

Product licence held by Westminster Laboratories Ltd.

SENOKOT*

Presentation *Tablets*: Small brown tablets engraved on one side only with the word Senokot and a sword symbol. One tablet contains standardised senna equivalent to 7.5 mg total sennosides calculated as sennoside B.

Granules: Brown chocolate-flavoured granules. One 5 ml level spoonful (2.73 g) contains standardised senna equivalent to 15 mg total sennosides calculated as sennoside B.

Syrup: Brown, fruit-flavoured syrup. One 5 ml spoonful contains standardised senna extract equivalent to 7.5 mg total sennosides calculated as sennoside B.

Uses In the management of constipation, including: Simple constipation, whether self-induced or environmental, e.g. neglect of the call to stool or poor sanitary conditions.

Constipation in old age, especially where maintenance treatment is required.

Constipation in pregnancy and the puerperium.

Idiopathic slow-transit constipation.

Constipation in the irritable bowel syndrome.

Conservative treatment of haemorrhoids.

Avoidance of straining after surgery and in cerebral and cardiovascular disease.

Dosage and administration The correct dose of Senokot is the smallest required to produce a comfortable soft-formed motion. It varies between individuals, but is generally found within the following ranges:

Adults: 2 to 4 tablets, or 1 to 2 level 5 ml spoonfuls of granules or 2 to 4 × 5 ml spoonfuls of syrup.

Children over 6 years: Half the adult dosages.

Children 2–6 years: Senokot syrup $\frac{1}{2}$ to one 5 ml spoonful for preference.

New users should start with the lowest doses and, if necessary increase it by half the initial dose each day until a comfortable formed motion is produced. If no bowel action has occurred after three days' progressively increased dosage a further medical examination should be considered.

Senokot is best taken as a single dose, at bedtime by adults and in the morning by children. The tablets can be taken with a drink, the granules can be stirred into hot milk, sprinkled on food, or eaten as they are.

Contra-indications, warnings, etc Senokot like all laxatives, should not be given when any undiagnosed

acute or persistent abdominal symptoms are present. Temporary mild griping may occur during adjustment of dosage. In case of gross accidental overdosage, where diarrhoea is severe, conservative measures are usually sufficient: generous amounts of fluid especially fruit drinks should be given.

Pharmaceutical precautions The tablets and granules should be kept in closed airtight containers, and the syrup in amber bottles as supplied. Store in a cool place.

Legal category P.

Package quantities *Tablets*: Foils of 24, tins of 50, 100, 200, 1,000.

Granules: Tins of 100 and 500 g.

Syrup: Bottles of 100 and 500 ml.

Further information The physiological action of the natural anthrone glycosides in Senokot is virtually colon-specific. The active glycosides are protected by a natural sugar moiety which safeguards their transport to the large bowel, where bacterial action breaks the sugar-anthrone bond and releases the active fraction. Peristalsis is then stimulated via the submucosal and myenteric nerve plexuses.

Being colon-specific, Senokot does not affect the vital nutritional functions of the upper gastro-intestinal tract.

Diabetic patients should use the tablets as these have a low sugar content.

Clinical studies have shown that breast fed infants of mothers taking Senokot did not show any side effects to the drug.

Granules 0063/5002

Syrup 0063/5003

Product licences held by Westminster Laboratories Ltd.

SOLPRIN*

Presentation White tablets engraved on both sides with a sword symbol. Each tablet contains Aspirin BP 300 mg, and when dissolved in water provides a palatable solution of calcium acetylsalicylate.

Uses As an analgesic, antipyretic and anti-inflammatory, for the relief of pain in headache, toothache, neuralgia, sciatica and period pains, and the reduction of inflammation in rheumatism and associated conditions.

Dosage and administration *Adults*: 1–3 tablets dissolved in water. The dose may be repeated after four hours; maximum 12 tablets daily in divided doses (in acute rheumatic conditions up to 24 tablets daily in divided doses).

Children 6–12 years: 1 tablet dissolved in water, repeated after four hours if necessary; maximum 80 mg/kg body weight daily in divided doses.

Contra-indications, warnings, etc Unwanted effects are those of soluble aspirin. Solprin should not be given to patients suffering from active peptic ulceration or haemophilia or known to be allergic to aspirin.

There is clinical and epidemiological evidence of the safety of aspirin in pregnancy, but it may prolong labour and contribute to maternal and neonatal bleeding and is best avoided at term.

Aspirin may precipitate bronchospasm, and induce attacks of asthma in susceptible subjects; it may also

induce gastro-intestinal haemorrhage, occasionally major.

Aspirin may enhance the effects of anticoagulants and inhibit the action of uricosurics.

For overdosage, the usual procedures for aspirin overdosage should be followed, including general supportive measures and gastric lavage if necessary.

Pharmaceutical precautions Nil.

Legal category GSL.

Package quantities 500 tablets in foil.

Further information Solprin is aspirin in a soluble form. Because the aspirin is taken in solution, effective blood levels and the relief of pain and inflammation may be achieved more rapidly than with ordinary aspirin; further, it is less likely to cause gastric upsets.

Product licence number 0044/5000.

Product licence held by Reckitt & Colman Pharmaceutical Division.

TEMGESIC* INJECTION

Presentation Temgesic Injection is a colourless liquid containing 0.3 mg/ml buprenorphine, as the hydrochloride, in a 5% dextrose solution, adjusted to pH range 3.5–5.5. Clear glass snap-ampoules of 1 ml (0.3 mg) or 2 ml (0.6 mg).

Uses As a strong analgesic for the relief of moderate or severe pain.

Dosage and administration *Adults:* The recommended dosage is 1 to 2 ml (0.3–0.6 mg buprenorphine), by i.m. or slow i.v. injection, every six to eight hours or as required. Temgesic is not at present recommended for children.

Contra-indications, warnings, etc There are no absolute contra-indications; however, care should be taken when treating patients with impaired respiratory function as Temgesic may rarely affect respiration. Because buprenorphine has antagonist properties, it may precipitate mild withdrawal symptoms in narcotic addicts. Temgesic may cause some drowsiness; this could be potentiated by other centrally-acting agents, including alcohol. Ambulant patients should be warned not to drive or operate machinery if affected.

Since buprenorphine is metabolised in the liver, the intensity and duration of its action may be affected in patients with impaired liver function.

Until further information is available, Temgesic should be used with caution in patients receiving monoamine oxidase inhibitors, and is not recommended for use during pregnancy.

Overdosage: Temgesic has a wide safety margin, and in clinical practice doses well in excess of those recommended have been used without untoward effect. Should respiratory depression occur to a clinically undesirable degree, supportive measures should be used to maintain adequate ventilation and oxygenation. The effects of buprenorphine are not readily reversible by such narcotic reversing agents as levallorphan, though naloxone may be partially effective; in the unlikely event of a profound respiratory depression occurring, doxapram may be used to stimulate respiration. In post-

operative patients, a component of respiratory depression may be the residual effect of previously administered narcotics, and naloxone should be given in the first instance, before the use of doxapram is considered.

Side-effects: Drowsiness, or sleep from which the patient can easily be aroused, may occur particularly in the post-operative period. Improved mood or mild euphoria have occasionally been observed and respiratory depression has been observed rarely. In common with other strong analgesics, nausea, vomiting, dizziness and sweating have been reported which may be more frequent in ambulant patients. Constipation attributable to Temgesic has not been reported.

Pharmaceutical precautions Temgesic Injection, though stable, should be kept cool and protected from light.

Legal category POM.

Package quantities Pack of 10 ampoules (1 ml or 2 ml).

Further information Temgesic Injection contains 50 mg dextrose per ml, but no sodium, potassium, or preservative).

Dependence Liability: The human and animal studies conducted indicate that buprenorphine has a substantially lower dependence profile than conventional centrally-acting analgesics.

Product licence numbers

Temgesic Injection 1 ml 0044/0056

Temgesic Injection 2 ml 0044/0057

Product licence held by Reckitt & Colman Pharmaceutical Division.

TEMGESIC* SUBLINGUAL ▼

Presentation Temgesic Sublingual tablet is a white, biconvex tablet engraved on one side with a sword-symbol, containing 0.2 mg buprenorphine, as the hydrochloride.

Uses As a strong analgesic for the relief of moderate to severe pain.

Dosage and administration 1–2 tablets (0.2–0.4 mg buprenorphine) to be dissolved under the tongue, every 6 to 8 hours or as required.

The recommended starting dose for moderate to severe pain of the type typically presenting in general practice is one tablet eight hourly.

The tablet should not be chewed or swallowed. Temgesic Sublingual is not at present recommended for children.

Contra-indications, warnings, etc There are no absolute contra-indications for Temgesic Sublingual; however, care should be taken when treating patients with impaired respiratory function as Temgesic may rarely affect respiration.

Because buprenorphine has antagonist properties, it may precipitate mild withdrawal symptoms in narcotic addicts.

Temgesic may cause some drowsiness; this could be potentiated by other centrally-acting agents, including alcohol. Ambulant patients should be warned not to drive or operate machinery if affected.

Since buprenorphine is metabolised in the liver, the intensity and duration of its action may be affected in patients with impaired liver function.

Until further information is available. Temgesic should be used with caution in patients receiving monoamine oxidase inhibitors, and is not recommended for use during pregnancy.

Overdosage: Overdosage by the sublingual route is unlikely. The expected symptoms would be drowsiness, nausea and vomiting. If tablets are swallowed, overdosage is less likely because the absorbed active ingredient is rapidly metabolised by the liver. Gastric lavage should be carried out and supportive measures instituted. The effects of buprenorphine are not readily reversible by such narcotic reversing agents as levallorphan, though naloxone may be partially effective; in the unlikely event of a profound respiratory depression occurring doxapram may be used to stimulate respiration.

Side-effects: No serious toxic reactions have been observed where Temgesic Sublingual has been given in normal therapeutic doses and side-effects are generally of a minor nature.

In common with other strong analgesics, nausea, vomiting, dizziness, sweating and drowsiness have been reported and may be more frequent in ambulant patients. Clinically significant respiratory depression has been observed rarely, and only in the post-operative period.

The psychotomimetic effects sometimes observed with other antagonist-analgesics have not been encountered with Temgesic Sublingual.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Carton of 50 tablets, blister-packs of 10 tablets each.

Further information Temgesic Sublingual has been formulated to allow the active ingredient to be absorbed through the buccal mucosa within minutes.

The tablets must not be chewed or swallowed as this will reduce the efficacy.

Dependence liability: No manifestations of physical dependence have been produced when Temgesic Sublingual has been withdrawn from patients receiving large doses of Temgesic Sublingual over long periods.

Product licence number

Temgesic Sublingual 0044/0063.

Product licence held by Reckitt & Colman Pharmaceutical Division.

TIMODINE*

Presentation Pale yellow cream containing (w/w):

Nystatin BP	100,000	i.u./g
Hydrocortisone PhEur	0.5%	
Benzalkonium Chloride Solution BP	0.2%	
Dimethicone 350 BPC	10.0%	

Uses For the treatment of dermatoses, including intertrigo, eczema, seborrhoeic dermatitis, "housewife's eczema" and pruritus ani and vulvae, in which *Candida albicans* is a factor. For the treatment of severe napkin rash involving *Candida albicans*.

Dosage and administration

Dermatoses: Sufficient Timodine should be applied to cover the lesion in a thin layer. It should then be massaged into the skin until the cream disappears. The treatment should be repeated three times a day until the lesion has healed.

Napkin Rash: After removal of the soiled napkin, the affected area should be cleaned and dried and a thin layer of Timodine applied. The treatment should be repeated after every napkin change until the lesion has healed.

Contra-indications, warnings, etc

Contra-indications: Sensitivity to benzalkonium chloride or nystatin.

Precaution: Keep away from the eyes.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

Side-effects: None have been reported.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Tubes of 30 g.

Further information Timodine is particularly indicated in the treatment of dermatoses occurring in sites, such as the skin folds, in which the special environmental conditions present predispose to maceration and chafing, leading to secondary infection with *Candida albicans* and bacteria, and causing additional inflammation and persistent pruritus.

Product licence number 1839/0001.

Product licence held by Lloyd-Hamol Ltd.

TRANSVASIN*

Presentation Creamy-white, water-miscible cream containing (w/w):

Ethyl nicotinate	2.0%
Hexyl nicotinate	2.0%
Tetrahydrofurfuryl salicylate	14.0%
Benzocaine PhEur	2.0%

Uses For the relief of rheumatic and muscular pain and the treatment of sprains and strains.

Dosage and administration *Directions for use:* Massage gently into the affected area until the cream is entirely absorbed.

Transvasin should be applied at least twice daily until the pain abates.

Contra-indications, warnings, etc

Contra-indications: Sensitivity to salicylates, nicotines or benzocaine.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Tubes of 30 g.

Further information Transvasin is a rubefacient, and within a few minutes of application a sensation of warmth is felt, followed by a reddening of the skin. This erythema does not indicate intolerance.

Product licence number 1839/5001.

Product licence held by Lloyd-Hamol Ltd.

Leics LE11 1EP

ALU-CAP*

Presentation Opaque green/red hard gelatin capsule, size 0, marked 'RIKER'. Each capsule contains 475 mg Dried Aluminium Hydroxide Gel BP as a white powder.

Uses Alu-Cap is recommended for use as a phosphate-binding agent in the management of renal failure. It may also be used as an antacid.

In the gut, aluminium hydroxide adsorbs phosphate ions. This reduces absorption of phosphate into the body, and thereby reduces serum phosphate levels. In patients with renal failure, the problem of high serum phosphate levels may be partially solved by a diet low in phosphorus. However, a more liberal diet is feasible when a phosphate-binding agent, such as aluminium hydroxide, is used.

Aluminium hydroxide gel is a slow-acting antacid. It is used to provide symptomatic relief in gastric hyperacidity. In addition, the antipeptic and demulcent activity of aluminium hydroxide helps to protect inflamed gastric mucosa against further irritation by gastric secretions.

Dosage and administration *For phosphate-binding:*

Adults and children: The dosage must be selected in accordance with individual patient requirements, and may range from 4 to 20 capsules of Alu-Cap daily (approximately 2–10 g dried aluminium hydroxide gel), taken with meals.

As an antacid: **Adults:** One Alu-Cap four times daily and on retiring. Alu-Cap is not suitable for antacid therapy in children.

Contra-indications, warnings, etc

Side-effects: Aluminium hydroxide is astringent and may cause constipation.

Precautions: Serum phosphate levels should be monitored in all patients receiving phosphate binders, to prevent the development of a phosphate depletion syndrome.

Aluminium hydroxide may form complexes with certain antibiotics (tetracyclines); concomitant administration may result in reduced absorption of the antibiotic.

Contra-indications: Patients with hypophosphataemia.

Overdosage: Symptoms and treatment: A single massive dose of aluminium hydroxide is unlikely to have harmful sequelae, as aluminium is not absorbed systemically to any great extent. Gastric lavage should be administered, followed by a mild aperient if required.

Pharmaceutical precautions No special storage precautions are required.

Legal category P.

Package quantities Bottles of 100 capsules.

Further information Nil.

Product licence number 0068/0052.

CALCISORB*

Presentation Creamy-white to beige fibrous powder. The active ingredient is the sodium salt of the phosphate ester of cellulose. Each dose of 5 g is supplied in sachet form and contains approximately 4.7 g of the active ingredient and 0.3 g of moisture.

Uses Sodium cellulose phosphate is an ion-exchange compound with a particular affinity for divalent cations. The product binds calcium ions in the lumen of the stomach and intestine and thus prevents hyperabsorption of dietary calcium. Calcium bound by cellulose phosphate is no longer available for absorption and is therefore excreted in the faeces.

Each 5 g dose will bind approximately 250 mg of calcium.

Calcisorb is used to diminish calcium absorption from the diet: 1) in the treatment of hypercalciuria and recurrent formation of renal stones; 2) in osteopetrosis; 3) as a basis of a test for calcium absorption.

Other possible uses are: 1) treatment of idiopathic hypercalcaemia of infancy; 2) treatment of hypercalcaemic sarcoidosis; 3) treatment of vitamin D intoxication.

Dosage and administration

Adults: 15 g daily, divided as three 5 g doses with meals.

Children: 10 g daily, divided as three doses with meals.

The required dose should be dispersed in water and taken orally. Alternatively the powder may be sprinkled onto food.

Contra-indications, warnings, etc Renal failure. Congestive heart failure and other conditions in which a low sodium intake is essential.

Side-effects are rare. Isolated cases of diarrhoea have been reported. One patient with mild renal disease developed a moderate magnesium deficiency. This was readily corrected by halving the dose.

No signs of calcium deficiency have been reported during the continuous use of cellulose phosphate for up to 11 years. This theoretical hazard is particularly relevant to pregnancy, but in view of the absence of data on the effect of cellulose phosphate on calcium levels in pregnant women it is recommended that treatment is discontinued during pregnancy and lactation. Likewise growing children should be prescribed Calcisorb only at the discretion of a senior physician and under his direct supervision.

Pharmaceutical precautions Since cellulose phosphate is an ester, some hydrolysis occurs on storage, the rate increasing with temperature. Calcisorb should therefore be kept in a refrigerator for long-term storage.

For short-term storage by the patient, i.e. of the order of one month, refrigeration is unnecessary. The product is supplied with a minimum expiry date of two years from manufacture.

Legal category P.

Package quantities Supplied in packs of 100 sachets.

Further information Calcisorb should be used in conjunction with a low calcium diet in which dairy products in particular are severely restricted.

Product licence number 0068/5900

DISALCID*

Presentation Grey and orange hard gelatin capsule, size 0, marked DS on one half and RIKER on the other.

Each 'Disalcid' capsule contains salsalate 500 mg.

Uses Disalcid is indicated in the treatment of chronic inflammatory conditions of joints, tendons, muscles and connective tissue – for example, osteoarthritis, rheumatoid arthritis, tendinitis, bursitis, fibrositis and polymyalgia.

Salsalate is an ester which after absorption is slowly hydrolysed to two molecules of free salicylic acid. Its insolubility in gastric juice renders it very unlikely to cause the gastric irritation, erosion and haemorrhage associated with acetylsalicylic acid. Moreover, its prolonged biological half-life is a real therapeutic advantage at night and in the relief of morning stiffness.

Dosage and administration *Adults:* 4 capsules daily in divided doses. Where a greater anti-inflammatory effect is required dosage may be increased to 2 capsules three or four times daily.

The last dose should be taken at bedtime. Disalcid should be taken immediately before or with food.

Children: Disalcid has not yet been evaluated in children. No dosage recommendation can therefore be made for children under the age of 12.

Contra-indications, warnings, etc

Side-effects: Allergic reactions may occur rarely with salsalate, as with other salicylates. If tinnitus and deafness occur they are usually signs of overdosage and are reversible by reducing dosage.

Caution: Although Disalcid is relatively free from the risk of gastric erosion usually associated with anti-inflammatory agents, caution should be observed in patients with active peptic ulcer.

Disalcid should be used with caution in patients with renal impairment.

Disalcid may enhance the activity of anticoagulants and hypoglycaemic agents.

Contra-indications: Disalcid is contra-indicated in patients with known hypersensitivity to salicylic acid or its derivatives.

Overdosage: Symptoms: Overdosage with Disalcid produces the usual symptoms of salicylism: tinnitus and deafness, vertigo, headache, sweating, hyperventilation and confusion are likely to occur.

Treatment: The stomach should be emptied by lavage with sodium bicarbonate or water.

Patients suffering from severe intoxication should in addition have forced alkaline diuresis by intravenous infusions of sodium bicarbonate solution. Haemodialysis or peritoneal dialysis may be needed in extreme cases, especially in the presence of cardiac or renal impairment.

Pharmaceutical precautions Disalcid should be stored in a cool, dry place. The container should be kept tightly closed.

Legal category POM.

Package quantities *Disalcid Capsules:* Bottles of 100.

Further information Nil.

Product licence number 0068/0089.

DORBANEX* DORBANEX* FORTE

Presentation Dorbanex is available in three forms – as capsules and two strengths of liquid.

Each yellow size 1 capsule, marked 'RIKER' contains:

Danthron BP	25 mg
Poloxamer 188	200 mg

Dorbanex Liquid is peach flavoured and orange coloured. Each 5 ml spoonful contains:

Danthron BP	25 mg
Poloxamer 188	200 mg

Dorbanex Forte is peach flavoured and orange coloured. Each 5ml spoonful contains:

Danthron BP	75 mg
Poloxamer 188	1,000 mg

Uses Dorbanex is indicated whenever a laxative needs to be prescribed for acute or chronic constipation. It is particularly useful in: painful defaecation associated with anal fissures, ulcers and haemorrhoids; restoring normal bowel habit in children and the elderly; post-operative patients and those confined to bed; pregnancy and the puerperium; preparation of patients for surgery and radiography; the prevention of faecal impaction; drug-induced constipation.

Dorbanex Forte is indicated for the patient with chronic, intractable constipation, or who may have become resistant to laxative treatment at normal dosage.

Poloxamer increases the penetration of water into faecal material, thus preventing the faecal mass from drying and hardening excessively. Faecal softening plus the surface activity of poloxamer has a useful lubricant effect on the gut content.

Poloxamer is not absorbed from the gut and does not directly stimulate peristalsis. It is excreted almost completely in the faeces.

Danthron is a synthetic anthraquinone compound, chemically related to emodin, the laxative principle of cascara, and to other anthraquinones which occur naturally in senna, rhubarb and aloes. It acts on the nerve endings of the myenteric plexus to stimulate the muscle of the large intestine.

Onset of effect is between six and twelve hours after administration.

Dosage and administration *Dorbanex Capsules:* *Adults:* One or two capsules.

Children: One capsule.

Before or after surgery or before radiography: 2 to 4 capsules.

Dorbanex Liquid: Adults: One or two 5 ml spoonfuls.

Children: A half to one 5 ml spoonful, as required.

Before or after surgery or before radiography: Two to four 5 ml spoonfuls.

Dorbanex Forte: Adults: One 5 ml spoonful, or as directed by the physician.

Dorbanex Forte is not recommended for children under 12 years.

Treatment should be taken at bedtime.

Contra-indications, warnings, etc

Side-effects: Danthron may cause temporary harmless pink or red colouring of the urine and perianal skin and, in prolonged use or high dosage, of the mucosa of the large intestine.

Caution: In some incontinent patients and in babies or children wearing napkins, Dorbanex may cause staining of the buttocks which may proceed to superficial sloughing of the skin. For this reason Dorbanex is not recommended for the treatment of infants and children in napkins, and should be used with caution in all incontinent patients.

Contra-indications: In common with other gastro-intestinal evacuants, Dorbanex should not be given when acute, painful conditions of the abdomen are present, or the cause of constipation is suspected to be intestinal obstruction.

Overdosage: Patients should be given plenty of fluids. An anticholinergic preparation such as atropine methonitrate would help to offset the excessive intestinal motility.

Pharmaceutical precautions No special storage precautions required.

Diluents: Tragacanth Mucilage BPC or Syrup BP should be used as diluents if required.

Attention is drawn to the fact that it is not possible to dilute Dorbanex Forte to fulfil prescriptions for Dorbanex because of the different ratio of the ingredients.

Legal category.

Dorbanex Forte 0068/5007

DUO-AUTOHALER*

Presentation Duo-Autohaler is a breath-actuated, pressurised aerosol for inhalation therapy. The vial contains a creamy-white suspension of isoprenaline hydrochloride 8 mg/ml and phenylephrine bitartrate 12 mg/ml in aerosol propellant, and delivers 400 measured doses, each containing 160 mcg isoprenaline hydrochloride and 240 mcg phenylephrine bitartrate.

Uses Duo-Autohaler is a potent bronchodilator, and is indicated for the immediate and prolonged relief of bronchospasm in bronchial asthma and chronic bronchitis.

Duo-Autohaler works differently from other inhalation aerosols in that it is operated by the intake of breath. This

means that each dose is delivered into the lungs at the right time in the breathing cycle, and that the amount of the dose inhaled is removed from the patient's control.

Isoprenaline is a directly acting sympathomimetic amine which activates both β_1 and β_2 adrenergic receptors. It has virtually no affinity for α -receptors. As a result it is a bronchodilator which also produces vasodilation in all blood vessels, including those of the pulmonary system. Pulse rate and cardiac output are increased, the degree of cardiac stimulation being proportional to the blood level. Isoprenaline is quickly eliminated from the blood and therefore has no cumulative effect. It inhibits histamine release in the lungs and has a beneficial effect on cilia and mucus flow.

By inhalation, isoprenaline has a rapid onset of bronchodilatation. Cardiac stimulation does not usually occur and the maximum possible bronchodilatation is produced at doses below those which result in significant tachycardia. Appreciable cardiac stimulation occurs only at the upper end of the therapeutic dose range.

Phenylephrine acts primarily on α -receptors. It complements and modifies the action of isoprenaline in several respects. It augments bronchodilatation. It delays the absorption of isoprenaline from the lungs and helps to prolong the bronchodilator activity. Phenylephrine also tends to offset cardiovascular effects of isoprenaline.

Paradoxically, the improved ventilation produced by bronchodilators is often accompanied by impairment of oxygenation of venous blood as it passes through the lungs, with consequent falls in arterial oxygen levels. This results from the non-selective relaxation of smooth muscle both of bronchioles and the pulmonary blood vessels. Phenylephrine opposes this effect and Duo-Autohaler is thus less likely to cause falls in the arterial oxygen tension than isoprenaline alone.

Dosage and administration Each puff from Duo-Autohaler delivers a measured dose of 160 mcg isoprenaline hydrochloride and 240 mcg phenylephrine bitartrate.

One, two or at the most three puffs should be sufficient to provide relief in most cases. It should not be necessary for the patient to take further treatment for at least 30 minutes, or more than eight treatments in any 24-hour period.

Children: Duo-Autohaler should be administered to children only under the supervision of a responsible adult.

Instructions for use: To obtain full benefit from Duo-Autohaler, the patient should follow these simple steps:

1. Shake the unit with the mouthpiece cover closed. Then open the mouthpiece cover downwards.

2. Breathe out as much as possible, then close the lips tightly round the mouthpiece. Keep the teeth apart and the tongue flat (to allow the flow of medicament into the lungs).

3. Suck in air through the mouthpiece as rapidly and deeply as possible. When the unit operates a click will be heard. Continue to breathe in after the click until the lungs are full. Hold the breath for a few seconds. Then take the inhaler away from the mouth and breath out slowly through pursed lips. If no click is heard, repeat step three, making sure that the lips are well sealed around the mouthpiece.

4. The unit must be reset before another dose can be taken by closing the mouthpiece cover upwards. It is important to keep the cover closed when the unit is not in use.

Contra-indications, warnings, etc

Side-effects: Overdosage may cause dry mouth, palpitations or nervousness.

Contra-indications: Duo-Autohaler should be used with caution in the presence of cardiac disease, hypertension or hyperthyroidism.

Overdosage: *Acute poisoning in non-asthmatics:* No cases have been reported. In the absence of details of such practical experience, the following guidance is based on theoretical considerations.

Symptoms: The toxic effects of isoprenaline (namely those of tachycardia, palpitations, peripheral vasodilatation and fall in blood pressure) are likely to be counterbalanced by the vasoconstrictor action of phenylephrine.

Treatment: General symptomatic therapy.

Chronic poisoning in asthmatics: No cases have been reported.

Excessive use of Duo-Autohaler during an attack of asthma indicates lack of response. This is a grave sign suggestive of status asthmaticus. It is recommended that 100 mg hydrocortisone be given immediately by intravenous injection, and the patient admitted to hospital without delay. Beta-blocking drugs should not be used.

Pharmaceutical precautions Duo-Autohaler should be stored in a cool place, protected from frost and sunlight. The shelf-life of Duo-Autohaler is three years.

The Duo-Autohaler vial is pressurised and therefore no attempt should be made to puncture it or to dispose of it by burning.

Legal category POM.

Package quantities Duo-Autohaler is supplied as complete units for which replacement cartridges are available. Each vial contains 400 doses.

Further information Nil.

Product licence number 0068/5012.

DUROPHET*

Presentation *7.5 mg strength:* Opaque white/white size 3 capsules printed 'RIKER'. Each capsule contains amphetamine 3.75 mg, dexamphetamine 3.75 mg, as ion-exchange resin complexes.

12.5 mg strength: Opaque white/charcoal grey size 3 capsules printed 'RIKER'. Each capsule contains amphetamine 6.25 mg, dexamphetamine 6.25 mg, as ion-exchange resin complexes.

20.0 mg strength: Opaque charcoal grey/charcoal grey size 3 capsules printed 'RIKER'. Each capsule contains amphetamine 10.0 mg, dexamphetamine 10.0 mg, as ion-exchange resin complexes.

Uses Durophet is an appetite-depressant and is indicated in all types of simple obesity.

Durophet contains laevo- and dextro-amphetamine in the ratio 1:3 as the anorectic agent. The amphetamines are present as ion-exchange resin complexes from which they are released in the gut over a period of about 10 hours. The extended absorption reduces the chance of side-effects and simplifies dosage. Each capsule provides 10–14 hours smooth anorectic effect.

Dosage and administration *Adults:* One capsule at breakfast. Administration can be delayed until mid-morning if an effect persisting well into the evening is required.

Children: Durophet is not recommended for children.

Contra-indications, warnings, etc

Side-effects: Dryness of the mouth, hyperactivity and other signs of mild central nervous stimulation may occur in some patients.

Cautions and contra-indications: Durophet is contra-indicated in patients under treatment with monoamine oxidase (MAO) inhibitors. It should be used with caution in severe hypertension and cardiovascular disease, and in patients hypersensitive to sympathomimetic agents.

Overdosage: *Symptoms:* These would be, initially, insomnia and irritability, but larger doses may give rise to fatigue, mental depression, an increase in blood pressure, fever, cardiovascular reactions, respiratory failure and cyanosis, disorientation, hallucinations, convulsions and coma.

Treatment: The stomach should be emptied by emesis or stomach tube and washed out with water if the preparation has been ingested within the last three or four hours.

If respiration is irregular or cyanosis is present, artificial respiration or oxygen should be given. The patient should be kept quiet and warm. For marked excitement, chlorpromazine 1–1.5 mg per kg body weight may be given intramuscularly or intravenously. Alternatively, a short-acting barbiturate, such as quinalbarbitone sodium or cyclobarbitone, should be given by mouth, or, if necessary, thiopentone sodium should be administered by intravenous injection. Providing renal function is adequate, elimination of amphetamine may be assisted by acidification of the urine with ammonium chloride in conjunction with an adequate fluid intake.

Pharmaceutical precautions No special storage precautions are required.

Legal category POM: MDA.

HUMAN ALBUMIN MICROSPHERES

Presentation Each Albumin Microsphere 99m Tc (instant microspheres) labelling vial contains 5 mg 3M Human Albumin Microspheres. The labelling vial and a radioactive warning label are the components of a single Albumin Microsphere 99m Tc Labelling Unit. The vial is a dry, sterile, pyrogen-free unit containing the microspheres, together with the necessary reagents for rapid and efficient labelling of the microspheres with 99m technetium. As manufactured, each vial contains 5 mg Albumin Microspheres, 6 mg Poloxamer 188 and tin (less than 50 mcg tin/mg microspheres).

Uses 3M Human Albumin Microspheres, labelled with 99m technetium are intended for gamma scintillation imaging of the lungs following intravenous administration or when injected into the dorsal pedal veins for combined radionuclide venography and lung scanning.

3M Human Albumin Microspheres are indicated as an adjunct to other diagnostic procedures whenever information about pulmonary circulation is required. The main uses are in the diagnosis of pulmonary embolism, chronic obstructive lung disease such as emphysema and chronic bronchitis, pathological conditions which impede pulmonary blood flow such as carcinoma and pulmonary abscess and other pulmonary diseases such as pneumonia and tuberculosis.

Combined radionuclide venography and imaging of the lungs is indicated as an adjunct to other diagnostic procedures where deep venous thrombosis in the lower extremities is suspected.

Dosage and administration The recommended adult dose range of 99m Tc-labelled Albumin Microspheres for lung scanning is 1–4 mCi (0.2–2 mg Albumin Microspheres) and for radionuclide venography it is 4–7 mCi (0.8–3.5 mg Albumin Microspheres).

In choosing the amount of 99m Tc radioactivity to be used in the preparation of the 99m Tc-labelled Albumin Microspheres, the labelling efficiency, number of patients, administered radioactive dose and radio-active decay must be taken into account. The recommended amount of 99m Tc radioactivity to be added to the labelling vial is 30 mCi. Assuming an average 99m Tc uptake of 95 per cent this will yield 5 mg of 99m Tc-labelled Albumin Microspheres with a specific activity of approximately 6 mCi/mg at the time of labelling and approximately 2 mCi/mg eight hours later.

The 99m Tc-labelled microspheres should be used within eight hours of labelling.

Lung imaging procedure: The suspension of 99m Tc-labelled Albumin Microspheres is administered by intravenous injection over a 10–20 second period using a plastic syringe.

Venography procedure: The following sequence is recommended for optimum imaging.

Camera area of view	Fraction of total dose (each foot)
Inferior Vena Cava and Iliac veins	1/4
Iliac and Femoral veins	1/8
Femoral and Popliteal veins	1/8

The procedure is completed with a lung scan.

For optimum results, patient studies should be completed within 60 minutes after administration of Albumin Microspheres.

Contra-indications, warnings, etc

Side-effects: Transient facial flushing and dyspnoea may occur in some patients. Less frequently, transient nausea, perspiration, and cyanosis may be encountered and, rarely, severe respiratory distress. The possibility of hypersensitivity reactions should be borne in mind after the administration of Albumin Microspheres, especially in patients who receive additional doses a number of weeks after the initial dose; these may be treated with corticosteroids, adrenaline and antihistamines.

Contra-indications: The safety of Albumin Microspheres in patients with a known right to left shunt has not been established and its use in such patients is contra-

indicated. The use of radiopharmaceuticals is contra-indicated in pregnant women, nursing mothers, or patients under 18 years of age unless exceptional circumstances exist.

Warning: The contents of the 3M Human Albumin Microspheres are not radioactive. However after 99m technetium is added, adequate shielding of the resulting preparation must be maintained.

Since 99m Tc is excreted in breast milk, breast feeding is not advised during treatment with Albumin Microspheres.

Overdosage: Not applicable.

Pharmaceutical precautions Instructions for the radioactive labelling of the Albumin Microspheres are included with each five unit kit of 3M Albumin Microspheres.

The shelf-life of Human Albumin Microspheres is one year.

Legal category POM.

Package quantities The complete product consists of the following items: Five 3M Microspheres (instant microspheres) Labelling Vials. Package insert. Technetium-99m labelling instructions.

Further information Nil.

Product licence number 0068/0041.

INTRALGIN®

Presentation Intralgin contains Benzocaine BP 2 per cent w/w and salicylamide 5 per cent w/w in an alcoholic vehicle. Intralgin is a clear, pleasant-smelling preparation – non-greasy and non-staining.

Uses Intralgin is indicated for the relief of muscle pain from strains, sprains and injuries, and pain associated with fibrositis, lumbago and non-articular rheumatism.

Intralgin combines two ingredients to relieve muscular aches and pains by absorption through the skin into the muscle.

Benzocaine is a widely used, well-tolerated local anaesthetic, acting rapidly on nerve endings. The action of the analgesic, salicylamide, is similar to that of salicylates.

The use of isopropyl alcohol as a vehicle for the medicaments contributes significantly to the action of Intralgin. Isopropyl alcohol because of its penetrative properties facilitates the percutaneous absorption of benzocaine and salicylamide so that they reach underlying tissue to relieve pain rapidly. Vigorous massage is not needed with 'Intralgin', unlike traditional rubs which rely for effect on erythema or counter-irritation.

Dosage and administration Intralgin Gel should be applied liberally and rubbed gently into the skin until penetration is complete. Vigorous massage is unnecessary.

For more rapid absorption the painful area should be warmed before applying 'Intralgin'.

Contra-indications, warnings, etc

Side-effects: Local sensitivity reactions to the benzocaine constituent have occasionally been reported.

Caution: If irritation or itching occurs due to hypersensitivity, Intralgin should be discontinued and a soothing cream applied.

Overdosage: Not applicable.

Pharmaceutical precautions The tube should be kept tightly closed and kept away from direct heat.

Legal category P.

Package quantities Tubes of 50 g.

Further information Nil.

Product licence number 0068/5076.

ISO-AUTOHALER*

Presentation Iso-Autohaler is a breath-actuated, pressurised aerosol for inhalation therapy. The vial contains a creamy-white suspension of Isoprenaline Sulphate BP 4 mg/ml in aerosol propellant, and delivers 400 measured doses, each containing 80 mcg Isoprenaline Sulphate BP.

Uses Iso-Autohaler is a potent bronchodilator, and is indicated for the relief of bronchospasm in bronchial asthma and chronic bronchitis.

Iso-Autohaler works differently from other inhalation aerosols in that it is operated by the intake of breath. This means that each dose is delivered into the lungs at the right time in the breathing cycle, and that the amount of the dose inhaled is removed from the patient's control.

Isoprenaline is a directly acting sympathomimetic amine which activates both the β_1 and β_2 adrenergic receptors. It has virtually no affinity for α -receptors. As a result it is a bronchodilator which also produces vasodilatation in all blood vessels, including those of the pulmonary system. Pulse rate and cardiac output are increased, the degree of cardiac stimulation being proportional to the blood level. Isoprenaline is quickly eliminated from the blood and therefore has no cumulative effect. It inhibits histamine release in the lungs and has a beneficial effect on cilia and mucus flow.

By inhalation, isoprenaline has a rapid onset of bronchodilatation. Cardiac stimulation does not usually occur and the maximum possible bronchodilatation is produced at doses below those which result in significant tachycardia. Appreciable cardiac stimulation occurs only at the upper end of the therapeutic dose range.

Dosage and administration Each puff from Iso-Autohaler delivers a measured dose of 80 mcg isoprenaline sulphate.

One, two or at the most three puffs should be sufficient to provide relief in most cases. It should not be necessary for the patient to take further treatment for at least 30 minutes, or more than eight treatments in any 24-hour period.

Children: Iso-Autohaler should be administered to children only under the supervision of a responsible adult.

Instructions for use: To obtain full benefit from Iso-Autohaler, the patient should follow these simple steps:

1. Shake the unit with the mouthpiece cover closed. Then open the mouthpiece cover downwards.

2. Breathe out as much as possible, then close the lips tightly round the mouthpiece. Keep the teeth apart and the tongue flat (to allow the flow of medicament into the lungs).

3. Suck in air through the mouthpiece as rapidly and deeply as possible. When the unit operates a click will be heard. Continue to breathe in after the click until the lungs are full. Hold the breath for a few seconds. Then take the inhaler away from the mouth and breathe out

slowly through pursed lips. If no click is heard, repeat step 3, making sure that the lips are well sealed around the mouthpiece.

4. The unit must be reset before another dose can be taken by closing the mouthpiece cover upwards. It is important to keep the cover closed when the unit is not in use.

Contra-indications, warnings, etc

Side-effects: Overdosage may cause dry mouth, palpitations or nervousness.

Contra-indications: Iso-Autohaler should be used with caution in the presence of cardiac disease, hypertension or hyperthyroidism.

Overdosage: Acute poisoning in non-asthmatics: No cases have been reported. In the absence of details of such practical experience, the following guidance is based on theoretical considerations.

Symptoms of acute isoprenaline poisoning are likely to be mainly cardiovascular effects, e.g. tachycardia, palpitations, peripheral vasodilation and a fall in blood pressure.

Treatment: General symptomatic therapy.

Chronic poisoning in asthmatics: Some cases have been reported, but no details of treatment have been given, other than withdrawal of the aerosol.

Excessive use during an attack of asthma indicates lack of response. This is a grave sign suggestive of status asthmaticus. It is recommended that 100 mg hydrocortisone be given immediately by intravenous injection, and the patient admitted to hospital without delay. Beta blocking drugs should not be used.

Pharmaceutical precautions Iso-Autohaler should be stored in a cool place, protected from frost and sunlight. The shelf-life of Iso-Autohaler is three years.

The Iso-Autohaler vial is pressurised and therefore no attempt should be made to puncture it or to dispose of it by burning.

Legal category POM.

Package quantities Iso-Autohaler is supplied as complete units for which replacement cartridges are available. Each vial contains 400 doses.

Further information Nil.

Product licence number 0068/5017.

LERGOBAN*

Presentation Creamy-white, circular, bi-convex tablets, 0.25 inch (6.4 mm) in diameter. The markings are 'LB' on one side and 'RIKER' on the other. Each Lergoban Tablet contains Diphenylpyraline Hydrochloride BP 5 mg.

Uses Lergoban is indicated in: allergic rhinitis, allergic conjunctivitis, angioneurotic oedema, hay fever, urticaria, allergic skin conditions and irritation.

Diphenylpyraline is an antihistamine with the general properties of antihistamine compounds, but with a low incidence of side-effects. In Lergoban its therapeutic usefulness is greatly increased by the long-acting presentation. Lergoban Tablets consist of a porous plastic matrix in which the diphenylpyraline is dispersed. In the gastro-intestinal tract, the active ingredient is gradually leached from the pores of the matrix and absorbed systemically. The release rate is not affected by

changes in pH, digestive enzymes, viscosity, surface tension or electrolyte concentration. The small plastic skeleton is insoluble and is excreted unchanged in the faeces.

The duration of effect from each dose of Lergoban is about 10 hours, so that only two doses every 24 hours are required.

Dosage and administration *Adults:* One or two 5 mg tablets every 12 hours, or as directed by the physician.

Children: Older children may be given one 5 mg tablet every 12 hours.

Lergoban is not recommended for children under 10 years.

Contra-indications, warnings, etc

Side-effects: Although side-effects are less likely with this sustained release tablet, slight drowsiness and dizziness, flushing, headache, anorexia and dryness of the mouth may occur.

Contra-indications: None.

Caution: Doses greater than those recommended may cause sedation and drowsiness. Patients undergoing treatment with an antihistamine should be warned of this possibility if they are in control of vehicles or machinery, where loss of attention may lead to accidents.

In some patients, the action of antihistamines may be potentiated by alcohol or other CNS depressants.

Overdosage: In adults, overdosage of antihistamines usually causes sedation, varying from drowsiness to deep sleep. Conversely in children, antihistamines often act as cerebral stimulants and may cause convulsions and hyperpyrexia. Stimulation may also occur in some adults.

Treatment: If the drug has recently been taken, the stomach should be emptied by gastric lavage, using a tube greater than 7 mm in diameter. Excitement may be controlled with diazepam given by mouth; the ECG should be monitored.

Pharmaceutical precautions No special storage precautions are required.

Legal category P.

Package quantities Bottles of 50 and 200 tablets.

Further information Nil.

Product licence number 0068/5002.

MEDIHALER-DUO*

Presentation Medihaler-duo is a pressurised aerosol for inhalation therapy. The vial contains a creamy-white suspension of isoprenaline hydrochloride 8 mg/ml and phenylephrine bitartrate 12 mg/ml in aerosol propellant, and delivers 400 measured doses each containing 160 mcg isoprenaline hydrochloride and 240 mcg phenylephrine bitartrate.

Uses Medihaler-duo is a potent bronchodilator and is indicated for the immediate and prolonged relief of bronchospasm in bronchial asthma and chronic bronchitis.

Isoprenaline is a directly acting sympathomimetic amine which activates both β_1 and β_2 adrenergic receptors. It has virtually no affinity for α -receptors. As a result it is a bronchodilator which also produces

vasodilatation in all blood vessels, including those of the pulmonary system. Pulse rate and cardiac output are increased, the degree of cardiac stimulation being proportional to the blood level. Isoprenaline is quickly eliminated from the blood and therefore has no cumulative effect. It inhibits histamine release in the lungs and has a beneficial effect on cilia and mucus flow.

By inhalation, isoprenaline has a rapid onset of bronchodilatation. Cardiac stimulation does not usually occur and the maximum possible bronchodilatation is produced at doses below those which result in significant tachycardia. Appreciable cardiac stimulation occurs only at the upper end of the therapeutic dose range.

Phenylephrine acts primarily on α -receptors. It complements and modifies the action of isoprenaline in several respects. It augments bronchodilatation. It delays the absorption of isoprenaline from the lungs and helps to prolong the bronchodilator activity. Phenylephrine also tends to offset the cardiovascular effects of isoprenaline.

Paradoxically, the improved ventilation produced by bronchodilators is often accompanied by impairment of oxygenation of venous blood as it passes through the lungs, with consequent falls in arterial oxygen levels. This results from the non-selective relaxation of smooth muscle both of bronchioles and the pulmonary blood vessels. Phenylephrine opposes this effect and Medihaler-duo is thus less likely to cause falls in the arterial oxygen tension than isoprenaline alone.

Dosage and administration Each puff from Medihaler-duo delivers a measured dose of 160 mcg isoprenaline hydrochloride and 240 mcg phenylephrine bitartrate. One, two or at the most three puffs should be sufficient to provide relief in most cases. It should not be necessary for the patient to take further treatment for at least 30 minutes or more than eight treatments in any 24-hour period.

Correct technique is essential if the patient is to obtain full benefit from each treatment. Probably the most reliable way of ensuring this is for the doctor to show the patient how to use 'Medihaler-duo' by personal demonstration, using a Demonstration Unit containing no active medicament. These units are available on request.

Children: Medihaler-duo should be administered to children only under the supervision of a responsible adult.

Instructions for use: With the dust cap removed, Medihaler-duo should be shaken to disperse the particles of medicament in the propellant.

The mouthpiece should then be placed well into the mouth and the lips closed firmly around it. (When the adapter is held at the correct angle, the spray will go to the back of the throat and down into the lungs.) The patient should now breathe out fully through the adapter.

As soon as the patient starts to breathe in, the vial should be pressed firmly down into the adapter. This releases a dose.

The adapter should now be taken from the mouth and the inspired breath held for as long as possible to avoid exhaling particles of medicament.

Before taking a further inhalation, the patient should wait at least one minute to allow the full effect of the puff to become apparent.

Contra-indications, warnings, etc

Side-effects: Overdosage may cause dry mouth, palpitations or nervousness.

Contra-indications: Medihaler-duo should be used with caution in the presence of cardiac disease, hypertension or hyperthyroidism.

Overdosage: Acute poisoning in non-asthmatics: No cases have been reported. In the absence of details of such practical experience, the following guidance is based on theoretical considerations.

Symptoms: The toxic symptoms of isoprenaline (namely those of tachycardia, palpitations, peripheral vasodilatation and fall in blood pressure) are likely to be counterbalanced by the vasoconstrictor action of phenylephrine.

Treatment: General symptomatic therapy.

Chronic poisoning in asthmatics: No cases have been reported. However, excessive use of Medihaler-duo during an attack of asthma indicates lack of response. This is a grave sign suggestive of status asthmaticus. It is recommended that 100 mg hydrocortisone be given immediately by intravenous injection, and the patient admitted to hospital without delay. Beta blocking drugs should not be used.

Pharmaceutical precautions Medihaler-duo should be stored in a cool place, protected from frost and sunlight. The shelf-life of Medihaler-duo is three years.

As the Medihaler vial is pressurised, no attempt should be made to puncture it or to dispose of it by burning.

Legal category POM.

Package quantities Standard pack (complete unit): vial contains 400 doses.

Further information Nil.

Product licence number 0068/5070.

MEDIHALER-EPI*

Presentation Medihaler-epi is a pressurised aerosol for inhalation therapy. The vial contains a creamy-white suspension of Adrenaline Acid Tartrate BP 14 mg/ml in aerosol propellant, and delivers 400 measured doses, each containing 280 mcg Adrenaline Acid Tartrate BP.

Uses Medihaler-epi is a potent bronchodilator, and is indicated for the relief of bronchospasm in bronchial asthma, chronic bronchitis and drug sensitivity reactions.

Adrenaline is a sympathomimetic amine which activates both α - and β -adrenergic receptors. As a result, it causes vasoconstriction, bronchodilatation, relieves mucosal congestion and is a cardiac stimulant.

By inhalation adrenaline relaxes bronchial smooth muscle and constricts bronchial mucosal vessels, relieving congestion and oedema. However, tolerance to adrenaline can develop after repeated use and the action of adrenaline in reducing bronchial secretion may make mucus more viscid.

Dosage and administration Each puff from Medihaler-epi delivers a measured dose of 280 mcg adrenaline acid tartrate. One, two or at the most three puffs should be sufficient to provide relief in most cases. It should not be necessary for the patient to take further treatment for at least 30 minutes or more than eight treatments in any 24-hour period.

Correct technique is essential if the patient is to obtain full benefit from each treatment. Probably the most reliable way of ensuring this is for the doctor to show the

patient how to use Medihaler-epi by personal demonstration, using a Demonstration Unit containing no active medicament. These units are available on request.

Children: Medihaler-epi should be administered to children only under the supervision of a responsible adult.

Instructions for use: With the adapter dust cap removed, Medihaler-epi should be shaken to disperse the particles of medicament in the propellant.

The mouthpiece should then be placed well into the mouth and the lips closed firmly around it. (When the adapter is held at the correct angle, the spray will go right to the back of the throat and down into the lungs.) The patient should now breathe out fully through the adapter.

As soon as the patient starts to breathe in, the vial should be pressed firmly down into the adapter. This releases a dose.

The adapter should now be taken from the mouth and the inspired breath held for as long as possible to avoid exhaling particles of medicament.

Before taking a further inhalation, the patient should wait at least one minute to allow the full effect of the puff to become apparent.

Contra-indications, warnings, etc

Side-effects: Overdosage may cause dry mouth, palpitations or nervousness.

Contra-indications: Medihaler-epi should be used with caution in the presence of cardiac disease, hypertension or hyperthyroidism.

Prolonged use of adrenaline may lead to the development of tolerance (adrenaline 'fastness'). When this occurs, isoprenaline is a most effective alternative.

Overdosage: Acute poisoning in non-asthmatics: No cases have been reported. The following guidance is based on acute adrenaline poisoning following parenteral administration.

Symptoms: Restlessness, palpitations, rapid pulse, tremor, weakness, dizziness, headache, coldness of extremities; elevated blood pressure, tachycardia; the symptoms are rapid in onset and of short duration.

Treatment: It is essential to administer immediately intravenous injections of quick-acting sympatholytics, e.g. phentolamine or piperoxan.

Chronic poisoning in asthmatics: Some cases have been reported, but no details of treatment have been given, other than withdrawal of the aerosol.

Excessive use of Medihaler-epi during an attack of asthma indicates lack of response. This is a grave sign suggestive of status asthmaticus. It is recommended that 100 mg hydrocortisone be given immediately by intravenous injection, and the patient admitted to hospital without delay. Beta-blocking drugs should not be used.

Pharmaceutical precautions Medihaler-epi should be stored in a cool place, protected from frost and sunlight. The shelf-life of Medihaler-epi is three years.

As the Medihaler vial is pressurised, no attempt should be made to puncture it or to dispose of it by burning.

Legal category POM.

Package quantities Standard pack (complete unit): vial contains 400 doses.

Further information Nil.

Product licence number 0068/5060.

MEDIHALER-ISO* MEDIHALER-ISO* FORTE

Presentation Medihaler-iso and Medihaler-iso Forte are pressurised aerosols for inhalation therapy.

The Medihaler-iso vial contains a creamy-white suspension of Isoprenaline Sulphate BP 4 mg/ml in aerosol propellant and delivers 400 measured doses, each containing 80 mcg Isoprenaline Sulphate BP.

The Medihaler-iso Forte vial contains a creamy-white suspension of Isoprenaline Sulphate BP 20 mg/ml in aerosol propellant, and delivers 400 measured doses, each containing 400 mcg Isoprenaline Sulphate BP.

Uses Medihaler-iso and Medihaler-iso Forte are potent bronchodilators, and are indicated for the relief of bronchospasm in bronchial asthma and chronic bronchitis.

Isoprenaline is a directly acting sympathomimetic amine which activates both β_1 and β_2 adrenergic receptors. It has virtually no affinity for α -receptors. As a result it is a bronchodilator which also produces vasodilatation in all blood vessels, including those of the pulmonary system. Pulse rate and cardiac output are increased, the degree of cardiac stimulation being proportional to the blood level. Isoprenaline is quickly eliminated from the blood and therefore has no cumulative effect. It inhibits histamine release in the lungs and has a beneficial effect on cilia and mucus flow.

By *inhalation*, isoprenaline has a rapid onset of bronchodilatation. Cardiac stimulation does not usually occur and the maximum possible bronchodilatation is produced at doses below those which result in significant tachycardia. Appreciable cardiac stimulation occurs only at the upper end of the therapeutic dose range.

Dosage and administration Each puff from Medihaler-iso delivers a measured dose of 80 mcg isoprenaline sulphate; and from Medihaler-iso Forte, 400 mcg isoprenaline sulphate. One, two or at the most three puffs should be sufficient to provide relief in most cases. It should not be necessary for the patient to take further treatment for at least 30 minutes, or more than eight treatments in any 24-hour period.

Correct technique is essential if the patient is to obtain full benefit from each treatment. Probably the most reliable way of ensuring this is for the doctor to show the patient how to use Medihaler by personal demonstration, using a Demonstration Unit containing no active medicament. These units are available on request.

Children: Medihaler-iso should be administered to children only under the supervision of a responsible adult. Medihaler-iso Forte is not recommended for children.

Instructions for use: With the adapter dust cap removed, Medihaler should be shaken to disperse the particles of medicament in the propellant.

The mouthpiece should then be placed well into the mouth and the lips closed firmly around it. (When the adapter is held at the correct angle, the spray will go right to the back of the throat and down into the lungs.) The patient should now breathe out fully through the adapter.

As soon as the patient starts to breathe in, the vial should be pressed firmly down into the adapter. This releases a dose.

The adapter should now be taken from the mouth and the inspired breath held for as long as possible to avoid exhaling particles of medicament.

Before taking a further inhalation, the patient should

wait at least one minute to allow the full effect of the puff to become apparent.

Contra-indications, warnings, etc

Side-effects: Overdosage may cause dry mouth, palpitations or nervousness.

Contra-indications: Medihaler-iso and Medihaler-iso Forte should be used with caution in the presence of cardiac disease, hypertension or hyperthyroidism.

Overdosage: *Acute poisoning in non-asthmatics:* No cases have been reported. In the absence of details of such practical experience, the following guidance is based on theoretical considerations.

Symptoms of acute isoprenaline poisoning are likely to be mainly cardiovascular effects, e.g. tachycardia, palpitations, peripheral vasodilation and a fall in blood pressure.

Treatment: General symptomatic therapy.

Chronic poisoning in asthmatics: Some cases have been reported, but no details of treatment have been given, other than withdrawal of the aerosol.

Excessive use during an attack of asthma indicates lack of response. This is a grave sign suggestive of status asthmaticus. It is recommended that 100 mg hydrocortisone be given immediately by intravenous injection, and the patient admitted to hospital without delay. Beta blocking drugs should not be used.

Pharmaceutical precautions Medihaler-iso and Medihaler-iso Forte should be stored in a cool place, protected from frost and sunlight. The shelf-life of Medihaler-iso and Medihaler-iso Forte is three years.

As the Medihaler vial is pressurised, no attempt should be made to puncture it or to dispose of it by burning.

Legal category POM.

Package quantities Standard pack (complete unit): vial contains 400 doses.

Medihaler-iso Forte	0068/5072

NORFLEX*

Presentation *Injection:* Each 2 ml ampoule contains Orphenadrine Citrate BP 30 mg/ml.

Tablets: White, circular, bi-convex tablets, 8.8 mm diameter, marked 'N/X' on one side and 'RIKER' on the reverse. Each tablet contains Orphenadrine Citrate BP 100 mg in a slow-release base.

Uses Norflex is indicated for the relief of acute skeletal muscle spasm associated with muscle injury, sprains and strains, prolapsed intervertebral disc, 'whiplash' injuries, fractures before and after reduction and immobilisation, acute torticollis and hiccough.

Orphenadrine acts centrally by blocking reticular facilitation, i.e. it blocks preferentially those pathways whose hyperactivity leads to an exaggeration of motor function such as spasticity, rigidity or muscle spasm.

Norflex is a potent skeletal muscle relaxant which provides relief of acute muscle spasm and associated pain. It relaxes only muscle in spasm without impairment of normal muscle tone or voluntary movement. Action is rapid in onset, particularly in the case of Norflex Injection, and relatively prolonged. The effect of orphenadrine on

skeletal muscle spasm has been demonstrated objectively by means of electromyography.

Dosage and administration *Parenteral*: 60 mg (one 2 ml ampoule) administered intramuscularly or intravenously. Further 60 mg doses may be given at 12-hour intervals, if required.

Note: An intravenous injection should be administered over a period of about five minutes.

Oral: 2 tablets daily, 1 in the morning and 1 in the evening. This may be increased to 3 tablets daily if required.

Norflex is not recommended for children under 12 years.

Contra-indications, warnings, etc

Side-effects: Dry mouth, nausea, blurring of vision, dizziness and restlessness may occur in some patients susceptible to the parasympatholytic action of orphenadrine. These symptoms rapidly disappear following reduction of dosage or cessation of treatment. Some patients may experience a transient feeling of light-headedness or dizziness following an injection of Norflex.

Caution: Norflex should be used with caution in patients with tachycardia.

Contra-indications: Contra-indications to Norflex result from the parasympatholytic action of orphenadrine. Norflex should not be given to patients with glaucoma, urinary retention (e.g. due to prostatic hypertrophy or obstruction of the bladder neck) and myasthenia gravis.

Overdosage: Symptoms of orphenadrine citrate overdosage: Excitement, confusion and delirium leading to coma, convulsions, tachycardia. Dilated pupils and urinary retention may occur.

Treatment: Gastric lavage should be carried out immediately regardless of the estimated ingested dose. Convulsions and delirium respond to relatively large doses of diazepam, preferably by mouth. Adequate hydration of the patient is important.

Pharmaceutical precautions No special storage precautions are required.

Legal category POM.

Package quantities *Ampoules (30 mg/ml)*: 3 × 2 ml. *Tablets*: Bottles of 100.

Further information Nil.

Product licence numbers

Norflex Tablets 0068/5008
Norflex Injection 0068/5078

NORGESIC*

Presentation A white or almost white, circular, compressed tablet 12.8 mm diameter. Markings are 'N/G' on one side and 'RIKER' on the other. Each tablet contains Orphenadrine Citrate BP 35 mg and Paracetamol BP 450 mg.

Uses Norgesic is indicated for the relief of painful skeletal muscle spasm associated with chronic low back pain, sprains and strains, prolapsed intervertebral disc, muscle injury, non-articular rheumatism (fibrositis, myositis and myalgia), 'whiplash' injuries, acute torticollis, tension headache, dysmenorrhoea, other acute or chronic painful muscular conditions.

Orphenadrine acts centrally by blocking reticular

facilitation, i.e. it blocks preferentially those pathways whose hyperactivity leads to an exaggeration of motor function such as spasticity, rigidity or muscle spasm. Orphenadrine relaxes only muscle in spasm without impairment of normal muscle tone or voluntary movement. Action is rapid in onset and relatively prolonged. The effect of orphenadrine on skeletal muscle spasm has been demonstrated objectively by means of electromyography.

Paracetamol is a well-tolerated analgesic and antipyretic. Its analgesic action is rapid in onset (within 30 minutes) and lasts for three to four hours. It has been found to be particularly effective for the relief of pain in muscles and joints.

Paracetamol does not produce gastric upset or bleeding. Hepatic and renal necrosis have been associated with the ingestion of paracetamol in amounts greatly in excess of normal therapeutic dosage.

Dosage and administration *Adults*: Two tablets three times a day.

Norgesic is not recommended for children under 12 years old.

Contra-indications, warnings, etc

Side-effects: Dry mouth, nausea, blurring of vision, dizziness and restlessness may occur in some patients susceptible to the parasympatholytic action of orphenadrine. These symptoms disappear rapidly following reduction of dosage or withdrawal of treatment.

Contra-indications: Contra-indications to Norgesic result from the parasympatholytic action of orphenadrine. Norgesic should not be given to patients with glaucoma, urinary retention (e.g. due to prostatic hypertrophy or obstruction of the bladder neck) or myasthenia gravis. It should be used with caution in patients with tachycardia.

Overdosage: Symptoms of orphenadrine citrate overdosage are excitement, confusion, and delirium leading to coma. Convulsions, tachycardia, dilated pupils and urinary retention may occur.

Paracetamol overdosage may cause acute liver damage but symptoms may not appear for up to several days after ingestion.

Treatment: Gastric lavage should be carried out immediately, regardless of the estimated ingested dose. Convulsions and delirium respond to relatively large doses of diazepam, preferably by mouth. Adequate hydration of the patient is important. It is recommended that the patient be referred to a hospital where early and regular monitoring of plasma paracetamol levels can be carried out. If instituted sufficiently early, treatment with N-acetylcysteine, L-methionine or L-cysteamine will minimise liver damage.

Pharmaceutical precautions No special storage precautions are required.

Legal category POM.

Package quantities Bottles of 100 and 500 tablets.

Further information Nil.

Product licence number 0068/5059.

NUELIN*

Presentation White, circular, biconvex tablet with breakline, 9 mm in diameter, marked NL/125 on one side and 'RIKER' on the other.

Each Nuelin tablet contains Theophylline BP 125 mg in microcrystalline form.

Uses Nuelin is indicated for the relief of bronchospasm.

Theophylline is well established in the treatment of bronchospasm. In Nuelin, the theophylline is present as microfine particles to give a very high rate of dissolution which results in rapid and predictable absorption.

Dosage and administration *Adults:* One tablet three or four times daily; this can be increased to two tablets three or four times daily depending on response.

Children: 7–12 years (20–35 kg): Half or 1 tablet three or four times daily.

The difficulty of dividing the tablet accurately makes Nuelin unsuitable for use in children under the age of seven.

Nuelin tablets are soluble in water.

Contra-indications, warnings, etc

Side-effects: Nausea or other gastric distress may occur rarely. Palpitations and insomnia have been reported occasionally.

Contra-indications: There are no known contra-indications to theophylline therapy.

Overdosage: Symptoms: Characterised by nausea, vomiting and gastro-intestinal irritation. Tachycardia and hypotension may also occur.

Treatment: Gastric lavage and general supportive measures are recommended.

Pharmaceutical precautions The tablets should be stored at a temperature not exceeding 30°C. The container should be kept tightly closed.

Legal category P.

Package quantities Bottles of 100 tablets.

Further information Nil.

Product licence number 0068/0064.

NUELIN* LIQUID

Presentation Clear, light brown, pleasantly flavoured liquid. Each 5 ml dose of Nuelin Liquid contains theophylline sodium glycinat 120 mg equivalent to Theophylline Hydrate BP 60 mg.

Uses Nuelin Liquid is indicated for the relief of bronchospasm. Nuelin in tablet form (microcrystalline theophylline 125 mg) is established as a highly effective bronchodilator. Nuelin Liquid is designed to offer comparable relief of bronchospasm with the same low incidence of side-effects, for patients who prefer a liquid presentation. Each 10 ml of Nuelin Liquid approximates to one 125 mg Nuelin tablet.

Dosage and administration *Adults:* 10–20 ml (two to four 5 ml spoonfuls) three or four times daily.

Children: 7–12 years: One-and-a-half or two 5 ml spoonfuls three or four times daily.

2–6 years: One or one-and-a-half 5 ml spoonfuls three or four times daily.

Under 2 years: It is recommended that dosage is calculated at 5 mg/kg theophylline hydrate per dose (0.4 ml/kg Nuelin Liquid) and given three or four times daily. Nuelin Liquid may be diluted with Syrup BP if required.

Contra-indications, warnings, etc

Contra-indications: There are no known contra-indications to theophylline therapy.

Side-effects: Nausea or other gastric distress may occur rarely. Palpitations and insomnia have been reported occasionally.

Overdosage: Symptoms: Nausea, vomiting and gastro-intestinal irritation.

Treatment: Gastric lavage and general supportive measures are recommended.

Pharmaceutical precautions No special storage precautions are required.

The shelf-life of Nuelin Liquid is two years.

Legal category P.

Package quantities Bottles of 500 ml.

Further information Each 5 ml spoonful of Nuelin Liquid contains 0.38 mEq sodium (8.7 mg Na).

Product licence number 0068/0084.

NUELIN* SA

Presentation *Nuelin SA:* White, biconvex, round tablets, 9 mm in diameter and marked NLS 175 on one side and RIKER on the other.

Each Nuelin SA tablet contains 175 mg anhydrous theophylline in a slow release formulation which gives a particularly smooth release of medicament over a prolonged period.

Nuelin SA-250: White, biconvex, round tablets with breakline, 11 mm in diameter and marked NLS 250 on one side and RIKER on the other. Each Nuelin SA-250 tablet contains 250 mg anhydrous theophylline in a slow release formulation.

Uses Nuelin SA and Nuelin SA-250 tablets are indicated for the treatment and prophylaxis of bronchospasm.

Because effective plasma levels are maintained for up to twelve hours from a single dose, less frequent dosing is required than with conventional theophylline preparations.

Dosage and administration *Nuelin SA: Adults:* One tablet twice daily, increasing to two tablets twice daily if necessary.

Children: 6 to 12 years: one tablet twice daily.

Nuelin SA-250: Adults: One tablet twice daily, increasing to two tablets twice daily if necessary.

Children: 6 to 12 years: Half or one tablet twice daily.

Nuelin SA and Nuelin SA-250 tablets are not recommended for children under six years.

Nuelin SA tablets should be swallowed whole and not crushed or chewed.

Nuelin SA-250 tablets are scored and may be halved but should not be crushed or chewed.

Contra-indications, warnings, etc

Side-effects: The side-effects commonly associated with xanthine derivatives such as nausea, gastric irritation, palpitations and insomnia are much diminished when a sustained action preparation such as Nuelin SA is used.

Caution: In the case of an acute asthmatic attack in a patient receiving a sustained action theophylline preparation, great caution must be taken when administering

intravenous aminophylline. Half the recommended loading dose of aminophylline (generally 6 mg/kg) should be given i.e. 3 mg/kg, cautiously.

Contra-indications: There are no known contra-indications to theophylline therapy.

Overdosage: Symptoms: Nausea, vomiting and gastric irritation. Tachycardia and hypotension may also occur.

Treatment: Gastric lavage and general supportive measures are recommended.

Pharmaceutical precautions No special storage precautions are required.

Legal category P.

Package quantities *Nuelin SA:* Bottles of 100 tablets.
Nuelin SA-250: Bottles of 100 tablets.

Further information Nil.

Product licence numbers

Nuelin SA 0068/0092
Nuelin SA-250 0068/0093

NUMOTAC*

Presentation White to creamy-white, circular bi-convex tablets 7.15 mm diameter, marked 'NT' on one side and 'RIKER' on the other. Each tablet contains isoetharine hydrochloride 10 mg in a porous plastic matrix.

Uses Numotac is indicated for the relief of bronchospasm in chronic bronchitis, bronchial asthma and pulmonary emphysema.

Isoetharine is a sympathomimetic amine with a marked bronchodilator action. It is rapidly absorbed from the gastro-intestinal tract and has a relatively fast onset of action.

A notable feature of isoetharine is that at normal dosage levels it acts selectively on the β_2 -receptors of bronchial muscle and has little effect on the β_1 cardiac receptors. Cardiac side-effects are therefore reduced to negligible levels, and occur only at higher doses or in hypersensitive patients.

Numotac contains isoetharine hydrochloride embedded in a porous plastic matrix. By this means, the release of isoetharine is controlled, giving Numotac a duration of action of between four and six hours. This formulation reduces the possibility of side-effects associated with uneven blood levels.

Dosage and administration *Adults:* One or two tablets three or four times daily.

For patients who have not previously been prescribed oral bronchodilator therapy or who are known to be sensitive to the action of sympathomimetic amines, treatment should be started on the lower dosages (3 or 4 tablets daily). Dosage may then be adjusted upwards, if necessary, to achieve optimum response.

Clinical and pharmacological studies have shown that 'Numotac' acts for between four and six hours. In susceptible patients administration at shorter intervals may give rise to side-effects. When this occurs dosage should be adjusted accordingly.

Children: The 10 mg tablet should not be broken, and this dose is not recommended for children aged 12 years or under.

Contra-indications, warnings, etc

Side-effects: With higher doses, or in persons sensitive

to sympathomimetic amines, tachycardia, palpitations, tremor or vertigo may occur.

Cautions and contra-indications: Numotac should be used with caution in the presence of cardiac disease, or hypertension. The use of Numotac is contra-indicated in thyrotoxicosis.

Overdosage: Symptoms: The blood pressure may fall and cause dizziness and fainting. Other symptoms may include headache, nervousness, tremor and weakness.

Treatment: General symptomatic treatment. If the drug has recently been taken, the stomach should be emptied by gastric lavage, using a tube greater than 8 mm in diameter.

Pharmaceutical precautions No special storage precautions are required.

Legal category POM.

Package quantities Bottles of 100 and 500 tablets.

Further information Nil.

Product licence number 0068/5054.

PENTOXYLON*

Presentation Reddish-brown, circular, bi-convex tablets marked 'P/X' on one side and 'RIKER' on the other. Diameter 8.0 mm. Each Pentoxylon Tablet contains Rauwiloid brand of alkaloid hydrochlorides of *Rauwolfia serpentina* 1 mg and pentaerythritol tetranitrate 10 mg.

Uses Pentoxylon is indicated for the prophylaxis of angina pectoris.

Pentaerythritol tetranitrate (PETN) is an organic nitrate which produces a prolonged dilatation of the coronary blood vessels, consequently reducing the incidence and severity of angina attacks.

Rauwiloid produces a moderate fall in blood pressure (more particularly in cases where it is raised), bradycardia and a general feeling of well-being.

Dosage and administration *Adults:* One or two tablets four times daily between meals.

Pentoxylon is not recommended for children.

Contra-indications, warnings, etc

Side-effects: Occasional headache may occur due to the pentaerythritol tetranitrate. Some nasal stuffiness and looseness of the bowel may occur. There might also be a slight increase in appetite and an increase in weight. As with other Rauwolfia preparations, the possibility of mental depression must be considered. However, serious mental depression has not been reported as a result of Rauwiloid therapy.

Contra-indications: There are no absolute contra-indications to the use of Pentoxylon. It should, however, be administered with caution to patients who have a history of depression or peptic ulcer.

Overdosage: Symptoms: Mild overdosage can produce nasal congestion, gastro-intestinal upset such as vomiting and diarrhoea, drowsiness, apathy, fatigue, headache, vertigo, hallucinations.

Higher doses may cause flushing, insomnia, vasodilatation, bradycardia, severe depression, sodium retention, oedema, peptic ulceration.

After a single massive dose most of the effects are not encountered. Instead, the patient becomes sleepy and eventually comatose. Coma may last for several days.

Treatment: In the acutely poisoned patient, who is not in a coma, an emetic should be administered, or gastric lavage performed, even several hours after ingestion of the alkaloid. A saline cathartic should be left in the stomach. Nasal congestion, excessive salivation, gastro-intestinal upsets and other parasympathetic side-effects may be controlled by small doses of atropine.

Epigastric pain and peptic ulcer may be treated with local antacid therapy.

Unless the blood pressure becomes very low, vasopressor drugs which may prove inactive (e.g. ephedrine) or which may lead to exaggerated cardiovascular response (e.g. adrenaline or noradrenaline) should be avoided. Blankets and external application of mild heat should be used to maintain normal body temperature. If coma with hypotension occurs, conservative supportive therapy should be employed. In general, supportive measures that do not involve extensive drug therapy are probably safest, and are expected to suffice in most cases.

In cases of methaemoglobinaemia and syncope, intravenous injection of methylene blue (1–2 mg/kg body weight) can be given.

Pharmaceutical precautions No special storage precautions are required.

Legal category POM.

Package quantities Bottle of 100 tablets.

Further information Nil.

Product licence number 0068/5073.

PEPTARD*

Presentation Creamy-white, circular, biconvex tablet, 7 mm in diameter. The markings are 'RIKER' on one side, and letters 'PTD' on the other. Each Peptard tablet contains 1-hyoscyamine sulphate 200 mcg.

Uses Peptard is indicated for the treatment of peptic ulcer, irritable colon, hyperhidrosis and conditions in which the oral administration of an antispasmodic/antisecretory agent is beneficial.

Naturally occurring atropine consists of a racemic mixture of hyoscyamine isomers of which the l-isomer has the greater physiological activity. With l-hyoscyamine it is possible to adjust the dose more readily to obtain a selective action on the gastro-intestinal tract with fewer anticholinergic side-effects than with atropine.

l-Hyoscyamine reduces the volume of gastric secretion and total acid output. Secretion during both psychic and gastric phases is reduced, but not abolished. A decrease in pepsin output contributes to the overall effects.

In Peptard, the slow release of l-hyoscyamine sulphate from the plastic matrix provides more even blood levels and response.

Dosage and administration *Adults:* In general, two or three tablets (400–600 mcg) twice daily.

Children: Older children (over 10 years) one or two tablets twice daily.

Individual cases may be increased, for example, with peptic ulcer therapy, up to 3 mg a day in three divided doses.

The tablets should be swallowed whole.

Contra-indications, warnings, etc

Side-effects: At the optimum effective dose, the only side-effects that have occurred are dry mouth, slight visual disturbance and occasional hesitancy of micturition.

Contra-indications: Peptard should not be given to patients with, or suspected of suffering from glaucoma or with obstruction of the neck of the urinary bladder, pyloric stenosis or myasthenia gravis.

Overdosage – Symptoms: The main symptoms of toxicity are dryness of mucous membranes and intense thirst, dilation of pupils and blurred vision, a hot, dry skin, with or without a rash, hyperpyrexia, tachycardia, palpitations and elevated blood pressure, urinary urgency and hesitation; and restlessness, excitement and confusion.

Treatment: If the drug has recently been taken, the stomach should be emptied by gastric lavage, using a tube greater than 7 mm in internal diameter. Symptomatic treatment should be given.

Pharmaceutical precautions The tablets should be stored at room temperature.

The shelf-life of Peptard is two years.

Legal category POM.

Package quantities Bottles of 100 tablets.

Further information Nil.

Product licence number 0068/0054.

PHOLTEX*

Presentation Each 5 ml dose contains Pholcodine BP 15 mg and phenyltoloxamine 10 mg as ion-exchange resin complexes in a pleasantly flavoured, orange-coloured, thixotropic vehicle.

Uses For prolonged antitussive action.

Pholtex is well accepted by children and is valuable in the treatment of whooping cough and the cough associated with measles.

Pholtex contains the cough depressant pholcodine, the action of which is potentiated and reinforced by the antihistamine phenyltoloxamine. Both are presented as ion-exchange resin complexes to give smooth and prolonged effect.

Phenyltoloxamine complements the action of pholcodine not only because it potentiates the activity of the cough depressant but also because of its antihistaminic and antispasmodic actions which help to relieve associated symptoms.

The cough-depressant action of Pholtex is maintained for up to 10 hours with a single 5 ml dose. Consequently, a dose taken on retiring and another on rising should provide effective relief of cough throughout the day and night in most cases.

Dosage and administration *Adults:* One 5 ml dose two or three times daily.

Children: Half to full adult dosage, according to age.

Pholtex contains no sugar and is therefore suitable for cough treatment in diabetic patients.

Contra-indications, warnings, etc

Side-effects: In common with all preparations which contain antihistamines, Pholtex may cause drowsiness, although this is very unlikely to occur in the recommended dosage.

Contra-indications: None.

Overdosage: The symptoms of antihistamine over-dosage would probably predominate. These include nausea and vomiting, diarrhoea, colic and epigastric pain. Overdosage may cause sedation, but large doses could cause convulsions and hyperpyrexia, particularly in children.

Treatment: The stomach should be emptied by aspiration and lavage. The respiration may require assistance. The patient, particularly if a child, should be kept quiet.

Pharmaceutical precautions No special storage precautions are required.

Diluents: Tragacanth Mucilage BPC or Syrup BP should be used as diluents if required.

Legal category P.

Package quantities Bottles of 100 ml and 1,000 ml.

Further information Nil.

Product licence number 0068/5030.

PULMADIL* INHALER

PULMADIL* AUTO

Presentation Pulmadil Inhaler is a pressurised aerosol or bronchodilator inhalation therapy. The vial contains a suspension of rimiterol hydrobromide 10 mg/ml in aerosol propellant and delivers to the patient 300 measured doses each containing 200 mcg rimiterol hydrobromide.

Pulmadil Auto is a breath-actuated, pressurised aerosol or bronchodilator inhalation therapy. The vial contains a suspension of rimiterol hydrobromide 10 mg/ml in aerosol propellant and delivers to the patient 300 measured doses each containing 200 mcg rimiterol hydrobromide.

Uses Pulmadil is indicated for the relief of bronchospasm in bronchial asthma and chronic bronchitis.

Rimiterol hydrobromide is a sympathomimetic agent which has a rapid and highly selective action on β_2 -adrenergic receptors in bronchial muscle. At therapeutic dose levels it has virtually no effect on β_1 -adrenergic receptors. Cardiac stimulation is therefore reduced to negligible levels and occurs only at high doses or in hypersensitive patients. The plasma half life of rimiterol in man is less than five minutes.

Dosage and administration One to three puffs should provide relief in most cases. This treatment dose should not be repeated in less than thirty minutes. No more than eight treatments should be taken in any 24-hour period.

Children: Pulmadil Inhaler and Pulmadil Auto should be administered to children only under the supervision of a responsible adult.

Instructions for use: Pulmadil Inhaler: With the dust cap removed, Pulmadil Inhaler should be shaken to disperse the particles of medicament in the propellant.

The mouthpiece should then be placed well into the mouth and the lips closed firmly around it. The patient should now breathe out fully through the adapter.

As soon as the patient starts to breathe in, the vial should be pressed firmly down into the adapter. This releases a dose. The adapter should now be taken from the mouth and the breath held for as long as possible to avoid exhalation of particles of medicament.

Before taking a further inhalation, the patient should

wait at least one minute to allow the full effect of the first to become apparent.

Pulmadil Auto: To obtain full benefit from Pulmadil Auto the patient should follow these simple steps:

1. Shake the unit with the mouthpiece cover closed. Then open the mouthpiece cover downwards.

2. Breathe out as much as possible, then close the lips tightly round the mouthpiece. Keep the teeth apart and the tongue flat (to allow the flow of medicament into the lungs).

3. Suck in air through the mouthpiece as rapidly and deeply as possible. When the unit operates a click will be heard. *Continue to breathe in after the click* until the lungs are full. Hold the breath for a few seconds. Then take the inhaler away from the mouth and breathe out slowly through pursed lips. If no click is heard, repeat step 3, making sure that the lips are well sealed round the mouthpiece.

4. *The unit must be reset before another dose can be taken*, by closing the mouthpiece cover upwards. It is important to keep the cover closed when it is not in use.

Contra-indications, warnings, etc *Side-effects:* No side-effects of any significance have been reported.

Contra-indications: There are no known contra-indications, but 'Pulmadil' should be administered with care to patients with thyrotoxicosis.

Overdosage: As rimiterol is rapidly eliminated from the blood it carries little risk of accumulation even if used excessively. No cases of overdosage have been reported and the following guidance is based on theoretical considerations.

Symptoms: The blood pressure may fall and cause dizziness and fainting. Anxiety, tremor and tachycardia may be present.

Treatment: General symptomatic therapy.

Excessive use in asthmatics: Excessive use of any bronchodilator aerosol can indicate lack of response. This is a grave sign suggestive of status asthmaticus. It is recommended that 100 mg of hydrocortisone be given intravenously immediately and the patient admitted to hospital without delay.

Pharmaceutical precautions Pulmadil Inhaler and Pulmadil Auto should be stored in a cool place, protected from frost and direct sunlight.

As the Pulmadil vial is pressurised, no attempt should be made to puncture or dispose of it by burning.

The shelf-life of both Pulmadil preparations is three years.

Legal category POM.

Package quantities Pulmadil Inhaler is supplied as a complete standard pack, comprising a vial delivering 300 doses and an adapter.

Pulmadil Auto is supplied as a complete unit for which replacement cartridges are available. Each cartridge deliver 300 doses.

Further information Nil.

Product licence number 0068/0030.

RAUWILOID*

Presentation Dark cream circular, bi-convex tablets, diameter 8 mm, marked 'RD' on one side and 'RIKER' on the other. Each tablet contains 2 mg alseroxylon fraction

(selected alkaloid hydrochlorides) of *Rauwolfia serpentina*.

Uses Rauwiloid is indicated for the treatment of mild to moderate hypertension.

When a more pronounced fall in blood pressure is needed, Rauwiloid can be combined with other anti-hypertensive agents, such as the thiazide diuretics. Rauwiloid reduces blood pressure by interfering with transmission at sympathetic nerve endings, and depleting the myocardium of its catecholamines (chiefly noradrenaline).

The antihypertensive activity of Rauwiloid is complemented by mild bradycardic and tranquillising effects.

Rauwiloid causes a slow but prolonged release of serotonin and catecholamines from stores in various parts of the body. This release leads eventually to the depletion of noradrenaline at the post-ganglionic nerve endings of the sympathetic nervous system, in the blood-vessel walls, and in other organs such as the heart and spleen. Depletion of noradrenaline results in a generalised reduction of sympathetic transmission. Since the sympathetic system is the pathway for vasoconstrictor impulses, vasomotor tone is reduced. This reduction is particularly noticeable in vascular areas such as the skin and splanchnic circulation, and the resulting peripheral vasodilatation produces a lowering of blood pressure.

Dosage and administration Initially, two tablets (4 mg) daily. This may be taken as a single dose at night or in divided doses. When the blood pressure is stable at the lower level a maintenance dose of one tablet daily may be sufficient.

Onset of antihypertensive effect is graded and may not be apparent for four weeks or more after the start of treatment.

Contra-indications, warnings, etc

Side-effects: Nasal stuffiness, drowsiness and a slight looseness of the bowel (although diarrhoea is rare) may occur. There might also be a slight increase in appetite and an increase in weight. As with other *Rauwolfia* preparations, the possibility of mental depression must be considered. However, serious mental depression has not been reported as a result of Rauwiloid therapy.

Contra-indications: There are no absolute contra-indications to the use of Rauwiloid. It should, however, be administered with caution to patients who have a history of depression or peptic ulcer.

Overdosage: Symptoms: Mild overdosage can produce nasal congestion, gastro-intestinal upsets such as vomiting and diarrhoea, drowsiness, apathy, fatigue, headache, vertigo, hallucinations.

Higher doses may cause flushing, insomnia, vasodilatation, bradycardia, severe depression, sodium retention, oedema, peptic ulceration.

After a single massive dose most of the above effects are not encountered. Instead, the patient becomes sleepy and eventually comatose. Coma may last for several days.

Treatment: In the acutely poisoned patient, who is not in a coma, an emetic should be administered, or gastric lavage performed, even several hours after ingestion of the alkaloid. A saline cathartic should be left in the stomach. Nasal congestion, excessive salivation, gastro-intestinal upsets and other parasympathetic side-effects may also be controlled by small doses of atropine.

Epigastric pain and peptic ulcer may be treated with local antacid therapy.

Unless the blood pressure becomes very low, vasopressor drugs which may prove inactive (e.g. ephedrine) or which may lead to exaggerated cardiovascular response (e.g. adrenaline or noradrenaline) should be avoided. Blankets and external application of mild heat should be used to maintain normal body temperature.

Pharmaceutical precautions No special storage precautions are required.

Legal category POM.

Package quantities Bottles of 60 and 500 tablets.

Further information Nil.

Product licence number 0068/5010.

RAUWILOID* + VERILOID*

Presentation Light reddish-brown, circular, biconvex tablets, 8.0 mm diameter, marked R/V on one side and 'RIKER' on the other. Each tablet contains Rauwiloid brand of alkaloid hydrochlorides of *Rauwolfia serpentina* 1 mg, and standardised alkaloids of *Veratrum viride* equivalent to 3 mg of 100% potency material.

Uses Rauwiloid + Veriloid is indicated for moderate to severe essential hypertension.

Rauwiloid reduces blood pressure by interfering with transmission at sympathetic nerve endings, depleting the myocardium of its catecholamines (chiefly noradrenaline).

Rauwiloid also has mild bradycardic and tranquillising effects.

Rauwiloid causes a slow but prolonged release of serotonin and catecholamines from stores in various parts of the body. This release leads eventually to depletion of noradrenaline at the post-ganglionic nerve endings of the sympathetic nervous system in the blood-vessel walls, and in other organs such as the heart and spleen. Depletion of noradrenaline results in a generalised reduction of sympathetic transmission. Since the sympathetic system is the pathway for vasoconstrictor impulses, vasomotor tone is reduced. This reduction is particularly noticeable in vascular areas such as the skin and splanchnic circulation, and the resulting peripheral vasodilatation produces a lowering of blood pressure.

Veriloid produces a complementary antihypertensive effect, accompanied by bradycardia. This is brought about by inhibition of the vasomotor centre and stimulation of the vagus. Veriloid does not affect ganglionic or adrenergic responses. Heart, kidney and liver functions are unimpaired.

Dosage and administration Initially, one tablet three times daily at minimum intervals of four hours and preferably after meals. After two weeks, this may be increased, if necessary, by stages to a maximum of eight tablets daily, although the average requirement of Rauwiloid + Veriloid is one tablet four times daily.

Contra-indications, warnings, etc

Side-effects: Postural hypotension, gastric disturbance or emesis may occur from higher doses.

Contra-indications: Rauwiloid + Veriloid is contra-indicated in patients receiving quinidine.

Because of the *Rauwolfia* constituent, Rauwiloid + Veriloid should be administered with caution to patients with a history of depression or peptic ulcer.

Overdosage: Overdosage with Rauwiloid + Veriloid is

RIKOSPRAY* SILICONE

Presentation White suspension in a pressurised
aerosol container. The application of Rikospray Silicone
delivered to the skin contains:

Aluminium dihydroxyallantoinate	0.5% w/w
Cetylpyridinium Chloride BP	0.02% w/w
Dimethicone 1,000 BP to	100%

Uses Rikospray Silicone is indicated in: the prevention
and treatment of bedsores, particularly in incontinent
patients; the prevention and treatment of napkin rash;
colostomy hygiene.

Rikospray Silicone delivers a spray which coats the
skin with a film of virtually 100% silicone. The silicone
compounds are well known for their water-repellent and
protective properties. The protective film is instantly
impervious to water, urine or faeces.

Aluminium dihydroxyallantoinate is an amphoteric
substance which is insoluble in water and alcohol. It
combines the astringent and bacteriostatic activity of
aluminium with the healing properties of allantoin, and
is also a mild antiperspirant. No irritant or sensitising
properties have been reported from its use.

Cetylpyridinium chloride possesses bactericidal
properties.

Administration *Directions for use:* Before applying
Rikospray Silicone, the affected area should be washed
thoroughly and the skin dried carefully.

The canister should be shaken before use, and then
held about six to nine inches from the skin. Rikospray
Silicone should be applied sparingly to cover the entire
area. This should be done twice daily for at least one
week, then application once daily will often be sufficient.

Contra-indications, warnings, etc

Side-effects: None reported.

Contra-indications: None.

Overdosage: Not applicable.

Pharmaceutical precautions The shelf life of Rikospray Silicone is five years.

As the Rikospray Silicone canister is pressurised, it should not be punctured, incinerated or exposed to heat, including the sun, even when empty.

Legal category GSL.

Package quantities Canisters of 200 g.

Further information Nil.

Product licence number 0068/5080.

THEODROX*

Presentation White to creamy-white, circular, bi-convex tablets, 12.0 mm diameter, marked TX on one side and 'RIKER' on the other. Each tablet contains Dried Aluminium Hydroxide Gel BP 260 mg and Aminophylline BP 195 mg.

Uses Theodrox is indicated in the prophylaxis of bronchospasm in asthma and chronic bronchitis.

Aminophylline is a combination of theophylline and ethylenediamine. It has properties very similar to those of theophylline but is more soluble. It relaxes involuntary muscle and relieves bronchial spasm. In common with other xanthine compounds, aminophylline has a diuretic action.

Administered orally, aminophylline can cause gastric irritation. However, in Theodrox this possibility is reduced by the simultaneous administration of aluminium hydroxide gel, which counteracts gastric acidity and retards the breakdown of aminophylline to theophylline in the stomach. By this means, larger doses of aminophylline can be given with less risk of side-effects such as nausea and vomiting.

Dosage and administration *Adults:* 1 tablet three times daily and one at night.

Theodrox is not recommended for children.

Contra-indications, warnings, etc

Side-effects: Occasionally, nausea or vomiting may occur in some patients.

Caution: Theodrox should be administered with caution to patients with peptic ulcer.

Overdosage: *Symptoms:* Nausea and vomiting.

Treatment: If necessary the stomach should be emptied by aspiration and lavage.

Pharmaceutical precautions No special storage precautions are required.

Legal category P.

Package quantities Bottles of 100 tablets.

Further information Nil.

Product licence number 0068/5011.

THIAVER*

Presentation Oval, pale blue tablets, with a break line on one side and 'RIKER' on the other. Each tablet contains standardised alkaloids of *Veratrum viride* equivalent to 4 mg of 100% potency material, and epithiazide 4 mg.

Uses Thiaver is an antihypertensive preparation, which is indicated in all grades of benign, essential hypertension.

The total antihypertensive effect of Thiaver results from the combined actions of the *Veratrum viride* alkaloids (which have a centrally mediated antihypertensive action) and epithiazide (which has a diuretic/antihypertensive effect).

The main pharmacological action of the *Veratrum viride* alkaloids is the antihypertensive effect accompanied by bradycardia. This is brought about by inhibition of the vasomotor centre and stimulation of the vagus. The *Veratrum viride* alkaloids do not affect ganglionic or adrenergic responses. Heart, kidney and liver functions are unimpaired.

Epithiazide is an antihypertensive thiazide diuretic with pharmacological properties broadly resembling those of the thiazides in general. Its use in Thiaver complements the antihypertensive action of the *Veratrum viride* alkaloids and is associated with negligible potassium loss.

Dosage and administration One tablet, two or three times daily.

Maximum response to treatment may not be achieved until after one or two weeks.

Thiaver is not recommended for children.

Contra-indications, warnings, etc

Side-effects: Mild gastro-intestinal disturbances, e.g. nausea, dizziness, headache, malaise, weakness and fatigue may occasionally occur.

Caution: Both epithiazide and the *Veratrum viride* alkaloids potentiate the action of other antihypertensive agents.

As a precautionary measure, patients with a tendency to hypokalaemia (e.g. patients with severe cardiac, renal or hepatic disease, or on corticosteroids or digitalis therapy) should receive regular electrolyte determinations.

Also, as diabetes mellitus and gout may occur with thiazide therapy, if either condition is suspected, blood glucose or blood uric acid determinations should be undertaken.

Overdosage: Overdosage with Thiaver is unlikely, because vomiting usually occurs.

Overdosage with *Veratrum viride* alkaloids: Symptoms include substernal and epigastric burning, severe nausea and vomiting, cold sweats, shallow respiration and vertigo.

Treatment: The stomach should be emptied by aspiration and lavage with warm water.

Excessive hypotension with bradycardia or cardiac arrhythmias may be treated by intramuscular injection of 500 mcg atropine sulphate.

The patient should be supine with the feet raised.

Pharmaceutical precautions The bottles are supplied with a charcoal sachet and this should not be removed.

Legal category POM.

Package quantities Bottles of 100 tablets.

Further information Nil.

Product licence number 0068/5068.

lar, bi-convex tablets, on one side and 'RIKER' and 'Calcium Carbonate' on the other. Each contains 100 mg of Neomycin Acid USNF (glycine).

the relief of hyperacidity, gastritis, and indigestion following administration of drugs. It acts as an antacid and prolongs the action of drugs.

sterile.

Indicated for the prevention and treatment of surgery, at any stage of

absorbed from broken or abraded skin. It should not be used on large areas of skin due to burns, sunburn, inflammatory dermatoses, or pruritis and minor skin

in, bacitracin and polymyxin B. It provides an almost complete barrier against the common pathogenic bacteria and infected skin. It is non-toxic and non-touch application; it is indicated during manufacture of spray which is evenly

Neomycin is a broad-spectrum antibiotic, primarily bactericidal rather than bacteriostatic. It is not inactivated by pus, exudates, gastro-intestinal secretions, bacterial growth products or enzymes. Hypersensitivity reactions are uncommon.

Bacitracin is effective against most Gram-positive organisms. However, it is not destroyed by Gram-negative bacteria and can be of value in the control of mixed infections.

Polymyxin B is selectively bactericidal to Gram-negative bacteria (particularly *Pseudomonas aeruginosa*, *Escherichia coli*, *Aerobacter aerogenes*, *Haemophilus influenzae*, Friedlander's bacillus and the dysentery group) but exerts no action on *Proteus*. Topical applications of polymyxin B have been found effective in the prophylaxis and treatment of infection in granulating surfaces.

Dosage and administration *Directions for use:* The canister should be shaken before and between applications, and held six to nine inches from the skin.

The spray should be applied sparingly to cover the affected area and should be kept clear of the eyes.

Important: During use, the canister should not be inverted or inclined at an angle greater than 45°.

Application of Tribiotic Spray should be limited in adults to a maximum of one canister per day for no more than seven days. Patients with renal impairment are particularly vulnerable to neomycin ototoxicity and the dose should be appropriately reduced.

Dosage should not exceed 15 mg neomycin/kg body weight/day in children. Each 1 second spray contains approximately 15 mg neomycin.

Greater caution should be exercised when treating infants.

Occasionally, blockage may occur from agglomeration of the powder in the outlet of the actuating button. This can easily be cleared with a sterile hypodermic needle (No. 15-17).

Use in pregnancy: Due to lack of sufficient information, the product should not be administered during the first trimester of pregnancy or during lactation unless the clinical need outweighs the possible risk.

Contra-indications, warnings, etc

Contra-indications: Because of the risk of systemic absorption Tribiotic Spray is not recommended for the treatment of burns. The only other contra-indication is allergic sensitivity to one or more of the constituents.

Precautions: The quantity of neomycin absorbed after topical administration is usually small. However, if high doses are applied, sufficient absorption can occur to cause permanent loss of hearing; the maximum recommended dose should not therefore be exceeded. Nephrotoxicity, resulting in ototoxicity may also occur. Care should be taken in patients with a hearing loss.

The concurrent use with other aminoglycoside antibiotics is not recommended and caution should be exercised in case of cross hypersensitivity to other aminoglycoside antibiotics.

The possibility of resistant organisms should be considered.

Neomycin has inherent neuromuscular blocking activity and may potentiate the action of similar agents, causing respiratory depression.

Overdosage: Overdosage only occurs with chronic use rather than acute.

Pharmaceutical precautions

Storage: Store in a cool place. The shelf-life of Tribiotic Spray is three years.

Container: As the Tribiotic Spray canister is pressurised, it should not be punctured, incinerated or exposed to heat, including the sun, even when empty.

Legal category POM.

Package quantities Canister of 110 g.

Product licence number 0068/5075.

VERILOID*

Presentation Veriloid contains standardised alkaloids of *Veratrum viride* equivalent to 2 mg of 100% potency material. The tablets are yellow, circular, bi-convex, 6.4 mm diameter, a break line on one side and 'RIKER' on the other.

Uses Veriloid is an oral antihypertensive preparation and is indicated in moderate to severe hypertension.

The main pharmacological action of the *Veratrum viride* alkaloids is the antihypertensive effect accompanied by bradycardia. This is brought about by inhibition of the vasomotor centre and stimulation of the vagus. Veriloid does not affect ganglionic or adrenergic responses. Heart, kidney and liver functions are unimpaired.

Dosage and administration 9–15 mg daily doses, at intervals of six to eight hours.

Veriloid is not recommended for children.

Contra-indications, warnings, etc

Side-effects: Postural hypotension, gastric distress or emesis may result from high doses of Veriloid.

Contra-indications: Veriloid is contra-indicated in patients receiving quinidine.

Overdosage: Serious overdosage with Veriloid because vomiting usually occurs before toxic effects are reached.

Symptoms include substernal and epigastric severe nausea and vomiting, cold sweats, shallow respiration and vertigo.

Treatment: The stomach should be emptied by vomiting and lavage with warm water.

Excessive hypotension with bradycardia and arrhythmias may be treated by intramuscular injection of 500 mcg atropine sulphate. The patient should be kept warm with the feet raised.

Pharmaceutical precautions No special precautions are required.

DIMOTANE* L.A.
DIMOTANE* TABLETS
DIMOTANE* ELIXIR

'resentation *Dimotane L.A.*: Sugar-coated, peach-coloured tablet monogrammed AHR in black. Each tablet contains Brompheniramine Maleate USP 12.0 mg (one-third of active ingredient in coating for immediate release; two-thirds of active ingredient in delayed-release core).

Dimotane Tablets: Scored, peach-coloured compressed tablet stamped AHR. Each tablet contains Brompheniramine Maleate USP 4.0 mg.

Dimotane Elixir: Cola-flavoured, pale yellow-green-coloured liquid. Each 5 ml contains Brompheniramine Maleate USP 2.0 mg.

Uses Antihistaminic in the treatment of allergic conditions and reactions such as hay fever and urticaria.

Dosage and administration *Oral*: Dimotane L.A:

Adults: 1 to 2 tablets night and morning.

Children: 6–12 years: 1 tablet at night on retiring, a further tablet may be taken in the morning if necessary.

Dimotane tablets:

Adults: 1 to 2 tablets three or four times daily.

Children: 6–12 years: $\frac{1}{2}$ to 1 tablet three or four times daily.

Dimotane Elixir:

Adults: 10 to 20 ml three or four times daily.

Children: 6–12 years: 5 to 10 ml three or four times daily.

3–6 years: 5 ml three or four times daily.

Under 3 years: 0.4–1 mg/kg per 24 hours in four divided doses or at the discretion of the physician.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to the active ingredients. Coma or pre-coma states. Known brain damage or epilepsy.

Precautions and warnings: Drowsiness may occur. Patients receiving Dimotane should not drive nor operate machinery unless it has been shown that their physical and mental capacity remains unaffected. May potentiate the effects of CNS depressants including alcohol. The effects of anti-cholinergic drugs may also be potentiated. May act as a cerebral stimulant in children and occasionally in adults. If this occurs, it is possible that insomnia, nervousness, hyperpyrexia and tremors may occur and, very rarely, epileptiform convulsions. Therefore children taking Dimotane should not be left unattended for long periods. This product should not be used during pregnancy unless considered essential by the physician.

Treatment of overdose: Gastric lavage together with appropriate supportive therapy dependent upon individual response to the various constituents of the preparation.

Pharmaceutical precautions Protect from light.

Legal category P.

DIMOTANE* EXPECTORANT

Presentation Raspberry-flavoured, pale pink-coloured liquid. Each 5 ml contains:

Guaiphenesin BPC	100.0 mg
Phenylephrine Hydrochloride BP	5.0 mg
Phenylpropanolamine Hydrochloride BP	5.0 mg
Brompheniramine Maleate USP	2.0 mg

Uses Treatment of cough to facilitate expectoration. Dimotane Expectorant has been formulated to combine the expectorant properties of guaiphenesin together with decongestants, and an antihistamine.

Dosage and administration Oral:

Adults: 5 to 10 ml three or four times daily.

Children: 6–12 years: 5 ml three or four times daily

3–6 years: 2.5 to 5 ml three or four times daily

Under 3 years: At the discretion of the physician.

Suggested dosage 1.0 to 2.5 ml three or four times daily.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to the active ingredients. Coma or pre-coma states. Known brain damage or epilepsy. Use in patients with acute ischaemic heart disease, thyrotoxicosis, glaucoma, or urinary retention. Patients currently receiving, or who have within two weeks received, monoamine oxidase inhibitors or tricyclic antidepressants. Patients receiving other sympathomimetic drugs.

Precautions and warnings: Drowsiness may occur. Patients receiving Dimotane Expectorant should not drive nor operate machinery unless it has been shown that their physical and mental capability remains unaffected. May potentiate the effects of CNS depressants including alcohol. The effects of anticholinergic drugs may also be potentiated. May act as a cerebral stimulant in children and occasionally in adults. If this occurs it is possible that insomnia, nervousness, hyperpyrexia or tremor may occur and, very rarely, epileptiform convulsions. Therefore children taking Dimotane Expectorant should not be left unattended for long periods. Should be used with caution in patients receiving digitalis, adrenergic blockers or anti-hypertensive agents. This product should not be used during pregnancy unless considered essential by the physician.

Treatment of overdose: Gastric lavage together with appropriate supportive therapy dependent upon individual response to the various constituents of the preparation.

Pharmaceutical precautions Avoid prolonged storage at low temperatures.

Legal category P.

Package quantities Bottles of 500 ml and 2 litres.

Further information Recommended diluent: Syrup BP.

Dimotane Expectorant contains: Ethanol (96%) BP 3.6% v/v.

This product contains 2500 mg sucrose per 5 ml.

Product licence number 0100/5007.

DIMOTANE* EXPECTORANT DC

Presentation Raspberry-flavoured, bright pink-coloured liquid. Each 5 ml contains:

Guaiphenesin BPC	100.0 mg
Phenylephrine Hydrochloride BP	5.0 mg
Phenylpropanolamine Hydrochloride BP	5.0 mg
Brompheniramine Maleate USP	2.0 mg
Hydrocodone Bitartrate USP	1.8 mg

Uses Treatment of severe cough. In Dimotane Expectorant DC the antitussive effect of hydrocodone bitartrate is included to control the harsh irritating cough, whilst the expectorant action of guaiphenesin together with decongestants aids the removal of bronchial debris. The antihistamine brompheniramine maleate controls any associated allergy.

Dosage and administration Oral:

Adults: 5 to 10 ml three or four times daily

Children – 6–12 years: 5 ml three or four times daily

3–6 years: 2.5 to 5 ml three or four times daily

1–3 years: At the discretion of the physician. Suggested dosage 1.0 to 2.5 ml three or four times daily.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to the active ingredients. Coma or pre-coma states. Known brain damage or epilepsy. Use in patients with acute ischaemic heart disease, thyrotoxicosis, glaucoma, or urinary retention. Patients currently receiving, or who have within two weeks received, monoamine oxidase inhibitors or tricyclic antidepressants. Patients receiving other sympathomimetic drugs.

Precautions and warnings: Drowsiness may occur. Patients receiving Dimotane Expectorant DC should not drive nor operate machinery unless it has been shown that their physical and mental capability remains unaffected. May potentiate the effects of CNS depressant including alcohol. The effects of anticholinergic drug may also be potentiated. May act as a cerebral stimulant in children and occasionally in adults. If this occurs it is possible that insomnia, nervousness, hyperpyrexia or tremor may occur and very rarely epileptiform convulsions. Therefore children taking Dimotane Expectorant DC should not be left unattended for long periods. Should be used with caution in patients receiving digitalis, adrenergic blockers or anti-hypertensive agents. Prolonged use of this product may induce dependence. This product should not be used during pregnancy unless considered essential by the physician.

Treatment of overdose: Gastric lavage together with appropriate supportive therapy dependent upon individual response to the various constituents of the preparation.

Pharmaceutical precautions Avoid prolonged storage at low temperatures.

Under 6 years: At the discretion of the physician.
motane with Codeine Paediatric is recommended.

motane with Codeine Paediatric:

ildren – 6–12 years: 5 to 10 ml four times daily

3–5 years: 5 ml four times daily

1–3 years: Dose at the discretion of the physician.
ggested dosage 2.5 to 5.0 ml four times daily.

Under 1 year: Not to be used.

ontra-indications, warnings, etc

ontra-indications: Hypersensitivity to the active ingre-
nts. Coma or pre-coma states. Known brain damage
epilepsy. Use in patients with acute ischaemic heart
ease, thyrotoxicosis, glaucoma, or urinary retention.
tients currently receiving, or who have within two
eks received, monoamine oxidase inhibitors or tri-
clic antidepressants. Patients receiving other sym-
thomimetic drugs.

ecautions and warnings: Codeine is a narcotic anal-
sic. Drowsiness may occur. Patients receiving Dimo-
ne with Codeine should not drive nor operate machin-
/ unless it has been shown that their physical and
ental capability remains unaffected. May potentiate
e effects of CNS depressants including alcohol. The
ects of anticholinergic drugs may also be potentiated.

May act as a cerebral stimulant in children and occa-
sionally in adults. If this occurs it is possible that
insomnia, nervousness, hyperpyrexia or tremor may
occur and very rarely epileptiform convulsions. Therefore
children taking Dimotane with Codeine should not be
left unattended for long periods. Should be used with
caution in patients receiving digitalis, adrenergic blockers
or anti-hypertensive agents. This product should not be
used during pregnancy unless considered essential by
the physician.

Treatment of overdosage: Gastric lavage together with
appropriate supportive therapy dependent upon individ-
ual response to the various constituents of the
preparation.

Pharmaceutical precautions Avoid prolonged stor-
age at low temperatures.

Legal category P.

Package quantities Bottles of 500 ml and 2 litres.

Further information *Recommended diluent:* Syrup
BP.

Dimotane with Codeine contains: Ethanol (96%) BP
3.6% v/v.

This product contains 825 mg sucrose and 1,000 mg
glucose per 5 ml.

Dimotane with Codeine Paediatric contains: Ethanol
(96%) BP 3.6% v/v.

This product contains 2,750 mg sucrose per 5 ml.

Product licence numbers

Dimotane with Codeine	0100/0042
Dimotane with Codeine Paediatric	0100/0046

DIMOTAPP* LA DIMOTAPP* ELIXIR DIMOTAPP* ELIXIR PAEDIATRIC

Presentation *Dimotapp LA:* Sugar-coated, choco-
late-coloured tablet monogrammed AHR in white. Each
tablet contains:

Brompheniramine Maleate USP	12.0 mg
Phenylephrine Hydrochloride BP	15.0 mg
Phenylpropanolamine Hydrochloride BP	15.0 mg

(one-third of active ingredients in coating for immediate
release; two-thirds of active ingredients in delayed-
release core).

Dimotapp Elixir: Grape-flavoured, pale red-brown col-
oured liquid. Each 5 ml contains:

Brompheniramine Maleate USP	4.0 mg
Phenylephrine Hydrochloride BP	5.0 mg
Phenylpropanolamine Hydrochloride BP	5.0 mg

Dimotapp Elixir Paediatric: Grape-flavoured, pale red-
brown coloured liquid. Each 5 ml contains:

Brompheniramine Maleate USP	1.0 mg
Phenylephrine Hydrochloride BP	2.5 mg
Phenylpropanolamine Hydrochloride BP	2.5 mg

Uses Anti-histaminic, nasal decongestant in the man-
agement of upper respiratory tract disorders, including
congestion, hypersecretion, rhinitis and sinusitis.

Dosage and administration *Oral:*

Dimotapp LA:

Adults: 1 to 2 tablets night and morning.

Dimotapp Elixir:

Adults: 5 to 10 ml three or four times daily

Children – 6–12 years: 5 ml three or four times daily
2–6 years: 2.5 ml to 5 ml three or four times daily.

Dimotapp Elixir Paediatric:

Children – 6–12 years: 10 ml three or four times daily
2–6 years: 2.5 to 10 ml three or four times daily

Under 2 years: At discretion of physician. Suggested dosage 2.5 ml three or four times daily.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to the active ingredients. Coma or pre-coma states. Known brain damage or epilepsy. Use in patients with acute ischaemic heart disease, thyrotoxicosis, glaucoma, or urinary retention. Patients currently receiving, or who have within two weeks received, monoamine oxidase inhibitors or tricyclic antidepressants. Patients receiving other sympathomimetic drugs. Dimotapp L.A. contains 3.0 mg of wheat flour per tablet and should be avoided by patients requiring a wheat-gluten-free diet (coeliac disease, dermatitis herpetiformis).

Precautions and warnings: Drowsiness may occur. Patients receiving Dimotapp should not drive nor operate machinery unless it has been shown that their physical and mental capability remains unaffected. May potentiate the effects of CNS depressants including alcohol. The effects of anticholinergic drugs may also be potentiated. May act as a cerebral stimulant in children and occasionally in adults. If this occurs it is possible that insomnia, nervousness, hyperpyrexia or tremor may occur and very rarely epileptiform convulsions. Therefore children taking Dimotapp should not be left unattended for long periods. Should be used with caution in patients receiving digitalis, adrenergic blockers or anti-hypertensive agents. This product should not be used during pregnancy unless considered essential by the physician.

Treatment of overdose: Gastric lavage together with appropriate supportive therapy dependent upon individual response to the various constituents of the preparation.

Pharmaceutical precautions Discolouration of tablets may occur when exposed to prolonged strong sunlight.

Legal category P.

Package quantities *Dimotapp L.A.*: Bottles of 100 and 500 tablets

Dimotapp Elixir: Bottles of 500 ml and 2 litres

Dimotapp Elixir Paediatric: Bottles of 500 ml

Further information Dimotapp Elixir and Dimotapp Elixir Paediatric contain Ethanol (96%) BP 2.5% v/v, Dimotapp L.A. contains sucrose 135 mg per tablet. The recommended diluent is Syrup BP.

Dimotapp offers the advantages of controlling the congestion and hypersecretion associated with sinusitis and rhinitis. The combination of phenylephrine hydrochloride and phenylpropanolamine hydrochloride in the formulations means that the problem of overdrying and rebound congestion is avoided, thus allowing the mucosa to return to its normal moist state.

DIMOTAPP* P ▼

Presentation A white, round, flat bevelled edge tablet embossed **AHR** containing:
 DPP

Brompheniramine Maleate USP	2.0 mg
Phenylephrine Hydrochloride BP	5.0 mg
Phenylpropanolamine Hydrochloride BP	5.0 mg
Paracetamol PhEur	325.0 mg

Uses Analgesic antihistaminic nasal decongestant the management of upper respiratory tract disorder such as sinusitis and rhinitis with associated pain.

Dosage and administration Oral:

Adults: 1 to 2 tablets three times daily.

Children: 6–12 years $\frac{1}{2}$ to 1 tablet three times daily

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to the active ingredients. Coma or pre-coma states. Known brain damage or epilepsy. Use in patients with acute ischaemic heart disease, thyrotoxicosis, glaucoma, or urinary retention. Patients currently receiving, or who have within two weeks received, monoamine oxidase inhibitors or tricyclic antidepressants. Patients receiving other sympathomimetic drugs.

Precautions and warnings: Drowsiness may occur. Patients receiving Dimotapp P should not drive nor operate machinery unless it has been shown that the physical and mental capability remains unaffected. May potentiate the effects of CNS depressants including alcohol. The effects of anticholinergic drugs may also be potentiated. May act as a cerebral stimulant in children and occasionally in adults. If this occurs it is possible that insomnia, nervousness, hyperpyrexia or tremor may occur and very rarely epileptiform convulsions. Therefore children taking Dimotapp P should not be left unattended for long periods. Should be used with caution in patients receiving digitalis, adrenergic blockers, or anti-hypertensive agents. This product should not be used during pregnancy unless considered essential by the physician.

Treatment of overdose: Gastric lavage together with appropriate supportive therapy dependent upon individual response to the various constituents of the preparation. Dimotapp P contains paracetamol. N-acetylcysteine I.V. or L-methionine orally should be administered as soon as possible following overdose.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Bottles of 100 and 500 tablets

Further information Dimotapp P offers the advantages of controlling the congestion and hypersecretion associated with sinusitis and rhinitis whilst at the same time controlling associated pain. The combination of phenylephrine hydrochloride and phenylpropanolamine hydrochloride in the formulation means that the problem of overdrying and rebound congestion is avoided, thus allowing the mucosa to return to its normal moist state.

Product licence number 0100/0057.

DOPRAM* INFUSION DOPRAM* INJECTION

Presentation *Dopram Infusion*: Clear colourless solution. Each 500 ml bottle contains:

oxapram Hydrochloride USP 2 mg per ml in 5%
Dextrose Injection BP.

opram Injection: Clear colourless solution. Each 5 ml
ampoule contains:

oxapram Hydrochloride USP 20 mg per ml

uses Respiratory stimulant.

acute respiratory failure: Dopram prevents and reverses
apnoea during administration of oxygen.

Following anaesthesia: Dopram reduces the incidence
of postoperative chest complications, and increases the
rate of recovery from inhalational anaesthesia. In addition
Dopram reduces respiratory depression associated with
analgesic therapy. Dopram aids the differential diagnosis
of postoperative apnoea.

dosage and administration For intravenous use
only. There is no recommended dosage schedule for
children.

For the treatment of respiratory failure: 0.5 mg per
minute to 4.0 mg per minute of Dopram Infusion
dependent upon the condition and response of the
patient. Whenever possible the condition of the patient
should be monitored by frequent measurement of blood
gas tensions.

Following anaesthesia: Usual dosage 1.0–1.5 mg/kg
body weight of Dopram Injection which may be repeated
at one hour intervals. Alternatively, Dopram Infusion
may be given at a rate of 2–3 mg per minute. Appropriate
adjustments to the administration rate should be made
according to the response of the patient.

opram Infusion: (a) Treatment of respiratory failure. To
prevent or reverse the depression of ventilation which
occurs in some hypoxic patients during oxygen
administration.

(b) Following anaesthesia. To stimulate ventilation in
the post operative period as an aid to the reduction of
post operative pulmonary complications.

To permit the use of effective doses of narcotic
analgesics without associated problems of respiratory
depression.

opram Injection: Following anaesthesia. To stimulate
ventilation in the post operative period as an aid to the
reduction of post operative pulmonary complications.

To permit the use of effective doses of narcotic
analgesics without associated problems of respiratory
depression.

To aid differential diagnosis and treatment of post
operative apnoea.

To increase the rate of recovery from anaesthesia
when this would be beneficial.

contra-indications, warnings, etc

contra-indications: Severe hypertension, status asth-
maticus, coronary artery disease, thyrotoxicosis.

precautions and warnings: Dopram should be adminis-
tered concurrently with oxygen to patients with severe
reversible airways obstruction or severely decreased
lung compliance, due to the increased work of breathing
in these patients. Although Dopram has been adminis-
tered safely to patients suffering from epilepsy, great care
should be employed when such patients are treated with
Dopram. Clinical data suggest that there may be
interaction between doxapram and aminophylline which
manifested by agitation and increased skeletal muscle
activity. Care should thus be taken when these two
drugs are used concomitantly. Dopram should also be
administered with great care to patients being treated

concurrently with monoamine oxidase inhibitors. Animal
studies have shown that the action of doxapram, in
common with a large number of drugs, is potentiated
after pre-treatment with a monoamine oxidase inhibitor.

In patients presenting with bronchoconstriction, Do-
pram should always be used in conjunction with
bronchodilator drugs in order to reduce the amount of
respiratory effort. Although studies in rats and rabbits
have not revealed any teratogenic effects of doxapram,
absolute safety in human pregnancy has not yet been
confirmed.

On recommended dosage a moderate increase in
blood pressure, a slight increase in heart rate, dizziness
and perineal warmth have been reported. Other side-
effects have been reported in the post anaesthetic period
but these are also commonly observed during recovery
from anaesthesia, and include muscle fasciculation,
hyperactivity, sweating, confusion, cough, dyspnoea,
laryngospasm, bronchospasm, sinus tachycardia, bra-
dycardia, extrasystoles, nausea and/or vomiting and
salivation.

Treatment of overdosage: Gross overdosage may result
in hypertension, tachycardia, and increased skeletal
muscle activity. The hypertension may be treated with
an appropriate α -adrenergic blocking agent and the
increase in skeletal muscle activity controlled with
intravenous barbiturates.

Pharmaceutical precautions Dopram is incompati-
ble with alkaline solutions such as aminophylline,
frusemide and thiopentone sodium. Store at room
temperature. Do not refrigerate Dopram Injection.

Legal category POM.

Package quantities

Dopram Infusion: Pack of 4 bottles each containing
500 ml

Dopram Injection: Pack of 5 ampoules each contain-
ing 5 ml

Further information The principal pharmacological
action of Dopram is an increase in minute volume
produced primarily by an increase in tidal volume and to
a lesser extent by changes in respiratory rate. Neuro-
pharmacological studies have shown that the primary
sites of action of Dopram are the peripheral chemore-
ceptors. It is considered that this site of action of Dopram
is responsible for its relative specificity of action: it is
only following large doses of Doxapram Hydrochloride
that non-specific central nervous system stimulation
occurs.

Dopram Injection: 0100/5018

FEAC* ▼

Presentation A two-layered biconvex tablet, film-
coated vermilion and monogrammed FEAC in white.
Each tablet contains:

Ascorbic Acid PhEur	150.0 mg
Nicotinamide PhEur	25.0 mg
Pyridoxine Hydrochloride PhEur	2.5 mg
Riboflavin PhEur	5.0 mg
Thiamine Mononitrate USP	7.5 mg

Dried Ferrous Sulphate BP 150.0 mg
(Equivalent to 45 mg elemental iron)

The vitamin constituents are contained in one layer in an immediate release form; the ferrous sulphate is contained in the controlled-release layer.

Uses For the treatment and prevention of iron deficiency anaemia accompanied by vitamin B and C deficiencies.

Dosage and administration *Oral:*

Adults: 1 tablet twice daily.

Contra-indications, warnings, etc

Contra-indications: There are no contra-indications.

Precautions and warnings: When FEAC is co-prescribed with levodopa, care should be exercised as the pyridoxine may antagonise the therapy. Iron chelates with tetracyclines and may impair absorption of both agents. Yellow colouration of urine is normal on recommended dosage. Nausea, gastrointestinal irritation and constipation may occasionally occur.

Treatment of overdosage: In the event of overdosage in adults (or children) 2 g desferrioxamine in water for injection should be given intra-muscularly and the stomach washed out with a 1% solution of sodium bicarbonate. 5 g desferrioxamine in 50–100 ml water should then be given by mouth or stomach tube preventing further absorption of iron.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Bottles of 100 tablets.

Further information Nil.

Product licence number 0100/0049.

RHEUMOX* 600 RHEUMOX* CAPSULES

Presentation *Rheumox 600 Tablets:* Pale orange, film-coated, capsule shaped tablets both sides scored with a breakline and one side printed RHEUMOX 600, containing Azapropazone Dihydrate 600 mg.

Rheumox Capsules: Two-tone orange size 1 capsule, monogrammed AHR Rheumox containing Azapropazone Dihydrate 300 mg.

Uses Rheumox is a non-steroidal anti-inflammatory analgesic agent indicated in the treatment of rheumatoid arthritis, ankylosing spondylitis, osteoarthritis and painful musculoskeletal conditions. Rheumox is also indicated in attacks of acute gouty arthritis and in the long term prophylaxis of gout and the control of hyperuricaemia.

Dosage and administration Rheumatoid arthritis, ankylosing spondylitis, osteoarthritis and painful musculoskeletal conditions.

Rheumox 600 Tablets: Oral – One 600 mg tablet night and morning.

Rheumox Capsules: Oral – One 300 mg capsule four times daily or two 300 mg capsules night and morning.

Older patients: Azapropazone is principally excreted unchanged by the kidney. In patients over 65 whose renal function may be reduced, it is therefore suggested that the starting dose be 300 mg in the morning and 600 mg to be taken last thing at night. In patients much

older than this, a suitable starting regimen is 600 mg night or 300 mg twice daily. This dosage can be subsequently adjusted since some elderly patients have excellent renal function.

Acute gout: 2,400 mg in divided doses during the first 24 hours followed by 1,800 mg per day until the attack is resolving after which 1,200 mg per day is used until symptoms have disappeared.

Chronic gout: Azapropazone reduces serum urate levels by enhancing urate excretion. The usual dosage for this purpose is 600 mg night and morning (either Rheumox 600 or Rheumox Capsules may be used). In patients over 65 the dosage should be 900 mg daily as described above and in some cases this may be reduced to 600 mg daily provided that adequate control of gouty symptoms and serum urate are maintained.

Paediatric dosage has not yet been established.

Contra-indications, warnings, etc

Contra-indications: Rheumox increases the plasma concentration of phenytoin and should not be given to patients taking this drug.

Rheumox potentiates the action of warfarin in many patients and should not be used with this or other oral anticoagulants. If it is essential that Rheumox be given to a patient already taking an oral anticoagulant, the dosage should not be done until the dose of the anticoagulant has been reduced to a very low level. Rheumox can then be introduced and the dose of the anticoagulant increased until the required effect is produced. Prothrombin determinations should be carried out daily throughout this procedure. Rheumox is not recommended in the presence of a peptic ulcer or where there is a history of blood dyscrasia. Patients on long term treatment should be regularly reviewed.

Precautions and warnings: Patients with a history of peptic ulcer have been treated safely with Rheumox but in this situation constant supervision is recommended. In some, ulceration may recur. Data at present available does not indicate that interaction occurs with drugs such as sulphonamides and oral hypoglycaemic agents but adjustments of the dosage of these drugs may be necessary in some instances.

Specific renal function tests in man and long term administration to animals have not revealed any adverse effects of Rheumox on the kidney but since its clearance is predominantly renal it is not recommended for use in patients with overt renal dysfunction. Animal reproduction studies did not result in foetal abnormalities but safety in human pregnancy cannot be assumed and its use should be avoided in pregnancy whenever possible.

Skin rashes occur occasionally and a proportion of these are photo-allergic reactions. Fluid retention and gastro-intestinal upsets also occur occasionally. Gastrointestinal bleeding has been reported as has angio-neurotic oedema.

Treatment of overdosage: If overdosage should occur two specific courses of action are suggested on theoretical grounds. Firstly, since Rheumox is poorly soluble in gastric juice, stomach lavage should recover any gastric residue of the drug, provided of course that it is done early enough.

Secondly, since Rheumox is predominantly excreted unchanged by the kidney, forced alkaline diuresis is theoretically indicated.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities *Rheumox 600 Tablets*: Amber glass bottles of 100 and 500 tablets.

heumox Capsules: Amber glass bottles of 100 and 500 capsules.

Further information Nil.

OBAXIN* 750

Presentation Scored white compressed capsule-shaped tablet embossed AHR containing:

methocarbamol USP 750 mg.

Uses Treatment of skeletal muscle spasm.

Dosage and administration *Oral*:

Adults: 2 tablets four times daily.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to methocarbamol. Coma or pre-coma states. Known brain damage or epilepsy. Use in presence of tachycardia, glaucoma, prostatic hypertrophy or bladder neck obstruction. Myasthenia gravis.

Precautions and warnings: This product may cause drowsiness and patients receiving it should not drive nor operate machinery unless their physical and mental capability remain unaffected – especially if other medication capable of causing drowsiness is also being taken. This product may potentiate the effects of other central nervous system depressants and stimulants including alcohol, barbiturates, anaesthetics and appetite suppressants.

The effects of anti-cholinergics, e.g. atropine and some psychotropic drugs may be potentiated by methocarbamol.

Robaxin may give rise to manifestations of allergy including skin rash, urticaria and angioneurotic oedema. This product may very rarely give rise to restlessness, anxiety, vertigo, tremor, confusion and convulsions. Lightheadedness and dizziness have been reported. Nausea and vomiting have also been reported during use of Robaxin.

In accordance with established medical practice this product should not be used during pregnancy unless considered essential by the physician.

Treatment of overdosage: Gastric lavage with appropriate supportive therapy for 24 hours as methocarbamol is excreted within that time.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Bottles of 100 tablets.

Further information Nil.

Product licence number 0100/5026.

OBAXIN* INJECTABLE

Presentation 10 ml sterile ampoules each containing:

methocarbamol USP 1.0 g

Vehicle 50% aqueous polyethylene glycol 300.

Uses Treatment of acute skeletal muscle spasm.

Dosage and administration 10–30 ml dependent on the severity of the condition and therapeutic response. Should not exceed 30 ml per day for more than three consecutive days, except in the treatment of tetanus.

Rate of administration:

Intravenous: Administer by slow intravenous injection or infusion directly into the vein at a maximum rate of 3 ml per minute.

Intramuscular: Not more than 5 ml into each gluteal region.

Diluent: May be added to an intravenous drip of sterile isotonic saline, or sterile 5% dextrose. Dilution should not be greater than 10 ml per 250 ml.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to methocarbamol. Coma or pre-coma states. Known brain damage or epilepsy. Use in presence of tachycardia, glaucoma, prostatic hypertrophy or bladder neck obstruction. Myasthenia gravis.

Precautions and warnings: This product may cause drowsiness and patients receiving it should not drive nor operate machinery unless their physical and mental capability remain unaffected – especially if other medication capable of causing drowsiness is also being taken. This product may potentiate the effects of other central nervous system depressants and stimulants including alcohol, barbiturates, anaesthetics and appetite suppressants. The effects of anti-cholinergics e.g. atropine and some psychotropic drugs may be potentiated by methocarbamol.

Robaxin may give rise to manifestations of allergy including skin rash, urticaria and angioneurotic oedema. This product may very rarely give rise to restlessness, anxiety, vertigo, tremor, confusion and convulsions. Lightheadedness and dizziness have been reported. Nausea and vomiting have also been reported during use of Robaxin.

Robaxin Injectable should be used with extreme caution in patients with impaired renal function, as the solvent used may cause raised urea levels and acidosis.

In accordance with established medical practice this product should not be used during pregnancy unless considered essential by the physician.

Treatment of overdosage: Appropriate supportive therapy for 24 hours as methocarbamol is excreted within that time.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Boxes containing 5 ampoules.

Further information Nil.

Product licence number 0100/5027.

ROBAXISAL* FORTE

Presentation A two-layer, pink and white compressed tablet scored and stamped AHR, containing:

Methocarbamol USP 400 mg

Acetylsalicylic Acid PhEur 325 mg

Uses In the management of pain and skeletal muscle spasm associated with musculoskeletal disorders such as lumbago, fibrositis, sprains, strains etc.

Dosage and administration *Oral:*

Adults: 2 tablets four times daily.

Safety in children 12 years of age and below has not been established.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to methocarbamol or aspirin. Coma or pre-coma states. Known brain damage or epilepsy. Use in presence of tachycardia, glaucoma, prostatic hypertrophy or bladder neck obstruction. Myasthenia gravis.

Precautions and warnings: This product may cause drowsiness and patients receiving it should not drive nor operate machinery unless their physical and mental capability remain unaffected – especially if other medication capable of causing drowsiness is also being taken. This product may potentiate the effects of other central nervous system depressants and stimulants including alcohol, barbiturates, anaesthetics and appetite suppressants. The effects of anti-cholinergics e.g. atropine and some psychotropic drugs may be potentiated by methocarbamol.

Robaxial Forte may give rise to manifestations of allergy including skin rash, urticaria and angioneurotic oedema. This product may very rarely give rise to restlessness, anxiety, vertigo, tremor, confusion and convulsions. Light-headedness and dizziness have been reported. Nausea and vomiting have also been reported during the use of Robaxial Forte. Patients currently on anti-coagulant therapy should have blood coagulation parameters regularly monitored.

In accordance with established medical practice this product should not be used during pregnancy unless considered essential by the physician.

Treatment of overdose: Supportive therapy for 24 hours, as methocarbamol is excreted within that time. If salicylate intoxication occurs, especially in children, the hyperpnoea may be controlled with sodium bicarbonate. Judicious use of 5% CO₂ with 95% O₂ may be of benefit. Abnormal electrolyte patterns should be corrected with appropriate fluid therapy.

Pharmaceutical precautions Nil.**Legal category** POM.

Package quantities Bottles of 100 and 500 tablets.

Further information Nil.

Product licence number 0100/5028.

ROBINUL*

Presentation Scored pink compressed tablet stamped AHR containing:

2
Glycopyrrolate USP 2.0 mg

Uses Treatment of peptic ulcer and gastro-intestinal hypermotility.

Dosage and administration *Oral:*

Adults: $\frac{1}{2}$ –2 tablets two or three times daily.

Contra-indications, warnings, etc

Contra-indications: Glaucoma and pyloric stenosis.

Precautions and warnings: Care is required when treating patients with known or suspected prostatic disease. Blurred vision, dry mouth, tachycardia, drowsiness and mild abdominal discomfort may occur. Patients receiving glycopyrrolate should not drive nor operate

machinery unless it has been shown not to affect the physical or mental ability. Do not use during pregnancy as safety in this condition has not been established. Reproduction studies in rats and rabbits revealed no teratogenic effects from glycopyrrolate. However, diminished rates of conception and of survival at weaning were observed in rats, in a dose related manner. Studies in dogs suggest that this may be due to diminished seminal secretion which is evident at high doses of glycopyrrolate. The significance of this for man is not clear.

Treatment of overdose: Gastric lavage or induced emesis is advised. Catheterisation may be necessary.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Bottles of 100 tablets.

Further information Nil.

Product licence number 0100/5029.

ROBINUL* INJECTION ▼

Presentation 3 ml and 1 ml ampoule (snap-open ampoule) of isotonic aqueous solution containing in each 1 ml:

Glycopyrrolate USP 0.2 mg

Uses *Properties:* Robinul (glycopyrrolate) is a quaternary ammonium anticholinergic agent. The quaternary ammonium moiety renders Robinul highly ionised at physiological pH and it thus penetrates the blood brain and placental barriers poorly. The effect of Robinul on secretory organs is particularly marked and prolonged, and good control of salivary and pharyngeal secretion can be obtained with doses which do not produce marked changes in heart rate. Gastric secretions are similarly, reduced by Robinul.

Indications: 1. To protect against the peripheral muscarinic actions of anticholinesterases such as neostigmine and pyridostigmine, used to reverse neuromuscular blockade produced by nondepolarising muscle relaxants.

2. As a preoperative antimuscarinic agent to reduce salivary, tracheobronchial and pharyngeal secretions and to reduce the acidity of the gastric contents.

3. As a preoperative or intra-operative antimuscarinic to attenuate or prevent intraoperative bradycardia associated with the use of suxamethonium or due to cardiac vagal reflexes.

Dosage and administration *Premedication – Adults* 0.2 mg to 0.4 mg intravenously or intramuscularly before the induction of anaesthesia. Alternatively, a dose of 0.004 to 0.005 mg/kg up to a maximum of 0.4 mg may be used. Larger doses may result in profound and prolonged antisialogogue effect which may be unpleasant for the patient.

Children: 0.004 to 0.008 mg/kg up to a maximum of 0.2 mg intravenously or intramuscularly before the induction of anaesthesia. Larger doses may result in profound and prolonged antisialogogue effect which may be unpleasant for the patient.

Intraoperative use – Adults: In those situations where intraoperative use is indicated, a single dose of 0.2 to 0.4 mg (or 0.004 to 0.005 mg/kg up to a maximum of 0.4 mg) by intravenous injection should be used. This dose may be repeated if necessary.

Children: In those situations where intraoperative use is indicated, a single dose of 0.004 to 0.008 mg/kg or up to a maximum of 0.2 mg by intravenous injection should be used. This dose may be repeated if necessary.

Reversal – Adults: 0.2 mg intravenously per 1 mg neostigmine or the equivalent dose of pyridostigmine. Alternatively, a dose of 0.01–0.015 mg/kg intravenously with 0.5 mg/kg neostigmine or equivalent dose of pyridostigmine. Robinul may be administered simultaneously on the same syringe with the anticholinesterase; greater cardiovascular stability results from this method of administration.

Children: 0.01 mg/kg intravenously with 0.05 mg/kg pyridostigmine or the equivalent dose of pyridostigmine. Robinul may be administered simultaneously on the same syringe with the anticholinesterase; greater cardiovascular stability results from this method of administration.

Contra-indications, warnings, etc

Contra-indications: Apart from established hypersensitivity to glycopyrrolate, there are no absolute contra-indications to Robinul.

Precautions and warnings: Reproduction studies in rats and rabbits revealed no teratogenic effects from glycopyrrolate. Safety in human pregnancy and lactation has not been established. However, diminished rates of conception and of survival at weaning were observed in rats, in a dose-related manner. Studies in dogs suggest that this may be due to diminished seminal secretion which is evident at high doses of glycopyrrolate. The significance of this for man is not clear.

Because of the increase in heart rate produced by the administration of anticholinergics, use with caution in patients with coronary artery disease; congestive heart failure; cardiac arrhythmias; hypertension; thyrotoxicosis. This product should be used very cautiously in pyrexial patients due to inhibition of sweating.

Large doses of quaternary ammonium anticholinergic compounds have been shown to block end plate nicotinic receptors. This should be considered before using glycopyrrolate in patients with myasthenia gravis.

It is known that the administration of anticholinergic agents during inhalation anaesthesia can result in ventricular arrhythmias.

Side-effects: Robinul may produce the following effects which are extensions of its fundamental pharmacological actions, dry mouth, difficulty in micturition, disturbances of visual accommodation, tachycardia, palpitation, inhibition of sweating.

Treatment of overdosage: Since glycopyrrolate is a quaternary ammonium agent symptoms of overdosage are peripheral rather than central in nature. To combat peripheral anticholinergic effects a quaternary ammonium anticholinesterase such as neostigmine methyl sulphate may be given in a dose of 1.0 mg for each 0.5 mg of glycopyrrolate known to have been administered by the parenteral route.

Pharmaceutical precautions Robinul Injection has been shown to be physically compatible with the following agents commonly used in anaesthetic practice: fluorophanol, Lorazepam, Droperidol and Fentanyl Citrate, Levorphanol Tartrate, Pethidine Hydrochloride, Morphine Sulphate, Neostigmine, Promethazine and Pyridostigmine.

Robinul Injection has been shown to be physically compatible with the following agents commonly used in anaesthetic practice:

Diazepam, Dimenhydrinate, Methohexitone Sodium, Pentazocine, Pentobarbitone Sodium, Thiopentone Sodium.

Robinul Injection should be stored at ambient temperature.

Legal category POM.

Package quantities Packs of 10 ampoules each containing 1 ml or 3 ml.

Further information Robinul Injection has been used successfully as an adjunct to reversal by neostigmine when atropine has been used as the preoperative anticholinergic.

The use of Robinul Injection as a preoperative anticholinergic is associated with less effect on the cardiovascular system, compared to atropine.

The use of Robinul Injection as an adjunct to reversal by neostigmine of non depolarising muscle relaxants is associated with less initial tachycardia and better protection against the cholinergic effects of neostigmine compared to reversal with a mixture of neostigmine and atropine.

Product licence number 0100/0054.

ROBINUL* POWDER

Presentation A white, crystalline powder Glycopyrrolate USP

Uses Iontophoretic treatment of the plantar and palmar skin for idiopathic hyperhidrosis.

Dosage and administration A 0.05% solution in distilled water of Glycopyrrolate USP is applied to palmar or plantar skin. When treating the foot or hand sufficient solution to cover the palm or sole is placed in a non-metallic container and the anode, of sheet metal larger in area than the part being treated, is placed in the solution. The sole or palm is separated from the anode by 5 mm of plastic foam or a layer of lint or sponge sheet.

In all cases an electrical circuit is completed by placing another limb in lukewarm tap water containing the cathode, similarly shielded from direct contact with the skin.

Recommended average conditions are 90 volts DC at 10–20 mA for adults and 2–10 mA for children, for 12 minutes at each site, depending on the patient's skin tolerance, body weight and size. Only one site should be treated at a time, and only two sites in any one day. Treatments should not be repeated within seven days, but may be repeated later varying the precise conditions according to the recurrence and severity of hyperhidrosis. See also Warnings section below.

Contra-indications, warnings, etc

Contra-indications: Glaucoma. Do not use during pregnancy.

Precautions and warnings: Glycopyrrolate may cause tachycardia. Since this drug may cause drowsiness, patients receiving glycopyrrolate should not drive nor operate machinery immediately after treatment unless it has been shown not to affect their physical or mental ability. It should be used with great caution in patients with cardiovascular disease, thyrotoxicosis and obstructive disorders of the lower urinary tract. Patients with mycotic or other skin infection should not be treated.

Dryness of mouth, blurred vision and mild abdominal discomfort may occur. Exercise care in patients with

prostatic hypertrophy. Due to the effect of anti-cholinergics on mucous secretions, it is advisable not to treat people with chronic bronchitis. Occasionally difficulty in eating may occur and micturition may be temporarily affected for some hours after treatment. A mild tingling feeling may occur in the immersed areas during treatment and any recent cuts or cracks in the skin may smart when the current is increased at the start of iontophoresis. The latter can be avoided by covering the lesion with a thin smear of petroleum jelly. Avoid over-exertion especially in hot weather, until any side effects have disappeared.

The product should only be used by specialist units experienced in iontophoretic technique.

The electrodes and treated skin areas *must* be placed in non-metallic containers and separated carefully by layers of, for example, sponge or lint. Direct contact between electrodes and skin must be avoided otherwise burns may result.

The current must be very slowly increased from zero mA and decreased to zero mA at the beginning and end of the treatment period respectively to avoid any Faradic discharge between the electrode and skin on removal of the patient's limb from the container of solution. Instruct patient that contact must not be broken during treatment.

Do not use during pregnancy as safety in this condition has not been established. Reproduction studies in rats and rabbits revealed no teratogenic effects from glycopyrrolate. However, diminished rates of conception and of survival at weaning were observed in rats, in a dose related manner. Studies in dogs suggest that this may be due to diminished seminal secretion which is evident at high doses of glycopyrrolate. The significance of this for man is not clear.

Pharmaceutical precautions Robinul Power is supplied in amber-glass bottles containing 5 grams. The powder is slightly hygroscopic and the container should not be left open. For use by iontophoresis the powder should be dissolved in freshly distilled or deionised water to the recommended concentration.

Prior to use a stock solution (e.g. 0.1% or 0.5% w/v) may be made up with freshly boiled and cooled distilled or deionised water. This stock solution should be stored in a refrigerator to minimise possible microbial growth and should be kept in thoroughly clean amber-glass, capped containers. Glycopyrrolate does hydrolyse very slowly at pH 7 and room temperature and it is recommended that stock solutions be kept for no more than 14 days. Do not keep solutions once used for iontophoretic treatment. The solution must not be alkaline, otherwise the glycopyrrolate will hydrolyse more rapidly.

Legal category POM.

Package quantities Supplied in amber-glass bottles containing 5 grams Glycopyrrolate USP.

Further information Further recommendations concerning treatment are given in the package insert.

Product licence number 0100/0052.

ROBITUSSIN*

Presentation Raspberry-flavoured, dark red-coloured liquid. Each 5 ml contains:

Guaiphenesin BP 100 mg

Uses Treatment of cough.

Dosage and administration *Oral:*

Adults: 5 to 10 ml every two to three hours.

Children: 3-12 years: 5 ml every two to three hours.

Under 3 years: 2.5 to 5 ml every two to three hours.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Avoid prolonged storage at low temperatures.

Legal category P.

Package quantities Bottles of 125 ml and 500 ml.

Further information *Recommended diluent:* Syru BP.

Robitussin contains Ethanol (96%) BP 3.6% v/v.

This product contains 2,500 mg sucrose per 5 ml.

Product licence number 0100/5031.

ROBITUSSIN* AC

Presentation Raspberry-flavoured, light amber-coloured liquid. Each 5 ml contains:

Guaiphenesin BP 100.0 mg

Pheniramine Maleate BP 7.5 mg

Codeine Phosphate PhEur 10.0 mg

Uses For the relief of cough especially when associated with allergy.

Dosage and administration *Oral:*

Adults: 5 to 10 ml four times daily.

Children - 6-12 years: 5 ml four times daily.

Under 6 years: At the discretion of the physician.

Contra-indications, warnings, etc

Contra-indications: Use in patients hypersensitive to the active ingredients. Coma or pre-coma states. Known brain damage or epilepsy.

Precautions and warnings: May cause drowsiness. Patients receiving Robitussin AC should not drive or operate machinery unless it has been shown that the physical and mental capability remains unaffected. May potentiate the effects of anti-cholinergic drugs and CNS depressants including alcohol. May act as a cerebral stimulant in children and occasionally in adults. If this occurs, it is possible that insomnia, nervousness, hyperpyrexia, and tremors may occur and very rarely epileptiform convulsions. In accordance with established medical practice this product should not be used during pregnancy unless considered essential by the physician.

Treatment of overdosage: Gastric lavage in the conscious patient together with supportive therapy where necessary. Further treatment is dependent on the individual response to the various constituents of the preparation.

Pharmaceutical precautions Avoid prolonged storage at low temperatures.

Legal category P.

Package quantities Bottles of 500 ml.

Further information *Recommended diluent:* Syru BP.

Robitussin AC contains Ethanol (96%) BP 3.6% v/v.

This product contains 2,500 mg sucrose per 5 ml.

Product licence number 0100/5032.

Hertfordshire AL7 3AY

ALCOBON®

Presentation Round, white tablets with 'ROCHE' printed on one face and a single break bar on the other, containing 500 mg flucytosine.

Infusion bottles containing 2.5 g flucytosine in 250 ml aqueous saline solution. The solution is colourless to slightly yellow. A sterile-packed giving-set is supplied in each bottle.

Properties: Alcobon is a fluorinated pyrimidine effective in the treatment of certain systemic fungal infections. In fungi sensitive to the preparation it acts as competitive inhibitor of uracil metabolism. In man it is excreted largely unchanged almost entirely in the urine. Flucytosine can be removed by haemodialysis.

Indications: Alcobon is indicated for the treatment of systemic infections with *Cryptococcus neoformans*, *Candida albicans* and certain other *Candida* species, *Orulopsis glabrata*, *Hansenula* and fungi which cause chromomycosis; *Phialophora verrucosa*, *Phialophora edrosi* and *Cladosporium carrionii*.

Alcobon for Infusion is indicated only when the patient is unable to accept oral Alcobon.

Dosage and administration For severe infections the total daily oral dose in adults and children is 200 mg/kg body weight divided into 4 doses. In patients harbouring extremely sensitive organisms a total daily dose of 100–150 mg/kg body weight may be sufficient.

Alcobon for Infusion should be administered using the giving-set provided, which contains a special filter. It may be administered directly into a vein, through a central venous catheter, or by intraperitoneal infusion. The recommended dosage is the same as for oral Alcobon, the total daily dose being divided over the 24 hours. Adequate effects can, however, often be obtained with a lower dose of Alcobon when the intravenous route is used.

It is suggested that the duration of the infusion should be of the order of 20 to 40 minutes provided this is balanced with the fluid requirements of the patient. As a rule, treatment with Alcobon for Infusion should rarely be required for periods of more than one week. The patient should be started on oral therapy with Alcobon tablets as soon as this becomes practicable.

Since Alcobon is excreted primarily by the kidneys, patients with renal impairment should be given smaller doses. The following is suggested as a guide for dosage in patients with severe infection associated with renal impairment:

in patients with creatinine clearance

<40 to >20 ml/min: 50 mg/kg every 12 hours.

<20 to >10 ml/min: 50 mg/kg every 24 hours.

<10 ml/min: an initial single dose of 50 mg/kg;

subsequent doses should be calculated according to the results of regular monitoring of the serum concentration of the drug, which should not be allowed to exceed

80 mcg/ml. Blood levels of 25–50 mcg/ml are normally effective.

The duration of treatment should be determined on an individual basis. The outcome of therapy will be affected by variations in the sensitivity of the infecting organism, its accessibility and its susceptibility to Alcobon, as well as by differences in the response of individual patients. In cases of cryptococcal meningitis, treatment should last for at least four months.

Alcobon Tablets are for oral administration.

Alcobon for Infusion is for intravenous or intraperitoneal administration.

Alcobon for Infusion may be given concurrently with other infusions of normal saline, dextrose or dextrose/saline. No other agent should be added to or mixed with Alcobon for Infusion.

Contra-indications, warnings, etc Precautions: Blood levels should be closely monitored in patients with renal insufficiency. If, for any reason, repeated measurements of the blood levels cannot be performed in cases of severe renal failure, Alcobon should not be given.

Because the levels of the drug in blood samples taken during or immediately after administration of Alcobon for Infusion are not a reliable guide to subsequent levels, it is advisable to remove blood for monitoring of blood levels of Alcobon shortly before starting the next infusion.

Special care should be taken in patients with blood dyscrasias and those in whom the bone marrow may be depressed because of disease or treatment. Regular blood counts and tests of liver function should be performed in all patients.

In calculating the fluid and electrolyte intake of patients with impaired renal function, cardiac failure or electrolyte imbalance, due allowance should be made for the volume and chloride content (138 millimole/litre) of Alcobon for Infusion.

Teratogenic effects have been seen in rats, in which species flucytosine is metabolised to fluorouracil. The metabolism may differ in man; nevertheless, the use of Alcobon in pregnancy and in women of childbearing age requires that the potential benefits of therapy be weighed against its possible hazards.

Side-effects: At the recommended doses, Alcobon is well tolerated. Nausea, vomiting, diarrhoea and skin rashes have occurred but are usually of a transient nature. Thrombocytopenia and leucopenia have been reported, mostly in those with serious underlying disease and receiving other medicaments. Changes in tests of liver function have been reported in about 10% of patients. Local irritation or phlebitis does not appear to be a problem with Alcobon for Infusion.

Treatment of overdosage: In the event of overdosage with Alcobon, it is recommended that gastric lavage should be performed and measures taken to encourage diuresis. Haemodialysis produces a rapid fall in the serum concentration of Alcobon.

Pharmaceutical precautions *Storage:* Alcobon Tablets should be stored in a well-closed container, protected against moisture.

Alcobon for Infusion should be stored between 15 and 20°C. If stored below 15°C, precipitation of Alcobon substance may occur, which should be redissolved by heating to 80°C for not more than 30 minutes. Prolonged storage above 20°C could lead to the decomposition of Alcobon resulting in the formation of 5-fluorouracil.

Additives: Alcobon for Infusion may be given concurrently with other infusions of normal saline, dextrose or dextrose/saline. No other agent should be added to or mixed with Alcobon for Infusion.

Legal category POM.

Package quantities Alcobon Tablets are available in packings of 100.

Alcobon for Infusion 2.5 g in 250 ml in packings of 5.

Further information *Availability:* Alcobon Tablets and Alcobon for Infusion are available to hospitals only.

Sensitivity testing: It is recommended that cultures for sensitivity testing be taken before treatment and repeated at regular intervals during therapy. However, it is not necessary to delay treatment until results of these tests are known. To determine sensitivities, the methods of Shadomy (*Appl. Microbiol.* 1969, **17**, 871) and Scholer (*Mykosen*, 1970, **13**, 179) are recommended.

For sensitivity testing it is essential that culture media are free of antagonists to flucytosine.

Tablets 0031/0069

Infusion 0031/0094

ALLOFERIN®

Presentation Ampoules containing 10 mg alcuronium chloride in 2 ml. The ampoule solution is almost colourless to pale yellow.

Uses *Properties:* Alloferin is a medium-acting neuromuscular blocking agent. It is a derivative of toxiferine, an alkaloid of calabash curare producing muscle relaxation of the non-depolarizing type.

Indications: Muscle relaxation: Alloferin is used for surgical and anaesthetic procedures in which a muscle relaxant is required.

Dosage and administration Response to Alloferin, as to other non-depolarizing relaxants, is subject to individual variation; underlying disease conditions or concurrently administered agents may significantly alter dosage requirements (see Precautions). The following doses are intended as a guide.

Adults: An initial dose of 0.20 to 0.25 mg/kg body-weight intravenously is usually adequate to achieve 95 per cent neuromuscular block. If endotracheal intubation is to be performed after administration of Alloferin, adequate laryngeal relaxation may be expected after a pause of 90–120 seconds. Profound muscle relaxation will continue for approximately 20–30 minutes when non-potentiating anaesthetic agents are employed. With an initial dose of 0.3 mg/kg body-weight, which may be used when intubating before longer procedures, muscle relaxation is obtained for approximately 40 minutes.

Incremental doses of one-sixth to one-quarter of the initial dose should provide relaxation for additional periods of similar duration to the first.

The following table is given as a more detailed guide to doses for a 70 kg patient

Anaesthetic	Intubation with Alloferin (mg)	Intubation with suxamethonium		
		Abdominal (mg)	Pelvic floor (mg)	Upper abd- men and thorax (mg)
N ₂ /O ₂	14–17.5	9	7	11
Halothane 1.5 to 2 vol. %	8.5–11	6	4.5	6.5

Children: There is insufficient information to recommend a dosage for Alloferin in neonates (up to 28 days of age). Older infants and children should be given 0.125–0.20 mg/kg body-weight.

Alloferin ampoules are for intravenous injection.

Alloferin ampoule solution may be diluted with Water for Injection immediately before use.

Maintenance of stability cannot be guaranteed when Alloferin ampoule solution is diluted.

Contra-indications, warnings, etc

Contra-indications: Alloferin is contra-indicated in patients with a history of hypersensitivity to the agent. Use of muscle relaxants is preferably avoided in patients with myasthenia gravis or myasthenic (Eaton-Lambert) syndrome.

Precautions: Like other neuromuscular blocking agents, Alloferin should only be administered in the presence of an experienced anaesthetist. The patient's ventilation should be controlled.

Alloferin is mainly excreted in the urine and may therefore accumulate in patients with renal impairment when repeated doses are given. Dosage should be reduced accordingly.

Alloferin is partly bound to serum albumin. Dosage requirements may therefore be altered in patients with hepatic or other disease in which serum protein levels are disturbed.

Increased sensitivity to non-depolarizing drugs may be seen in most neuromuscular diseases, especially amyotrophic lateral sclerosis, poliomyelitis, Duchenne muscular dystrophy and multiple neurofibromatosis.

Sensitivity to non-depolarizing relaxants may be increased by the following drugs: Antibiotics of the polymyxin and aminoglycoside groups (streptomycin, neomycin, kanamycin, gentamicin, amikacin, tobramycin), lincomycin; volatile anaesthetics (ether, halothane, methoxyflurane, cyclopropane, isoflurane, enflurane); drugs with local anaesthetic properties (including quinine, beta-blocking drugs, phenytoin, penicillamine); ganglion-blocking agents (e.g. trimetaphan).

In high concentrations, Mg may increase, whilst K, Na and Ca decrease non-depolarizing neuromuscular block. The action of Alloferin is reportedly not significantly altered by changes in blood pH within the physiological range. Where marked electrolyte or acid-base disturbances are present these should be corrected, if possible, before Alloferin is administered. Care should be taken with dosage especially in acidosis.

During hypothermia non-depolarizing neuromuscular blockade may be decreased. However, care is required during subsequent re-warming to ensure that increased effect does not lead to recurrence of paralysis.

No information is available on the effects of Alloferin on the developing foetus and its use in pregnancy should

arefore be avoided. Studies indicate that Alloferin does not cross the placenta in amounts that would affect the fetus at or near term.

de-effects: At doses producing adequate neuromuscular block Alloferin does not have marked ganglion-blocking, histamine-releasing or vagolytic actions. Nevertheless, its administration is usually followed by a transient (2–5 minute) lowering of blood pressure due to a fall in peripheral vascular resistance. Less regularly, there may be a moderate increase in heart rate; cardiac output is not significantly altered. Intraocular pressure remains stable.

A few cases of anaphylactoid reaction have been recorded following administration of Alloferin, in most instances in patients who have had previous anaesthesia or history of allergy.

Effects of overdosage and their treatment: Prolonged respiratory and muscular paralysis are symptoms of overdosage. Artificial ventilation must be continued, and the patient kept under observation until neuromuscular function is restored and there is no risk of recurrence of paralysis.

Prostigmin (neostigmine methylsulphate), given in a dose of 1 to 5 mg (0.08 mg/kg in children) with atropine 4 to 1.25 mg (0.02 mg/kg in children) by intravenous injection, is routinely used to speed reversal of the neuromuscular block.

Pharmaceutical precautions *Storage:* The recommended maximum storage temperature for Alloferin ampoules is 25°C; the Ampoules should be protected from light.

Alloferin should not be administered in the same syringe as thiopentone.

Legal category POM.

Package quantities Alloferin ampoules in packings of 10.

Further information Nil.

Product licence number 0031/5000.

ARFONAD*

Presentation Ampoules containing 250 mg trimethoprim camsylate in 5 ml. The ampoule solution is colourless.

Uses *Properties:* Arfonad is a ganglion-blocking agent which also has a direct dilator effect on peripheral vessels. It has a rapid, short and readily reversible action, which permits minute-to-minute control of the blood pressure.

Indications: Arfonad is used for surgical procedures if a hypotensive technique is clearly indicated. These may include: neurosurgery; vascular surgery; prostatectomy; chest surgery; thyroidectomy; bone and joint surgery.

Dosage and administration *Adults and children:*

1. Dilution to 250 ml with normal saline or glucose saline gives a 0.1% solution (1 mg per ml) which is the strength usually used for an intravenous drip. The Arfonad drip is started at an average of 60 drops approximately 3–4 mg) per minute and, having ascertained the patient's response, the rate of administration is then adjusted to maintain the desired level of

hypotension. Since there is marked variation in individual response, frequent blood pressure determinations are essential to maintain proper control.

2. If a weaker solution is preferred, a 0.05% solution can be prepared by diluting the 5% ampoule solution to 500 ml.

3. It is sometimes advisable to use a more concentrated solution in operations in which intravenous fluid should be restricted. For such patients a solution containing 0.25% Arfonad should be prepared by diluting the original 5% solution to 100 ml with normal saline or dextrose saline. The rate at which the drip is given should be correspondingly reduced.

4. The undiluted solution has also been used by intermittent intravenous injection.

As with other hypotensive drugs, Arfonad should be stopped before wound closure to allow the blood pressure to rise.

Arfonad Ampoules are for administration by intravenous drip and intermittent intravenous injection. Arfonad Ampoule solution may be diluted with Water for Injection, normal saline or dextrose saline immediately before use.

Contra-indications, warnings, etc

Contra-indications: Arfonad should not be used for hypotensive surgery in patients with severe arteriosclerosis or severe cardiac disease.

Effects of overdosage and their treatment: The major effect will be a marked fall in blood pressure below the desired level of hypotension. Tachycardia and respiratory depression may result, particularly if Arfonad is used concomitantly with a muscle relaxant. Vasopressor agents such as phenylephrine, ephedrine or noradrenaline are antidotes and may be used to effect a rapid return to normotensive level.

Pharmaceutical precautions *Storage:* Recommended maximum storage temperature 6°C; avoid freezing.

Additives: It is inadvisable to use the Arfonad drip as a vehicle for administering other drugs. Arfonad is known to be incompatible with thiopentone, gallamine triethiodide, strongly alkaline solutions, iodides and bromides.

Legal category POM.

Package quantities Arfonad Ampoules in packings of 10.

Further information Since the effect of Arfonad is neutralised by vasopressor drugs such as adrenaline, noradrenaline and ephedrine, local adrenaline infiltration at the site of incision is contra-indicated.

Product licence number 0031/5001.

BACTRIM* ROCHE

Approved name: Co-trimoxazole.

Presentation Bactrim tablets: round, pale yellow tablets with 'ROCHE' in a hexagon imprinted on one face, a single break bar on the other, containing 80 mg trimethoprim and 400 mg sulphamethoxazole.

Bactrim Drapsules*: capsuliform, orange, film-coated tablets with 'ROCHE' imprinted on one side, containing 80 mg trimethoprim and 400 mg sulphamethoxazole.

Bactrim Double Strength Tablets: oval, biconvex, white tablets with 'ROCHE' imprinted on one face, a 800 + 160

single break bar on the other, containing 160 mg trimethoprim and 800 mg sulphamethoxazole.

Bactrim Paediatric Tablets; round, white tablets with 'ROCHE' imprinted on one face, containing 20 mg trimethoprim and 100 mg sulphamethoxazole.

Bactrim Suspension (adult); pale yellow, aniseed-flavoured suspension containing 80 mg trimethoprim and 400 mg sulphamethoxazole in 5 ml.

Bactrim Paediatric Syrup; pink, aniseed-flavoured suspension containing 40 mg trimethoprim and 200 mg sulphamethoxazole in 5 ml.

Uses Properties: Bactrim is bactericidal *in vitro* to a wide range of Gram-positive and Gram-negative organisms, including *Streptococcus*, *Staphylococcus*, *Pneumococcus*, *Neisseria*, *Escherichia coli*, *Klebsiella*, *Proteus* spp., *Haemophilus*, *Salmonella*, *Shigella*, *Vibrio cholerae*, *Brucella*, *Pneumocystis carinii*, *Nocardia* and *Bordetella*. A particularly high degree of activity is exhibited against *Haemophilus influenzae*, *E. coli* and *Proteus* spp., making Bactrim particularly suitable for the treatment of chronic bronchitis and urinary tract infections.

Bactrim exerts its bactericidal action by the sequential blockade of two bacterial enzyme systems in the same metabolic pathway. The synergy thus produced accounts for the high degree of bactericidal activity.

Indications: Respiratory infections, including acute and chronic bronchitis (treatment and prophylaxis), also bronchiectasis, lung abscess, lobar and broncho-pneumonia, *Pneumocystis carinii* pneumonitis, sinusitis and otitis media. Urinary tract infections, including urethritis, cystitis, pyelitis, pyelonephritis and prostatitis. Gastro-intestinal tract infections caused by *Salmonella typhi* and *paratyphi*, including the chronic carrier state; bacillary dysentery and cholera (as an adjuvant to fluid and electrolyte replacement). Skin infections, including pyoderma, abscesses and wound infections. Septicaemias. Gonorrhoea. Other infections caused by a wide range of pathogenic bacteria, including acute and chronic osteomyelitis, acute brucellosis, nocardiosis and actinomycetoma, and in South American blastomycosis.

Dosage and administration Adults and children over 12 years: *Bactrim Tablets (adult) and Double Strength Tablets.* Usual dosage 2 Tablets (adult) or 1 Double Strength Tablet twice daily. Minimum dosage and dosage for long-term treatment (more than 14 days), 1 Tablet (adult) or $\frac{1}{2}$ Double Strength Tablet twice daily. For severe infections and septicaemias, 3 Tablets (adult) or $\frac{1}{2}$ Double Strength Tablets twice daily. For uncomplicated gonorrhoea, 4 doses of 4 Tablets (adult) or 2 Double Strength Tablets at 12-hourly intervals over two days may be given. Alternatively 2 doses of 5 Tablets (adult) or $2\frac{1}{2}$ Double Strength Tablets at an interval of up to 12 hours but not less than eight hours. (The same number of Drapsules* instead of Tablets (adult) may be given.) Bactrim Adult Suspension 5 ml = 1 Tablet (adult) or Drapsule.*

Bactrim Tablets (adult) may be dispersed in water or swallowed whole.

Children under 12 years: *Bactrim Tablets (adult).*

6–12 years: 1 tablet twice daily.

Bactrim Paediatric Tablets:

2–5 years: 2 paediatric tablets twice daily.

6–12 years: 4 paediatric tablets twice daily.

Bactrim Paediatric Syrup

6 weeks to 5 months: 2.5 ml twice daily.

6 months to 5 years: 5 ml twice daily.

6–12 years: 10 ml twice daily.

In children, this corresponds to an approximate dose 6 mg trimethoprim/kg body weight/day plus 30 n sulphamethoxazole/kg body weight/day, divided into equal doses.

The dosage required for the treatment of *Pneumocystis carinii* pneumonitis is generally higher than that recommended for other conditions. In children a dosage 20 mg trimethoprim/kg body weight/day, plus 100 n sulphamethoxazole/kg body weight/day, given equally divided doses every six hours for 14 days suggested. For this reason, treatment should be undertaken only if facilities for regular monitoring of blood levels of the sulphamethoxazole component are available.

Duration of therapy: In acute infections Bactrim should be given for at least five days or until the patient has been symptom-free for two days. Treatment for prostatitis and acute brucellosis should be maintained for a period of at least four weeks, whilst nocardiosis, actinomycetoma and South American blastomycosis require long term therapy.

All dosage forms are for oral administration.

Bactrim Adult Suspension and Bactrim Paediatric Syrup may be diluted with Syrup BP. Maintenance of stability cannot be guaranteed when Bactrim preparations are diluted.

Contra-indications, warnings, etc

Contra-indications: Bactrim is contra-indicated in patients showing marked liver parenchymal damage (blood dyscrasias, and in severe renal insufficiency where repeated measurements of the plasma concentration cannot be performed. Bactrim should not be given to patients with a history of sensitivity to sulphonamides (trimethoprim). Treatment must be immediately discontinued on the appearance of a skin rash.

Bactrim should not be given to premature babies nor during the first few weeks of life.

The drug should not be given during pregnancy. The usual caution in prescribing any drug for women of childbearing age should also be exercised with Bactrim.

Precautions: An adequate urinary output should be maintained. In cases with renal impairment a reduced or more widely spaced dosage is indicated to avoid accumulation of the drug. In such patients, measurement of the plasma concentration of the drug is advisable. Regular blood counts are necessary whenever long-term therapy is used. Special caution should be exercised in treating patients with conditions predisposing to folate deficiency.

Care should be taken when giving Bactrim to patients receiving sulphonylurea hypoglycaemic agents or coumarin anticoagulants as the action of these drugs may be increased.

Both trimethoprim and sulphamethoxazole are excreted in breast milk, but this does not contra-indicate the use of Bactrim in lactating mothers.

Side-effects: At the recommended dosage Bactrim is well tolerated. Nausea, vomiting, glossitis and skin rashes, including, rarely, erythema multiforme (Stevens-Johnson syndrome), can occur.

As Bactrim contains a sulphonamide, the possibility of blood dyscrasias like those associated with sulphonamides should be borne in mind. The changes reported with

actrim mainly consist of thrombocytopenia, purpura, leucopenia, neutropenia and, very rarely, agranulocytosis. They have usually proved to be reversible on withdrawal of the drug. Elderly patients are more susceptible to these blood changes. During long-term therapy, isolated cases of megaloblastic changes in the bone marrow have been reported; these are reversible by folic acid therapy.

Effects of overdosage and their treatment: Symptoms of overdosage may include vomiting, mental and visual disturbances, petechiae, purpura and jaundice. Haematuria, crystalluria and anuria may occur in severe cases.

Treatment is symptomatic and may include gastric lavage and forced diuresis. Alkalinisation of the urine may aid the elimination of the sulphamethoxazole component of Bactrim.

Hypersensitivity reactions may require treatment with steroids. Calcium folinate, 3 to 6 mg intramuscularly for 7 to 10 days, may be given to counteract the effects of trimethoprim on haemopoiesis.

Pharmaceutical precautions *Storage:* The recommended maximum storage temperature for Bactrim Adult Suspension and Paediatric Syrup is 30°C. No special precautions are required for other oral presentations of actrim.

Legal category POM.

Package quantities Bactrim Tablets (adult) in packings of 100 and 500.

Bactrim Drapsules in packings of 100 and 500.

Bactrim Double Strength Tablets in packings of 50.

Bactrim Paediatric Tablets in packings of 100.

Bactrim Adult Suspension in bottles of 100 ml.

Bactrim Paediatric Syrup in bottles of 100 ml.

Further information Bactrim IM Injection and, to hospitals only, Bactrim for Infusion are also available for patients in whom parenteral administration is indicated. See separate data sheets.

IACTRIM® ROCHE IM INJECTION

Improved name: Co-trimoxazole

Presentation Each 3 ml ampoule contains 160 mg trimethoprim and 800 mg sulphamethoxazole in a vehicle containing 52% glycofurol. The pH of the solution, which is faintly yellow, is approximately 9–10.

Uses *Properties:* Bactrim is bactericidal *in vitro* to a wide range of Gram-positive and Gram-negative organisms, including *Streptococcus*, *Staphylococcus*, *Pneumococcus*, *Neisseria*, *Escherichia coli*, *Klebsiella*, *Proteus* spp., *Haemophilus*, *Salmonella*, *Shigella*, *Vibrio cholerae*, *Brucella*, *Pneumocystis carinii*, *Nocardia* and *Tordetella*. A particularly high degree of activity is exhibited against *Haemophilus influenzae*, *E. coli* and *Proteus* spp., making Bactrim particularly suitable for the treatment of chronic bronchitis and urinary tract infections.

Bactrim exerts its bactericidal action by the sequential

blockade of two bacterial enzyme systems in the same metabolic pathway. The synergy thus produced accounts for the high degree of bactericidal activity.

Indications: Clinical experience with oral Bactrim indicates its therapeutic value in the following conditions:

Respiratory tract infections.

Renal and urinary tract infections.

Genital tract infections.

Gastro-intestinal tract infections caused by *Salmonella typhi* and *paratyphi*; bacillary dysentery and cholera (as an adjuvant to fluid and electrolyte replacement).

Skin and wound infections.

Septicaemias, osteomyelitis, acute brucellosis, nocardiosis and other infections caused by sensitive organisms.

Bactrim IM Injection is for use when intramuscular administration is preferable to oral therapy.

Dosage and administration Bactrim IM Injection is suitable only for intramuscular administration as described below. It is *not* suitable for any other route or method of administration.

Adults and children over 12 years: One 3 ml ampoule twice daily.

Maximum dosage (for severe infections): One and a half ampoules (4.5 ml) twice daily or one 3 ml ampoule three times daily.

Children 6–12 years: The recommended dosage is approximately 6 mg trimethoprim/kg body weight/day plus 30 mg sulphamethoxazole/kg body weight/day divided into two equal doses. As a guide, half an ampoule (1.5 ml) twice daily may be used. The dosage required for the treatment of *Pneumocystis carinii* pneumonitis is generally higher than that recommended for other conditions.

Bactrim IM Injection should not be given to children under the age of six years because of their small muscle mass.

Duration of treatment: it is recommended that Bactrim IM Injection should not be administered in the standard dosage (as indicated above) for more than five successive days, or in the maximum dosage for more than three successive days.

Mode of administration of Bactrim IM: Bactrim IM Injection should be given by deep intramuscular injection into the upper and outer quadrant of the buttock. Successive injections should be given alternately on opposite sides.

Any unused ampoule solution should be discarded.

The ampoule solution of Bactrim IM Injection should not be diluted.

Contra-indications, warnings, etc

Contra-indications: Bactrim is contra-indicated in patients showing marked liver parenchymal damage or blood dyscrasias and in severe renal insufficiency where repeated measurements of the plasma concentration cannot be performed. Bactrim should not be given to patients with a history of sensitivity to sulphonamides or trimethoprim. Treatment must be immediately discontinued on the appearance of a skin rash.

Bactrim should not be given to premature babies nor during the first few weeks of life.

The drug should not be given during pregnancy. The usual caution in prescribing any drug for women of childbearing age should also be exercised with Bactrim.

Precautions: An adequate urinary output should be maintained. In cases with renal impairment a reduced or more widely spaced dosage is indicated to avoid

accumulation of the drug. In such patients, measurement of the plasma concentration of the drug is advisable.

Regular blood counts are necessary whenever long-term therapy is used.

Special caution should be exercised in treating patients with conditions predisposing to folate deficiency.

Care should be taken when giving Bactrim to patients receiving sulphonylurea hypoglycaemic agents or coumarin anticoagulants as the action of these drugs may be increased.

Both trimethoprim and sulphamethoxazole are excreted in breast milk, but this does not contraindicate the use of Bactrim in lactating mothers.

Side-effects: At the recommended dosage, Bactrim is well tolerated. Nausea, vomiting, glossitis and skin rashes, including, rarely, erythema multiforme (Stevens-Johnson syndrome), can occur.

As Bactrim contains a sulphonamide, the possibility of blood dyscrasias like those associated with sulphonamides should be borne in mind. The changes reported with Bactrim mainly consist of thrombocytopenia, purpura, leucopenia, neutropenia and, very rarely, agranulocytosis. They have usually proved to be reversible on withdrawal of the drug. Elderly patients are more susceptible to these blood changes. During long-term therapy, isolated cases of megaloblastic changes in the bone marrow have been reported: these are reversible by folic acid therapy.

Local reactions to Bactrim IM Injection do not appear to be a clinical problem and mainly consist of mild to moderate pain at the injection site; induration is uncommon.

Effects of overdosage and their treatment: Symptoms of overdosage may include vomiting, mental and visual disturbances, petechiae, purpura and jaundice. Haematuria, crystalluria and anuria may occur in severe cases.

Treatment is symptomatic and may include gastric lavage and forced diuresis. Alkalinisation of the urine may aid the elimination of the sulphamethoxazole component of Bactrim.

Hypersensitivity reactions may require treatment with steroids. Calcium folinate, 3–6 mg intramuscularly for five to seven days, may be given to counteract the effects of trimethoprim on haemopoiesis.

Pharmaceutical precautions *Storage:* Bactrim IM Injection should be protected from light. The recommended maximum storage temperature is 30°C.

Additives: The ampoule solution of Bactrim IM Injection should not be diluted.

Legal category POM.

Package quantities Bactrim IM Injection, ampoules containing 160 mg trimethoprim and 800 mg sulphamethoxazole, in packings of 10.

Further information *Availability:* Bactrim is also available in tablets, Drapsules®, Double Strength tablets, paediatric tablets, adult suspension, paediatric syrup and, to hospitals only, as Bactrim for Infusion. See separate data sheets.

Product licence number 0031/0118.

BACTRIM® ROCHE FOR INFUSION

Approved name: Co-trimoxazole

Presentation Each 5 ml ampoule contains 80 mg trimethoprim and 400 mg sulphamethoxazole in a vehicle

containing 40% propylene glycol. The solution, which is almost colourless to very pale yellow, has a pH approximately 10.5.

Uses *Properties:* Bactrim is bactericidal *in vitro* to a wide range of Gram-positive and Gram-negative organisms, including *Streptococcus*, *Staphylococcus*, *Pneumococcus*, *Neisseria*, *Escherichia coli*, *Klebsiella*, *Proteus* spp., *Haemophilus*, *Salmonella*, *Shigella*, *Vibrio*, *Brucella*, *Pneumocystis carinii*, *Nocardia* and *Bordetella*. A particularly high degree of activity is exhibited against *Haemophilus influenzae*, *E. coli* and *Proteus* spp. making Bactrim particularly suitable for the treatment of chronic bronchitis and urinary tract infections.

Bactrim exerts its bactericidal action by the sequential blockade of two bacterial enzyme systems in the same metabolic pathway. The synergy thus produced accounts for the high degree of bactericidal activity.

Indications: Clinical experience with oral Bactrim indicates its therapeutic value in the following conditions: Respiratory tract infections. Renal and urinary tract infections. Genital tract infections. Gastro-intestinal tract infections caused by *Salmonella typhi* and *paratyphi* bacillary dysentery and cholera (as an adjuvant to fluid and electrolyte replacement). Skin and wound infection: Septicaemia and other infections caused by sensitive organisms including osteomyelitis, brucellosis and nocardiosis.

Parenteral administration of Bactrim for Infusion is indicated where oral dosage is not possible, for example Pre- and post-operative infections and severe trauma. Other clinical situations where the patient is unable to take or tolerate oral therapy.

Dosage and administration (ONLY to be given when DILUTED in an intravenous infusion – see below).

Adults and children over 12 years: 10 ml twice daily

Maximum dosage (for severe cases): 15 ml twice daily

Children up to 12 years: The recommended dosage is approximately 6 mg trimethoprim/kg body weight/day plus 30 mg sulphamethoxazole/kg body weight/day divided into 2 equal doses. As a guide, the following dosage regimes may be used:

6 weeks to 5 months: 1.25 ml twice daily.

6 months to 5 years: 2.5 ml twice daily.

6–12 years: 5 ml twice daily.

The dosage required for the treatment of *Pneumocystis carinii* pneumonitis is generally higher than that recommended for other conditions. In children a dosage of 20 mg trimethoprim/kg body weight/day plus 100 mg sulphamethoxazole/kg body weight/day, given in equally divided doses every six hours is suggested. For this reason, treatment should be undertaken only in facilities for monitoring of blood levels of the sulphamethoxazole component are available.

Duration of treatment: It is intended that Bactrim for Infusion should be used only during such a period as the patient is unable to accept oral therapy with Bactrim. In general, administration is unlikely to be required for more than a few days. It is recommended that the maximum dose (as indicated above) should not be administered for more than three successive days.

Mode of administration of Bactrim for Infusion: Bactrim for Infusion is suitable only for use as described below after addition to intravenous infusions. It is NOT suitable for any other route or method of administration.

Bactrim for Infusion must ONLY be given by the intravenous route and MUST BE DILUTED according to the schedule given below.

Bactrim for Infusion should only be mixed with one of the following infusion solutions: Dextrose Injection BP % and 10%. Laevulose Injection BP 5%. Compound sodium Lactate Injection BP (Hartmann's Solution). Compound Sodium Chloride Injection BPC 1959 Ringer's Solution). Sodium Chloride Injection BP. Sodium Chloride and Dextrose Injection BP (0.45% sodium chloride and 2.5% dextrose). Dextran 40 Injection BP. Dextran 70 Injection BP. No other agent should be added to or mixed with the infusion.

Dilution should be carried out as follows: One ampoule Bactrim for Infusion (5 ml) to 125 ml infusion solution.

Two ampoules Bactrim for Infusion (10 ml) to 250 ml infusion solution.

Three ampoules Bactrim for Infusion (15 ml) to 500 ml infusion solution.

Dilution should be carried out immediately before use. After addition of Bactrim for Infusion to the infusion solution, the mixture should be well shaken in order to ensure thorough mixing. Should visible turbidity or crystallisation appear in the solution at any time before or during the infusion, the mixture should be discarded.

It is suggested that the duration of the infusion should be of the order of 1½ hours, but this should be balanced against the fluid requirements of the patient.

Contra-indications, warnings, etc

Contra-indications: Bactrim is contra-indicated in patients showing marked liver parenchymal damage or blood dyscrasias and in severe renal insufficiency where repeated measurements of the plasma concentration cannot be performed. Bactrim should not be given to patients with history of sensitivity to sulphonamides or trimethoprim. Treatment must be immediately discontinued on the appearance of a skin rash.

Bactrim should not be given to premature babies nor during the first few weeks of life.

The drug should not be given during pregnancy. The usual caution in prescribing any drug for women of childbearing age should also be exercised with Bactrim.

Precautions: An adequate urinary output should be maintained. In cases with renal impairment a reduced or more widely spaced dosage is indicated to avoid accumulation of the drug. In such patients, measurement of the plasma concentration of the drug is advisable. Special caution should be exercised in treating patients with conditions predisposing to folate deficiency.

Care should be taken when giving Bactrim to patients receiving sulphonylurea hypoglycaemic agents or coumarin anticoagulants as the action of these drugs may be increased.

Side-effects: At the recommended dosage, Bactrim is well tolerated. Nausea, vomiting, glossitis and skin rashes, including, rarely, erythema multiforme (Stevens-Johnson syndrome), can occur.

As Bactrim contains a sulphonamide, the possibility of blood dyscrasias like those associated with sulphonamides should be borne in mind. The changes reported with Bactrim mainly consist of thrombocytopenia, purpura, leucopenia, neutropenia and, very rarely, agranulocytosis. They have usually proved to be reversible on withdrawal of the drug. Elderly patients are more susceptible to these blood changes. During long-term therapy, isolated cases of megaloblastic changes in the

bone marrow have been reported, these are reversible by folic acid therapy.

Bactrim for Infusion has occasionally given rise to local side-effects in the form of pain and phlebitis.

Effects of overdosage and their treatment: Symptoms of overdosage may include vomiting, mental and visual disturbances, petechiae, purpura and jaundice. Haematuria, crystalluria and anuria may occur in severe cases.

Treatment is symptomatic and may include forced diuresis. Alkalinisation of the urine may aid the elimination of the sulphamethoxazole component of Bactrim for Infusion.

Hypersensitivity reactions may require treatment with steroids. Calcium folinate. 3-6 mg intramuscularly for five to seven days, may be given to counteract the effects of trimethoprim on haemopoiesis.

Pharmaceutical precautions *Storage:* Bactrim for Infusion should be protected from light.

Legal category POM.

Package quantities Bactrim for Infusion, ampoules containing 80 mg trimethoprim and 400 mg sulphamethoxazole in 5 ml, in packings of 10.

Further information *Availability:* Bactrim for Infusion is available to hospitals only.

Bactrim is also available as Tablets (adult), Drapsules*, Double Strength Tablets, paediatric tablets, adult suspension and paediatric syrup and as Bactrim Roche IM Injection. See separate data sheets.

Product licence number 0031/0070.

BECOSYM*

Presentation Becosym Tablets: round, dark brown, film-coated tablets with BECOSYM imprinted on one face. They are known as Vitamin B Tablets, Compound, Strong.

Becosym Forte Tablets: round, dark brown, film-coated tablets with BECOSYM FORTE imprinted on one face.

Becosym Syrup: dark red-orange, fruit-flavoured syrup.

The vitamin content of these preparations is shown below.

	<i>Each tablet (mg)</i>	<i>Each Forte tablet (mg)</i>	<i>Syrup 5 ml (mg)</i>
Thiamine			
hydrochloride	5	15	5
Riboflavin	2	15	2
Nicotinamide	20	50	20
Pyridoxine			
hydrochloride	2	10	2

Uses *Properties:* The vitamin B-complex comprises a group of water-soluble factors more or less closely associated in their natural occurrence. It is known that nearly every vitamin of the B-complex forms part of a co-enzyme essential for the metabolism of protein, carbohydrate or fatty acid.

Manifestations of deficiency of the B-vitamins include glossitis, stomatitis, cheilosis, the heart manifestations of

beriberi, the skin manifestations of pellagra, corneal vascularisation and polyneuritis.

Indications: Becosym has been found of value in: clinical and subclinical vitamin deficiency states; supplementation of diet in old age and as an aid to recovery from illness and surgery; adjunct to treatment with broad-spectrum antibiotics.

Dosage and administration

Becosym and Becosym Forte Tablets and Becosym Syrup are for oral administration.

Becosym Syrup may be diluted with Syrup BP. Maintenance of stability cannot be guaranteed when Becosym Syrup is diluted.

	<i>Prophylactic</i>	<i>Therapeutic</i>
Adults	1–3 tablets or 5–15 ml syrup daily	2 or 3 Forte tablets daily
Children	5 to 15 ml syrup daily	1–3 tablets daily
Infants	5 ml syrup daily	

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions *Storage:* The recommended maximum storage temperature for Becosym, Becosym Forte Tablets and Becosym Syrup is 25°C. Becosym Syrup should be protected from light.

Legal category Tablets GSL
Forte Tablets GSL
Syrup GSL

Package quantities Becosym Tablets in packings of 100 and 500.

Becosym Forte Tablets in packings of 25, 100 and 250.

Becosym Syrup in packings of 100 ml.

Further information Nil.

Forte tablets 0031/5006
Syrup 0031/5007

BENADON*

Presentation Round, white tablets with 'B6 ROCHE' imprinted on one face, containing 20 mg pyridoxine hydrochloride.

Round, white tablets with 'BENADON' imprinted on one face and a single break bar on the other, containing 50 mg pyridoxine hydrochloride.

Uses *Properties:* Vitamin B₆ occurs naturally in three forms, namely pyridoxine, pyridoxal and pyridoxamine, which can be readily interconverted by animal tissues. As co-decarboxylases for several enzymes concerned with decarboxylation and transamination, the phosphates of pyridoxal and pyridoxamine are the functional forms of the vitamin. Thus the vitamin plays an important role in protein metabolism; it is also involved in fat metabolism.

Deficiency of the vitamin may manifest itself as anaemia, peripheral neuritis, convulsions, or lesions of the skin and mucous membranes.

Indications: Benadon is indicated in the treatment of: peripheral neuritis due to isoniazid therapy, or associated with pellagra; pregnancy sickness; radiation sickness;

pyridoxine-responsive anaemia; convulsions in infant which may be due to abnormally large requirements for pyridoxine.

Dosage and administration *Adults:* Usual therapeutic dose, 20–50 mg two or three times daily.

Acute deficiency, treatment of severe radiation or pregnancy sickness, blood disorders, 50–200 mg repeated as necessary.

Treatment of convulsions in children: 20–100 mg daily

Benadon Tablets are for oral administration.

Pharmaceutical precautions *Storage:* Recommended maximum storage temperature 30°C. Benadon Tablets should be protected from light.

Legal category GSL.

Package quantities Benadon Tablets 20 mg in packings of 100.

Benadon Tablets 50 mg in packings of 100.

Further information Nil.

BENERVA*

Presentation Round, white tablets with 'BENERVA' imprinted on one face, '3' in the centre of the other containing 3 mg thiamine hydrochloride.

Round, white tablets with 'BENERVA 10' imprinted on one face, containing 10 mg thiamine hydrochloride.

Round, white tablets with 'BENERVA 25' imprinted on one face, containing 25 mg thiamine hydrochloride.

Round, white tablets with 'BENERVA 50' imprinted on one face, containing 50 mg thiamine hydrochloride.

Round, white tablets with 'BENERVA 100' imprinted on one face, containing 100 mg thiamine hydrochloride.

Round, white tablets with 'ROCHE' imprinted on one face, containing 300 mg thiamine hydrochloride.

Ampoules containing 25 mg thiamine hydrochloride in 1 ml. The ampoule solution is almost colourless to faintly yellow.

Ampoules containing 100 mg thiamine hydrochloride in 1 ml. The ampoule solution is almost colourless to faintly yellow.

Uses *Properties:* Vitamin B₁ is particularly concerned with carbohydrate metabolism. When phosphorylated on the hydroxyl group it yields the pyrophosphate, co-carboxylase, which is concerned in pyruvate and lactate metabolism. The vitamin is essential for the nutrition of nerve cells, probably by promoting the oxidation of glucose within the central nervous system. Vitamin B₁ deficiency, or beriberi, is characterised by degeneration of the peripheral nerves with peripheral neuritis and by enlargement of the right heart, often accompanied by oedema.

Indications: Vitamin B₁ is specific in the treatment of beriberi.

It has been proved useful in the treatment of painful conditions such as: neuritis accompanying alcoholism and pregnancy; lumbago; sciatica; trigeminal neuralgia; optic neuritis; delirium tremens (large doses of Benerva combined with other vitamins should be given by injection).

Dosage and administration *Adults:* Prophylaxis, 3–10 mg daily.

Mild chronic deficiency, 10–25 mg daily.
Usual therapeutic dose, 10–50 mg daily.
Acute deficiency or treatment of such conditions as
mabgo and sciatica, 100–600 mg daily.

Children: If, on the recommendation of a physician, a
children's dosage is required, then it is suggested that 5–
10 mg daily may be given.

Benerva Tablets are for oral administration. Benerva
Ampoules are for intramuscular or intravenous injection.
Benerva Ampoule solution may be diluted with Water
for Injection. Maintenance of stability cannot be guar-
anteed when Benerva Ampoule solution is diluted.

Contra-indications, warnings, etc Although Be-
nerva is very well tolerated, it is now recognised that an
anaphylactic reaction may sometimes occur after an
injection of vitamin B₁, probably due to sensitisation to
the vitamin. A patient may tolerate one or more courses
of injections without trouble but then experience a
reaction to a later injection. Mild allergic phenomena,
such as sneezing or mild asthma, are warning signs that
further injection may give rise to anaphylactic shock. To
avoid this possibility it is advisable to start a second
course of injections with a dose considerably lower than
that previously used. Because of the above, injections of
B₁ should not be given intravenously, except in the case
of comatose patients who are often given large doses of
vitamins by intravenous drip.

Pharmaceutical precautions *Storage:* Recom-
mended maximum storage temperature 30°C. Benerva
tablets and Ampoules should be protected from light.

Legal category Tablets GSL.

BENERVA* COMPOUND

Presentation Round, yellow tablets with 'ROCHE'
imprinted on one face, containing 1 mg thiamine
hydrochloride, 1 mg riboflavin and 15 mg nicotinamide.

Uses *Properties:* Benerva Compound Tablets contain
the three principal members of the vitamin B-complex.

The vitamin B-complex comprises a group of water-
soluble factors more or less closely associated in their
natural occurrence. It is known that nearly every vitamin
of the B-complex forms part of a co-enzyme essential for
the metabolism of protein, carbohydrate or fatty acid.

Indications: Treatment of minor degrees of vitamin B-
complex deficiency.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions *Storage:* Recom-
mended maximum storage temperature 25°C. Benerva
Compound Tablets should be protected from light.

Legal category GSL.

Dosage and administration

	<i>Prophylactic</i>	<i>Therapeutic</i>
Adults	1–2 tablets daily	1–3 tablets three times daily
Children:		
Over 12 years	1½–2 tablets daily	1½–2 tablets three times daily
Under 12 years	½–1 tablet daily	½–1 tablet three times daily

Benerva Compound Tablets are for oral administration.

Package quantities Benerva Compound Tablets in
packings of 200.

Further information Nil.

Product licence number 0031/5009.

DALMANE*

Presentation Capsules with opaque grey cap and
opaque yellow body with 'ROCHE 15' printed in red on
both cap and body, containing 16.4 mg flurazepam
monohydrochloride (equivalent to 15 mg flurazepam).
Capsules with black cap and opaque grey body with
'ROCHE 30' printed in red on both cap and body,
containing 32.8 mg flurazepam monohydrochloride
(equivalent to 30 mg flurazepam).

Uses *Properties:* Sleep laboratory studies have shown
that flurazepam significantly increases total sleep time
by reducing sleep induction time and maintaining sleep
with a reduced number of nocturnal awakenings. All-
night studies on healthy subjects have shown that a 30
mg dose produces only minimal changes in the pattern
of rapid eye movement (REM) sleep and that there is no
REM-rebound on withdrawal of the drug. Depression of
stage IV sleep has occasionally been noted.

Indications: Insomnia – difficulty in falling asleep,
frequent nocturnal awakenings and/or early morning
awakening. Sleep disturbances due to organic conditions
in conjunction with specific therapy.

Dosage and administration *Adults:* The dosage
required may vary according to the severity of the
insomnia and the patient's response. As a guide, we
would recommend that the following doses are taken
before retiring.

Severe insomnia: 30 mg.

Moderate to severe insomnia: 15 or 30 mg.

Mild insomnia: 15 mg.

Elderly patients: 15 mg.

Children: No dosage recommendations are made for the
administration of Dalmane to children.

Dalmane Capsules are for oral administration.

Contra-indications, warnings, etc *Precautions:*
With Dalmane, as with all other drugs acting on the
central nervous system, patients should avoid taking

alcohol while under treatment, since the individual response cannot be foreseen. Like all medicaments of this type, Dalmane may modify patients' reactions (driving ability, operation of machinery, etc) to a varying extent, depending on dosage and individual susceptibility.

The use of high doses of benzodiazepines, especially over prolonged periods, may sometimes lead to dependence, particularly in patients with a history of alcoholism or drug abuse. Treatment in these cases should be withdrawn gradually.

Results obtained in trials with several generations of rats and rabbits indicate that no danger of teratogenic effects need be expected from therapeutic doses of Dalmane. Nevertheless, the established medical principle of prescribing medicaments in early pregnancy only when absolutely indicated should be observed.

Treatment in elderly patients should be initiated with 15 mg Dalmane until the response can be judged.

Side-effects: Dalmane is well tolerated. However, morning drowsiness, dizziness and ataxia may occur. Occasionally patients treated with Dalmane experience a bitter after-taste. Extensive clinical and laboratory investigations have revealed no significant changes in the blood picture or liver function.

Effects of overdosage and their treatment: As with other benzodiazepine drugs, overdosage should not present undue problems of management or threat to life. Drowsiness, ataxia and slurred speech are symptoms of overdosage. Treatment is symptomatic, but gastric lavage may be useful if performed soon after ingestion.

Pharmaceutical precautions *Storage:* No special precautions are required for Dalmane capsules stored in amber-glass or plastic bottles.

Legal category POM.

Package quantities Dalmane Capsules 15 mg in packings of 100 and 500.

Dalmane Capsules 30 mg in packings of 100 and 500.

Further information Nil.

Capsules 30 mg 0031/0066.

DECLINAX®

Presentation Round, white tablets with 'ROCHE 10' imprinted on one face and a single break bar on the other, containing 12.8 mg debrisoquine sulphate (equivalent to 10 mg base).

Round, pale blue tablets with 'ROCHE 20' imprinted on one face and two break bars on the other, containing 25.6 mg debrisoquine sulphate (equivalent to 20 mg base).

Uses *Properties:* Declinax lowers blood pressure markedly and promptly in the hypertensive patient. It does this by blocking the transmission of sympathetic nerve impulses at the nerve terminals, thereby decreasing peripheral vascular resistance. Reduction in post-ganglionic sympathetic transmission is achieved by interfering with the physiological release of noradrenaline, without depleting major catecholamine stores in cardiovascular tissues and without impairing the cardiac contractile mechanism. The action, as with other potent antihypertensive agents, is most marked in the standing position. Declinax normally acts within 4–10 hours and

its effects usually last for 9–24 hours, although an occasional patient may show a longer response. There is no accumulation on maintenance dosage.

Indications: Declinax is indicated for the treatment of all grades of hypertension. It can be given either alone or together with other antihypertensive drugs or diuretics.

Dosage and administration *Adults: Mild to moderate hypertension:* 10 mg once or twice daily. This dose can be increased by 10 mg at three-day intervals. The total dose usually falls within the range 20–60 mg daily. *Severe hypertension:* 20 mg once or twice daily. The dose can be increased, depending on response, by 10–20 mg every three or four days provided a close check is kept on the blood pressure. The total dose usually falls within the range 40–120 mg, but in cases of very severe hypertension 300 mg or more daily may be given.

Should postural hypotension occur with a dosage that controls the blood pressure, the total daily dose should be adjusted to give a small dose in the morning, a relatively large dose at midday and a moderate evening dose.

Children: No dosage recommendations are made for the administration of Declinax to children.

Declinax Tablets are for oral administration.

Contra-indications, warnings, etc *Precautions:* Declinax should be used with caution in those patients with renal insufficiency and should not be given to patients with a pheochromocytoma. Patients on antihypertensive drugs often have a lower blood pressure in warm weather, therefore in hot climates their dose of Declinax may need to be reduced. Evidence from both animal experiments and clinical observation suggests that the hypotensive action of adrenergic neurone blocking drugs such as Declinax may be inhibited by simultaneous treatment with tricyclic antidepressants. Extra care should be taken when prescribing antihypertensive drugs in patients being treated with levodopa. Patients taking Declinax are sensitive to sympathomimetic drugs.

Side-effects: Declinax is well tolerated. Overdosage causes postural hypotension, most noticeable in the early morning or with long standing and associated with weakness, giddiness and fatigue. The patient should be warned of the possibility of these symptoms occurring. This can be minimised by reducing the dose. Other side effects include malaise, nausea, headache, sweating, failure of ejaculation in the male, and sometime frequency of micturition and nocturia. Diarrhoea, common with some other antihypertensive agents, is seen only very rarely.

Effects of overdosage and their treatment: Excessive fall in blood pressure will be shown by orthostatic collapse. This will usually respond rapidly to placing the patient in a recumbent position.

Pharmaceutical precautions *Storage:* Declinax Tablets should be stored in well-closed containers.

Legal category POM.

Package quantities Declinax Tablets 10 mg in packings of 100 and 500.

Declinax Tablets 20 mg in packings of 100 and 500.

Further information Nil.

Tablets 20 mg 0031/5060

'ROMORAN' ROCHE

resentation Round, white tablets with 'ROCHE' printed on one face, two concentric circles on the other, containing 1.5 mg levorphanol tartrate. Ampoules containing 2 mg levorphanol tartrate in 1 ml. The ampoule solution is colourless to pale yellow.

Uses Properties: Dromoran Roche is a more potent and longer-acting analgesic than morphine. The analgesic effect begins within 10–30 minutes after administration and may continue for as long as 8 hours. Dromoran Roche is effective by mouth. Only in acute pain, when it is desirable to obtain rapid relief, is it necessary to give the drug by injection.

indications: Relief of severe pain; pre-operative medication; supplement to nitrous oxide/oxygen anaesthesia.

Dosage and administration Adults: *Oral:* Single dose of 1.5–4.5 mg once or twice daily.

Subcutaneous or intramuscular injection: The usual single dose is 2–4 mg.

Intravenous injection: 1–2 mg.

Supplement to nitrous oxide/oxygen anaesthesia: Total dose usually 1.5–2 mg given in divided doses of 0.25–0.5 mg.

Children: Paediatric dose not established.

Dromoran Roche Tablets are for oral administration.

Dromoran Roche Ampoules are for intramuscular, intravenous or subcutaneous injection.

Dromoran Roche Ampoule solution may be diluted with Water for Injection.

Maintenance of stability cannot be guaranteed when Dromoran Roche Ampoule solution is diluted.

Contra-indications, warnings, etc

Contra-indications: Dromoran Roche should not be given to comatose patients or to patients with respiratory depression or obstructive airways disease. It should not be administered to patients who are receiving monoamine oxidase inhibitors or within two weeks of their withdrawal.

Precautions: Dromoran Roche should only be given with caution, and in reduced dosage, to neonates and premature infants, elderly and debilitated patients, and in patients with head injuries, severe hepatic or renal impairment, biliary tract disorders, hypothyroidism, adrenocortical insufficiency, shock, prostatic hypertrophy, and supraventricular tachycardia.

Caution is also required in patients exhibiting acute alcoholism, raised intracranial pressure or convulsive disorders. Dromoran Roche depresses respiratory function and should be administered with particular care in patients with respiratory insufficiency.

The effects of Dromoran Roche may be potentiated by concurrent administration of other central nervous system depressants, including anaesthetic agents. Concurrent administration of Dromoran Roche with phenothiazines may induce severe hypotension. Patients should be instructed to avoid alcohol while under treatment, since the individual response cannot be foreseen.

Dromoran Roche may modify patients' reactions (driving ability, operation of machinery, etc.) to a varying extent, depending on dosage, administration and individual susceptibility.

There is little reported human usage of Dromoran in pregnancy. Although no adverse effects have been found in animals, the established medical principle of

prescribing medicaments in early pregnancy only when absolutely indicated should be observed.

Dromoran Roche crosses the placenta and may also be secreted in breast milk. This should be borne in mind when considering its use in patients during pregnancy or breast feeding. Administration in labour may cause respiratory depression in the newborn infant.

Repeated administration of Dromoran Roche may induce tolerance to the drug, with a tendency to increasing dosage requirements to obtain the desired effect, or to physical and psychological dependence of the morphine type, with the development of withdrawal symptoms after abrupt cessation of therapy. Cross-tolerance between narcotic analgesics can occur.

Side-effects: Dromoran Roche is usually well tolerated. Neither circulatory disturbances nor effects on the blood-pictures are likely. Appetite, gastro-intestinal and renal functions are less likely to be affected by Dromoran Roche than by morphine; however, nausea, vomiting, constipation and confusion may be troublesome. The drug has a less pronounced hypnotic effect than morphine, and is, therefore, useful for the relief of pain during the day.

Effects of overdosage and their treatment: In overdosage pin-point pupils, depressed respiration and impaired level of consciousness or coma may occur. In severe poisoning there may be dilatation of pupils, shock, severe respiratory depression and pulmonary oedema.

Gastric aspiration and lavage should be performed soon after ingestion and intensive supportive therapy carried out. Lorfan* 1–2 mg i.v., naloxone and nalorphine are antidotes.

Pharmaceutical precautions *Storage:* The recommended maximum storage temperature for Dromoran Roche Ampoules is 25°C; the Ampoules should be protected from light.

Dromoran Roche Tablets in blister packs should be stored in a dry place.

Legal category POM: MDA.

Package quantities Dromoran Roche Tablets in cartons of 500, each carton containing 10 packs of 50 tablets in blister strips of 5 tablets.

Dromoran Roche Ampoules in packings of 10.

Further information Nil.

EFUDIX* ▼

Presentation White, opaque cream containing 5% w/w fluorouracil.

Uses Properties: Efudix is a topical cytostatic preparation which exerts a beneficial therapeutic effect on neoplastic and pre-neoplastic skin lesions without damaging normal skin. The pattern of response follows this sequence: erythema, vesiculation, erosion, ulceration, necrosis and epithelialisation.

Indications: Efudix is used for the topical treatment of superficial pre-malignant and malignant skin lesions; keratoses, including senile, actinic and arsenical forms; keratoacanthoma; Bowen's disease; superficial basal-cell carcinoma.

Deep, penetrating or nodular basal cell and squamous

cell carcinomas do not usually respond to Efudix therapy. It should be used only as a palliative therapy in such cases where no other form of treatment is possible.

Dosage and administration *Pre-malignant conditions:* The cream should be applied thinly to the affected area once or twice daily; an occlusive dressing is not essential.

Malignant conditions: The cream should be applied once or twice daily under an occlusive dressing where this is practicable.

The cream should not harm healthy skin. Treatment should be continued until there is a marked inflammatory response from the treated area, preferably with some erosion in the case of pre-malignant conditions. Severe discomfort may be alleviated by the use of topical steroid cream. The usual duration of treatment for an initial course of therapy is three to four weeks, but this may be prolonged. Lesions on the face usually respond more quickly than those on the trunk or lower limbs whilst lesions on the hands and forearms respond more slowly. Healing may not be complete until one or two months after therapy is stopped.

Efudix Cream is for topical application.

Efudix Cream should not be diluted.

Contra-indications, warnings, etc

Contra-indications: Efudix is contra-indicated during pregnancy and in patients with known hypersensitivity to Efudix or parabens.

Precautions: Efudix is for topical use only and care should be taken to avoid contact with mucous membranes or the eyes. The hands should be washed carefully after applying the cream.

The total area of skin being treated with Efudix at any one time should not exceed 500 cm² (approx 23 × 23 cm). Larger areas should be treated a section at a time.

Side-effects: Efudix is well tolerated and systemic toxicity is negligible. Transient erythema may occur in healthy skin surrounding the area being treated. Pre-existing subclinical lesions may become apparent. Exposure to sunlight may increase the intensity of the reaction.

Effects of overdosage and their treatment: If Efudix is accidentally ingested, signs of fluorouracil overdosage may include nausea, vomiting and diarrhoea. Stomatitis and blood dyscrasias may occur in severe cases. Appropriate measures should be taken for the prevention of systemic infection and daily white cell counts should be performed.

Pharmaceutical precautions *Storage:* The recommended maximum storage temperature for Efudix Cream is 30°C.

Legal category POM.

Package quantities Efudix Cream in tubes of 20 g.

Further information Efudix should be used only under specialist medical supervision.

Availability: Efudix Cream is available through hospital pharmacies for use in hospitals and hospital clinics and can be supplied to retail pharmacies for dispensing prescriptions for patients whose treatment has been initiated in hospital practice.

Product licence number 0031/0027.

EPHYNAL*

Presentation Round, white tablets with 'EPHYNA' imprinted on one face, the other being plain, containing 3 mg tocopheryl acetate.

Round, white tablets with 'EPHYNAL' imprinted on one face and 'TEN' on the other, containing 10 mg tocopheryl acetate.

Round, white tablets with 'EPHYNAL 50' imprinted on one face with a single break bar on the other containing 50 mg tocopheryl acetate.

Round, white to pale cream tablets with 'EPHYNAL 200' imprinted on one face and a single break bar on the other, containing 200 mg tocopheryl acetate.

Uses *Properties:* Ephyenal is a synthetic vitamin E preparation. The exact role of vitamin E in the animal organism has not yet been established. Vitamin E is known to exert an important physiological function as an anti-oxidant for fats, with a sparing action on vitamins A, carotenoids and on unsaturated fatty acids. Other work has demonstrated that vitamin E is connected with the maintenance of certain factors essential for the normal metabolic cycle.

Vitamin E deficiency produces a wide variety of manifestations in many organs and tissues of the body of most animal species that have been studied.

Indications: Ephyenal is indicated in high dosage for the treatment of intermittent claudication of moderate severity.

There is occasionally evidence of tocopheryl deficiency resulting in clinical signs in the following disorders: malabsorption syndromes, e.g. fibrocystic diseases of the pancreas; sprue; premature infants on unsupplemented artificial feeds.

Dosage and administration *Adults:* The recommended daily intake as a vitamin is from 3 to 15 mg but more may be required when large amounts of unsaturated fats are contained in the diet.

For treatment of intermittent claudication doses of 400–600 mg a day should be administered for three months or more.

Children (infants): 1–10 mg/kg body weight daily.

Ephyenal Tablets are for oral administration.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions *Storage:* Ephyenal Tablets should be stored in well-closed containers.

Legal category GSL.

Package quantities Ephyenal Tablets 3 mg in packings of 100.

Ephyenal Tablets 10 mg in packings of 100.

Ephyenal Tablets 50 mg in packings of 100.

Ephyenal Tablets 200 mg in packings of 50.

FANSIDAR* ▼

Presentation Round, white tablets with ROCHE and a hexagon imprinted on one face and two break bars on the other, containing 500 mg sulfadoxine and 25 mg pyrimethamine.

Properties: The mode of action of Fansidar is based on the reciprocal potentiation of its two components. Fansidar blocks the action of two enzymes which catalyse consecutive stages in the biosynthesis of folic acid in malaria parasites. Larger doses of the components of Fansidar are necessary if they are given independently and the effect obtained is inferior to that of the combination.

Fansidar is effective against plasmodial strains which are resistant to chloroquine and/or pyrimethamine and other antifolate preparations.

With Fansidar, the danger of emergence of resistance is reduced. Fansidar affects all developmental stages of the parasites. It has a prolonged action, yet effective plasma concentrations are rapidly attained after a single dose. Trophozoites and schizonts quickly disappear from the blood. Pre-erythrocytic stages are also affected and the gametocytes, although increased in number, are rendered much less infective for the vector. A protective effect persists for up to two to four weeks depending on the dose given and the immune state of the subject.

Indications: Malaria prophylaxis in patients who are unable to tolerate chloroquine or in high-risk patients in areas where resistance to this and other antimalarials is known to occur.

Malarial attacks and symptoms produced by: *Plasmodium falciparum*, *Plasmodium vivax*, *Plasmodium malariae*, *Plasmodium ovale*.

Dosage and administration *Prophylactic management:* The following dose of Fansidar should be taken every seven days:

Adults: 1 tablet.

Children 9–14 years: $\frac{3}{4}$ tablet.

4–8 years: $\frac{1}{2}$ tablet.

Under 4 years: $\frac{1}{4}$ tablet.

Regular dosage is important for continuous protection to be maintained. Routine measures to protect against mosquito bites should not be omitted.

Fansidar prophylaxis should be started a few days before entering the endemic area; this will enable an alternative drug to be selected in the infrequent case where Fansidar is poorly tolerated. **IMPORTANT:** Fansidar prophylaxis should be continued for four to six weeks after returning to a non-malarious area to ensure elimination of possible *falciparum* infections (malignant malaria). However, as with other prophylactic drugs, infections of benign malaria (*vivax* and *malariae* infections) may give rise to clinical attacks up to several months after return, despite regular prophylaxis. *Travelers should be instructed to report to a doctor any fever that occurs during or after their stay in a malarious area.*

Curative treatment of malaria: The appropriate amount of the drug is given in one single dose. This dose should not be repeated for at least seven days.

Adults (according to body weight): 2 to 3 tablets.

Children 9–14 years: 2 tablets.

4–8 years: 1 tablet.

Under 4 years: $\frac{1}{2}$ tablet.

In very severe cases, quinine may be added, preferably parenterally. An adequate supply of fluids and electrolytes should be maintained. Cerebral malaria may require additional corticosteroid therapy.

Fansidar tablets are for oral administration.

Contra-indications, warnings, etc

Contra-indications: Patients with known sulphonamide hypersensitivity or having severe liver or kidney dys-

function. Treatment must be immediately discontinued on the appearance of a skin rash.

Because of the risk of increased neonatal bilirubin levels, Fansidar should not be given during the week before the expected date of delivery. Like all other preparations containing sulphonamides, Fansidar is contra-indicated in premature babies and during the first few weeks of life. Both pyrimethamine and sulfadoxine are secreted in breast milk, therefore Fansidar should not be prescribed to lactating mothers.

Precautions: There is a theoretical risk of foetal malformations with all folate inhibitors given during pregnancy. If pregnancy cannot be excluded, possible risks should be balanced against the expected therapeutic benefit.

Side-effects: Fansidar is usually well tolerated. Side-effects in the form of skin rashes, gastro-intestinal disturbances or allergic-toxic skin reactions may occasionally occur as with other preparations containing sulphonamides or pyrimethamine.

Blood dyscrasias may rarely occur over long periods of administration, hence regular blood counts are recommended during long-term prophylaxis. In this respect particular care should be taken if treatment with other preparations containing folate inhibitors (e.g. cotrimoxazole, methotrexate, anticonvulsants) is given concomitantly.

Adverse reactions occurring after the administration of the sulfadoxine component of Fansidar are not normally more prolonged than those occurring after shorter-acting sulphonamides despite the continued presence of the drug in the body.

Effects of overdosage and their treatment: Treatment is symptomatic and may include forced diuresis. Vigorous gastric lavage should be carried out as early as possible after ingestion. Alkalinization of the urine may aid elimination of the sulfadoxine component of Fansidar. Possible convulsions due to the pyrimethamine components of Fansidar should be watched for and may require anticonvulsant therapy.

Hypersensitivity reactions may require treatment with steroids. Calcium folinate may be given to counteract the effects of pyrimethamine on haemopoiesis.

Pharmaceutical precautions *Storage:* No special precautions are required.

Legal category POM.

Package quantities Fansidar tablets are available in foil strips in packs of 12 and 150.

Further information Nil.

Product licence number 0031/5097.

FLUORO-URACIL ROCHE

Presentation Ampoules containing 250 mg fluoro-uracil in the form of the sodium salt in 10 ml Water for Injection BP. The ampoule solution is colourless to slightly yellow.

Capsules with powder blue opaque cap and medium orange opaque body with ROCHE printed in black along both cap and body, containing 250 mg fluorouracil.

Uses **Properties:** Fluoro-uracil Roche, a cytostatic agent, is a fluorinated pyrimidine belonging to the category of antimetabolites. It inhibits cell division by

interfering with the synthesis of deoxyribonucleic acid (DNA) and to a lesser extent of ribonucleic acid (RNA).

Indications: The palliative treatment of carcinoma.

Dosage and administration Various techniques are employed when using Fluoro-uracil Roche in the treatment of carcinoma. The following examples are given for guidance.

Adults: By the intravenous route: Fluoro-uracil Roche may be administered by intravenous infusion or by intravenous injection. Dosages are generally based on the patient's body weight. If the patient is obese or there has been a spurious gain due to oedema, ascites or other forms of fluid retention, the patient's ideal weight should be used in calculating the dosage. The initial doses given below should be reduced by one-third to a half if the following conditions are present: poor nutritional state; after major surgery (within the previous 30 days); inadequate bone-marrow function (anaemia, leucopenia with white cell count less than 3,500 per mm³, thrombocytopenia with platelet count less than 100,000 per mm³); impaired hepatic or renal function.

Initial treatment: This may be in the form of an infusion or injection, the former usually being preferred because of lesser toxicity.

Infusion: A daily dose of 15 mg/kg but not more than 1 g per infusion is diluted in 500 ml dextrose 5% solution and given by intravenous infusion at the rate of 40 drops per minute over four hours. This daily dose is given on successive days until toxicity occurs or until 12–15 g have been given. This sequence of injections constitutes a 'course' of therapy. Some patients have received up to 30 g at a maximum rate of 1 g daily. The daily dose should never exceed 1 g. An interval of four to six weeks should be allowed between any two 'courses' of Fluoro-uracil Roche.

Injection: A dose of 12 mg/kg i.v. daily on three consecutive days. If there are no signs of toxicity the patient receives 6 mg/kg i.v. on the fifth, seventh and ninth days. If toxicity occurs the signs should be allowed to regress before further doses are administered.

Maintenance therapy consists of 5–15 mg/kg i.v. once weekly.

A more recent alternative method is to give 15 mg/kg i.v. once a week throughout the course of treatment.

This obviates the need for an initial period of daily administration.

Regional perfusion intra-arterially: Continuous infusion of Fluoro-uracil Roche into an artery supplying a localised growth has been shown to produce a better result in some tumours than would have been expected from systemic administration by the intravenous route, together with a decrease in toxicity. The usual dose is 5–7.5 mg/kg daily.

In combination with radiotherapy: Irradiation combined with Fluoro-uracil Roche has been found to be useful in the treatment of certain types of metastatic lesions in the lungs and for relief of pain caused by recurrent, inoperable growth. The standard dose of Fluoro-uracil Roche is used.

By the oral route: Fluoro-uracil Roche may be administered orally using either the capsule or the ampoule solution.

Oral administration is not recommended when Fluoro-uracil Roche is being used initially as the sole agent in palliative treatment of carcinoma. Oral administration may be useful in: palliative therapy employing a combi-

nation of drugs; long-term maintenance or post-operative prophylactic therapy in weekly doses; and when therapy with Fluoro-uracil Roche is indicated, but it is impracticable to administer the drug parenterally.

The usual dosage for maintenance treatment is 15 mg/kg once weekly. For palliative therapy a more rapid onset of therapeutic effect may be obtained by giving a daily dose of 15 mg/kg on six successive days. This is followed by maintenance therapy of 15 mg/kg once weekly. The daily dose should not exceed 1 g.

The capsules should be taken with water after a meal.

The solution may be mixed with fruit juice or other similar beverages immediately before oral ingestion to mask its rather bitter taste. Multi-dose preparations must not be made up.

Children: No dosage recommendations are made for the administration of Fluoro-uracil Roche to children.

Fluoro-uracil Roche Ampoules are for intra-arterial intravenous or oral administration.

Fluoro-uracil Roche capsules are for oral administration.

Contra-indications, warnings, etc

Contra-indications: Fluoro-uracil Roche should not normally be administered to patients who are pregnant or to mothers who are breast-feeding.

Precautions: Fluoro-uracil Roche should be used with great care in debilitated patients.

The margin between the effective and toxic doses of Fluoro-uracil Roche is narrow and a therapeutic response is unlikely without some evidence of toxicity. Even with meticulous selection of patients and careful adjustment of dosage, there may be severe haematological toxicity and gastro-intestinal haemorrhage. Severe toxicity is more likely in poor-risk patients.

Treatment should be discontinued promptly whenever one of the following signs of toxicity appears: Leucopenia (WBC under 3,500 per mm³). Thrombocytopenia (platelets under 100,000 per mm³). Stomatitis (the first small ulceration at the inner margin of the lips is a sign for stopping treatment). Severe diarrhoea (frequent bowel movements and watery stools). Gastro-intestinal ulceration and bleeding. Haemorrhage at any site.

Isolated cases of angina, ECG abnormalities and rarely myocardial infarction have been reported following Fluoro-uracil administration. Caution should therefore be exercised in treating patients who experience chest pain during courses of therapy, or patients with a history of heart disease.

Side-effects: During treatment, diarrhoea, nausea and vomiting commonly occur, but may be controlled by the use of appropriate drugs.

Leucopenia usually follows an adequate course of treatment with Fluoro-uracil Roche. The lowest white cell count commonly occurs between the seventh and fourteenth days after the first dose, but it may be delayed for as long as the twentieth day. By the thirtieth day, the count has usually returned to the normal range. Because of the importance of leucopenia, the white cell count should be checked frequently throughout the course. If it falls, it is advisable to obtain differential counts. If the total is less than 2,000 per mm³, and especially if there is a granulocytopenia, it is recommended that the patient be placed in protective isolation in the hospital and treated with appropriate measures for the prevention of systemic infection.

Alopecia and dermatitis may occur in a substantial proportion of cases. Female patients particularly should

warned as to the possibility of alopecia. Since the speca seems to be reversible, special measures do not em to be indicated.

fects of overdosage and their treatment: Signs and mptoms are qualitatively similar to the side-effects, id similar measures should be taken to treat them.

harmaceutical precautions *Storage:* Fluoro-uracil oche Ampoule solution should be stored between 10°C and 30°C and should be protected from light.

No special precautions are required for Fluoro-uracil oche capsules stored in amber glass or plastic ontainers.

dditives: Fluoro-uracil Roche Ampoule solution may e diluted with Dextrose Injection or Water for Injection P immediately before parenteral use.

Fluoro-uracil Roche Ampoule solution may be diluted ith fruit juice or other similar beverages immediately efore use to facilitate ingestion by the oral route. Fluoro-racil Roche ampoule solution must not be made up into ultli-dose preparations.

egal category POM.

ackage quantities Fluoro-uracil Roche Ampoules i packings of 10.

Fluoro-uracil Roche capsules in packings of 50.

urther information It is recommended that Fluoro-racil Roche be given only by or under the supervision f a physician who is experienced in cancer chemo-herapy and who is well versed in the use of potent ntimetabolites. Because of the possibiity of severe toxic eactions, all patients should be admitted to hospital for nitial treatment.

Availability: Fluoro-uracil Roche Ampoules are available hrough hospital pharmacies for use in hospitals and ospital clinics and can be supplied to retail chemists for ispensing prescriptions for patients whose treatment as been initiated in hospital practice.

Capsules 0031/0139

GANTRISIN®

Presentation Round, white tablets with 'Gantrisin' nprinted on one face, containing 500 mg sulpha-jrazole.

White, fruit-flavoured syrup containing 591.5 mg f'-acetylsulphafurazole (equivalent to 500 mg sulpha-jrazole) in 5 ml.

Uses Properties: Gantrisin is a sulphonamide which is characterised by high therapeutic activity, ready solubil-y and low toxicity. High concentrations are obtained in re blood and urine. Its relatively high solubility, even in lightly acid media, reduces the likelihood of crystalluria nd renal complications to a minimum. It is effective gainst sulphonamide-sensitive organisms.

indications: Infections of the respiratory tract and ear, fections of the urinary tract, bacillary dysentery; skin nd soft tissue infections, prophylactic treatment of econdary infections.

Dosage and administration

	Tablets		Syrup in ml	
	Initial	Mainten- ance 4-6 hourly	Initial	Mainten- ance 4-6 hourly
Adults and older children	4	2	20	10
Children 9- 14 years	3	1½	15	7.5
5-6 years	2	1	10	5
2-4 years	1	½	5	2.5
Infants			2.5	1.25

For severe infections twice these doses are given.

Gantrisin Tablets and Syrup are for oral administration.

Gantrisin Syrup may be diluted with Syrup BP.

Maintenance of stability cannot be guaranteed when Gantrisin Syrup is diluted.

Contra-indications, warnings, etc

Contra-indications: Like all other sulphonamides, Gan-trisin is contra-indicated in premature and newborn infants during the first month of life. Because of immaturity of liver enzyme systems, such infants may have difficulty in conjugating sulphonamides normally.

Gantrisin should not be given to patients with a history of sulphonamide sensitivity.

Side-effects: Clinical experience has shown Gantrisin to be exceptionally free from serious side-effects, although, occasionally, patients may experience the reactions common to sulphonamides, including nausea, vomiting, glossitis and skin rashes. Leucopenia may rarely occur over long periods of treatment, hence regular blood counts are recommended during long-term treatment.

Effects of overdosage and their treatment: Symptoms of overdosage may include vomiting, mental and visual disturbances, petechiae, purpura and jaundice. In acute cases, haematuria, crystalluria and anuria may occur.

Treatment is symptomatic; gastric lavage may be useful. An adequate fluid intake should be maintained and the urine made alkaline. Hypersensitivity reactions may require treatment with steroids.

Pharmaceutical precautions *Storage:* All Gantrisin preparations should be protected from light. Gantrisin Tablets should be stored in well-closed containers. The recommended maximum storage temperature of Gantrisin Syrup is 25°C; the Syrup should be stored in glass containers.

Legal category POM.

Package quantities Gantrisin Tablets in packings of 100.

Gantrisin Syrup in packings of 100 ml.

Further information Nil.

Tablets 0031/5019
Syrup 0031/5020

GLUTRIL®

Presentation Round, white tablets with 'ROCHE' imprinted on one face and a single break bar on the other, containing 25 mg glibornuride.

Uses Properties: Glutril is an effective and long-acting hypoglycaemic agent. In common with other substances of the sulphonylurea group, the action of Glutril is attributed to the release of endogenous insulin from the beta cells of the pancreatic islets of Langerhans. There is evidence that Glutril also exhibits extra-pancreatic activity.

Indications: The treatment of maturity-onset diabetes mellitus which is not adequately controlled by dietary measures alone and does not require insulin. Glutril is particularly suitable for the treatment of elderly maturity-onset diabetics.

Dosage and administration Adults: The dosage of Glutril varies from individual to individual and only a guide can be given.

Patients not previously treated with hypoglycaemic agents: Treatment should begin with $\frac{1}{2}$ tablet (12.5 mg) Glutril daily taken with breakfast. This dosage may be increased to 1 tablet (25 mg) or 2 tablets (50 mg) daily if necessary. Some patients may require a higher dose to control hyperglycaemia and they may be given $2\frac{1}{2}$ (62.5 mg) or 3 tablets (75 mg) daily.

Where higher doses are required, the total daily dose should be divided. Two tablets should be administered in the morning and the remainder of the dose in the evening.

It is recommended that the dose of Glutril should not exceed 75 mg daily.

Oral hypoglycaemic agents of the biguanide type may be added to the Glutril regimen in instances where a dose of 75 mg daily is reached without satisfactory control of hyperglycaemia.

Patients previously treated with oral hypoglycaemic agents: Patients may be transferred from other oral hypoglycaemic agents to Glutril, the dosage of the latter being based on the amount of the previous therapy required to control hyperglycaemia. The following equivalents may be used as a basis:

Glutril 25 mg is equivalent to 1,000 mg tolbutamide, 250 mg chlorpropamide or 5 mg glibenclamide.

Patients previously treated with insulin: Some patients previously treated with low doses of insulin (less than 40 units daily) may be suitable for transfer to Glutril therapy.

Children: No dosage recommendations are made for the administration of Glutril to children.

Glutril Tablets are for oral administration.

Contra-indications, warnings, etc

Contra-indications: Glutril is contra-indicated in the presence of ketoacidosis and severe renal, hepatic, adrenal and thyroid dysfunction. It should not be used in patients with known intolerance to sulphonylurea derivatives. Juvenile diabetes should not be treated with Glutril. Glutril is not indicated during pregnancy.

Precautions: The action of oral hypoglycaemic agents including Glutril may be influenced by other therapeutic agents. Sulphonamides, salicylates, phenylbutazone, coumarin derivatives, adrenergic beta-receptor blocking drugs, monoamine oxidase inhibitors, cyclophosphamide, chloramphenicol, and tuberculostatics may enhance the effects of Glutril whilst thiazide diuretics, frusemide, ethacrynic acid, diazoxide, oral contraceptives containing oestrogens and corticosteroids may diminish its effects. Alcohol and tetracycline derivatives may also alter the action of Glutril.

In patients suffering from intercurrent infections or trauma, the dosage of Glutril may need to be adjusted. If

such complications are severe, diabetic control may be lost and this will necessitate the withdrawal of Glutril and the maintenance of diabetic control with insulin. Glutril should be reintroduced when the patient has recovered from the infection or trauma.

If the patient requires an anaesthetic, it is recommended that the last dose the patient would normally receive prior to the procedure be omitted and/or glucose be given as soon as the patient recovers. If major surgery is undertaken, control should be maintained with insulin and/or intravenous glucose.

Side-effects: Glutril is well tolerated and, despite its potency, hypoglycaemic reactions are rare. Skin reactions and gastro-intestinal disturbances, such as nausea and vomiting, have been observed, but these occur in only a small proportion of patients. Transient depression of the platelet count has been observed.

Effects of overdosage and their treatment: If a hypoglycaemic reaction should occur, it may be rapidly controlled by the ingestion of appropriate carbohydrates. In the event of severe hypoglycaemia occurring, intravenous glucose or intramuscular glucagon should be given. Gastric lavage may be useful if performed soon after ingestion.

Pharmaceutical precautions Storage: Glutril Tablets should be stored in their original packing. The recommended maximum storage temperature for Glutril Tablets is 30°C.

Legal category POM.

Package quantities Glutril Tablets in blister packs of 100, each pack containing 10 strips each of 10 tablets.

Further information Glutril is rapidly and almost completely absorbed, with peak blood levels being attained two to four hours after administration. The plasma half-life is in the region of eight hours. Glutril is extensively metabolised following oral administration six metabolites having been identified. The metabolites are either inactive or possess hypoglycaemic properties which are considerably less than those of the parent compound.

Product licence number 0031/0059.

KONAKION®

Presentation White, sugar-coated tablets with 'ROCHE' printed in black across one face, containing 10 mg phytomenadione.

Ampoules containing 1 mg phytomenadione in 0.5 ml. The ampoule solution is clear to opalescent greenish-yellow.

Ampoules containing 10 mg phytomenadione in 1 ml. The ampoule solution is clear to opalescent greenish-yellow.

Uses Properties: Konakion is a synthetic preparation of vitamin K₁. The presence of vitamin K (i.e. vitamin K₁ itself or substances with vitamin K activity) is essential for the formation within the body of prothrombin, factor VII, factor IX and factor X. Lack of vitamin K leads to increased tendency to haemorrhage. When an antidote to an anticoagulant is necessary it is essential to use vitamin K₁ itself, as vitamin K analogues are much less effective.

Indications: Konakion is indicated in the treatment of haemorrhage or threatened haemorrhage associated

with a low blood level of prothrombin or factor VII. The main indications are: An antidote to anticoagulant drugs of the dicoumarol type. Prevention and treatment of neonatal haemorrhage.

Dosage and administration *Adults: As an antidote to anticoagulant drugs*

For severe haemorrhage: The anticoagulant should be withdrawn and an intravenous injection of Konakion given slowly in a dose of 10–20 mg (1 or 2 ampoules). The prothrombin level should be estimated three hours later, and if the response has been inadequate, the dose should be repeated. Not more than 40 mg of Konakion should be given intravenously in 24 hours.

Less severe haemorrhage: Konakion is given orally in doses of 10–20 mg (1–2 tablets). The prothrombin level is estimated 8–12 hours later and if the response has been inadequate, the dose should be repeated. Intramuscular injections of Konakion may also be given in doses of 10–20 mg (1 or 2 ampoules), repeated if necessary.

Lowering of prothrombin to dangerous level but no haemorrhage: A dose of 5–10 mg Konakion orally may be given to bring the prothrombin level back to within safe limits. In such instances it is not usually necessary to discontinue the anticoagulant.

Other indications: Adults: 10–20 mg.

Treatment of newborn infants: Prophylactic: 1 mg by intramuscular injection.

Therapeutic: 1 mg by intramuscular injection, repeated at eight-hourly intervals if necessary.

Children: If, on the recommendation of a physician, a children's dosage is required, then it is suggested that 5–10 mg be given.

Konakion Tablets are for oral administration and should be chewed or allowed to dissolve slowly in the mouth.

Konakion Ampoules are for intramuscular or intravenous injection.

Konakion Ampoule solution should not be diluted.

Contra-indications, warnings, etc *Precautions:* Intravenous injections of Konakion must be administered slowly and should be reserved for potentially fatal haemorrhage due to overdosage of anticoagulants of the coumarin and indanedione series. Not more than 40 mg should be given by intravenous injection during a period of 24 hours.

Side-effects: The too rapid intravenous administration of vitamin K₁ has caused reactions, including flushing of the face, sweating, a sense of chest constriction, cyanosis and peripheral vascular collapse.

It has been reported that repeated intramuscular injection of vitamin K₁ preparations, usually over prolonged periods in patients with hepatic disease, may very occasionally give rise to local cutaneous and subcutaneous changes.

Pharmaceutical precautions *Storage:* Konakion Ampoule solution should be protected from light; it should not be allowed to freeze. The recommended maximum storage temperature for Konakion Ampoules is 30°C.

Konakion Tablets should be stored in well-closed containers, protected from light.

Legal category Tablets P.
Ampoules POM.

Package quantities Konakion Tablets in packings of 25.

Konakion Ampoules 1 mg in 0.5 ml and 10 mg in 1 ml in packings of 10.

Further information Large doses of Konakion should be avoided if it is intended to continue with anticoagulant therapy. If haemorrhage is severe, a transfusion of fresh whole blood may be necessary whilst awaiting the effect of the vitamin K₁. Vitamin K₁ is not an antidote to heparin.

Ampoules 10 mg	0031/5077

LARODOPA*

Presentation Round, white tablets with 'ROCHE' in a hexagon imprinted on one face and two break bars on the other, containing 500 mg levodopa.

Uses *Properties:* Larodopa is an anti-Parkinsonian agent. Levodopa is the metabolic precursor of dopamine. The latter is severely depleted in the striatum, pallidum and substantia nigra of Parkinsonian patients and it is considered that administration of Larodopa raises the level of available dopamine in these centres.

Treatment with Larodopa gives worthwhile sustained relief in about two-thirds of these patients. Akinesia usually responds first, then rigidity and then tremor. Amelioration may be seen in other symptoms, including oculogyric crises. It may take six months or more before maximal improvement is achieved.

Indications: Parkinsonism – idiopathic, post-encephalitic. Previous neurosurgery is not a contra-indication to Larodopa.

Dosage and administration Dosage and administration are variable and no more than a guide can be given.

Adults: Hospitalised patients: Initially 0.25–1 g daily in up to five divided doses immediately after food. Dosage should be increased by 0.5–1 g every three to four days until adequate improvement results or intolerable side-effects appear. If severe side-effects appear, the dosage should be gradually decreased to the maximum tolerated. Patients in whom intolerance prevents the achievement of an effective drug level will usually benefit from a change of treatment to Madopar* (levodopa combined with a peripheral decarboxylase inhibitor).

General practice patients and out-patients: Initially 0.125 g twice daily immediately after food. After one week, the dose may be increased to 0.125 g four or five times daily. Thereafter dosage should be increased at weekly intervals by 0.375 g daily, the total daily dose being given in four or five divided doses. The response of individual patients varies and some patients may tolerate a more rapid rate of increase, e.g. by 0.25–0.5 g daily at intervals of three to four days.

Improvement is usually seen in two to three weeks with the normal dosage range being 2.5–8g daily, but further improvement may occur up to six months or even longer.

When the optimum daily dosage for any particular patient has been reached, it may need to be redistributed throughout the day to meet fluctuations in the individual's requirements. Most patients find a four or five times daily dosage scheme satisfactory; some obtain a smoother effect with two-hourly administration; others, who

develop akinetic crises at particular times of the day, learn by experience the daily dosage scheme most suited to their needs.

After a period at the maximum tolerated dosage level, side-effects may slowly develop, usually in the form of involuntary movements. These generally regress without loss of therapeutic effect if the dosage is slightly reduced.

Anticholinergic drugs should be continued during Larodopa therapy. As treatment with Larodopa proceeds and the therapeutic effect is found, the dosage of the anticholinergic drugs may need to be changed. Bromocriptine may be given with Larodopa.

Children: No dosage recommendations are made for the administration of Larodopa to children.

Larodopa Tablets are for oral administration.

Contra-indications, warnings, etc

Contra-indications: Larodopa is contra-indicated in narrow-angle glaucoma (it may be used in wide-angle glaucoma provided that the intra-ocular pressure remains under control); severe psychoneuroses or psychoses.

It should not be given in conjunction with monoamine oxidase inhibitors or within two weeks of their withdrawal.

Suspicion has arisen that levodopa may activate a malignant melanoma. Therefore Larodopa should not be used in persons who have a history of, or who may be suffering from, a malignant melanoma.

Precautions: Pyridoxine (vitamin B₆) which is often included in multivitamin preparations is known to block the effects of levodopa.

Drugs which interfere with central amine mechanisms, such as rauwolfia alkaloids (reserpine), phenothiazines, thioxanthenes, butyrophenones and amphetamines, should be avoided where possible. If, however, their administration is considered essential, extreme care should be exercised and a close watch kept for any signs of potentiation, antagonism or other interactions and for any unusual side-effects.

In the event of general anaesthesia being required, Larodopa therapy may be continued as long as the patient is able to take fluids and medication by mouth. If therapy is temporarily interrupted, the usual daily dosage may be administered as soon as the patient is able to take oral medication. Whenever therapy has been interrupted for longer periods, dosage should again be adjusted gradually; however, in many cases the patient can rapidly be returned to his previous therapeutic dosage.

When other drugs must be given in conjunction with Larodopa, the patient should be carefully observed for unusual side-effects or potentiating effects.

Care should be taken when using Larodopa in the following circumstances: in endocrine, renal, hepatic, pulmonary or cardiovascular disease; particularly where there is a history of myocardial infarction and in patients with peptic ulcer; where sympathomimetic drugs may be required, e.g. bronchial asthma; where antihypertensive drugs are being used. Periodic evaluation of hepatic, haemopoietic, renal and cardiovascular functions is advised.

Patients who improve on Larodopa therapy should be advised to resume normal activities gradually as rapid mobilisation may increase the risk of injury.

Animal experiments in different species have shown no evidence of deleterious effects of Larodopa on the physiology of reproduction or embryonic development. However, the established medical principle of prescribing medicaments in early pregnancy only when absolutely indicated should be observed.

Side-effects: Tolerance to Larodopa varies widely between patients and is often related to the rate of dosage increase. Post-encephalic Parkinsonian patients tolerate the drug less well. Side-effects, usually dose-related, occur at some time in most patients. During the initiation of therapy nausea and vomiting, anorexia, weakness and hypotension, which is usually postural (but a labile hypertension may rarely be seen), are most frequent. Nausea and vomiting may be minimised by administering Larodopa immediately after food, an anti-emetic, e.g. cyclizine hydrochloride 50 mg three times daily, may also be helpful.

Psychiatric disturbances are common in Parkinsonian patients including those being treated with levodopa. They include mild elation, anxiety, agitation, insomnia, depression and dementia.

Anxiety and insomnia may be treated with a benzodiazepine drug, e.g. Valium and Mogadon respectively. Depression may be treated with tricyclic anti-depressants and ECT may be administered if appropriate. Monoamine oxidase inhibitors must not be used.

Involuntary movements, commonly in the form of oral dyskinesias, often accompanied by 'paddling' foot movements, or of the choreoathetoid type, are common, particularly on long-term administration. They are usually dose-dependent and may disappear or become tolerable after dose reduction. With long-term administration, fluctuations in the therapeutic response may be encountered. They include 'freezing' episodes ('on-off') effect and end-of-dose deterioration. Patients may be helped by dosage reduction or by giving smaller and more frequent doses.

Transient rises in SGOT, SGPT and alkaline phosphatase values have been noted; serum uric acid and blood urea nitrogen levels are occasionally increased. On some occasions the urine passed during Larodopa treatment may be altered in colour; usually red-tinged, this will turn dark on standing. These changes are due to metabolites and are no cause for concern.

Effects of overdosage and their treatment: Symptoms of overdosage are qualitatively similar to the side-effects but may be of greater magnitude.

Treatment should include gastric lavage, general supportive measures, intravenous fluids and the maintenance of an adequate airway. Electrocardiographic monitoring should be instituted and the patient carefully observed for the possible development of arrhythmias. If necessary, anti-arrhythmic therapy should be given and other symptoms treated as they arise.

Pharmaceutical precautions *Storage:* Larodopa Tablets should be stored in well-closed containers, protected from light.

Legal category POM.

Package quantities Larodopa Tablets in packings of 200.

Further information Nil.

Product licence number 0031/5063.

LEXOTAN®

Presentation Pink, hexagonal biconvex tablets having L3 imprinted on one face and a single break bar on the other, containing 3 mg bromazepam.

Uses *Properties:* Lexotan is a pyridylbenzodiazepine compound with anxiolytic properties.

Indications: Lexotan is indicated for the short-term treatment of anxiety and associated symptoms such as tension and agitation.

Dosage and administration Adults: It is important that the dosage of Lexotan be determined on an individual basis. The usual doses are: Mild to moderate anxiety 3–6 mg three times daily; severe anxiety states 6–12 mg three times daily.

Some patients may be more sensitive to the effects of Lexotan and may respond to 1.5 mg three times daily.

In exceptionally severe anxiety states, in hospitalised patients, up to 60 mg daily may be given in divided doses.

Maximum daily dosage 60 mg.

Elderly: Elderly patients are more sensitive to the actions of Lexotan. The safety of Lexotan for use in the elderly has not been established and therefore its use should be avoided.

Children: Lexotan is not for paediatric use.

Lexotan tablets are for oral administration.

Contra-indications, warnings, etc

Contra-indications: Patients with known sensitivity to benzodiazepines; acute pulmonary insufficiency; respiratory depression.

Precautions: In patients with chronic pulmonary insufficiency, and in patients with chronic renal or hepatic disease, dosage may need to be reduced. The use of Lexotan during pregnancy should be avoided.

The administration of high doses or prolonged administration of low doses of benzodiazepines in the last trimester of pregnancy or during labour has been reported to produce irregularities in the foetal heart, and hypotonia, poor sucking and hypothermia in the neonate.

Benzodiazepines have been detected in breast milk. If possible, the use of Lexotan should be avoided during lactation.

If Lexotan is combined with centrally-acting drugs such as neuroleptics, tranquillisers, antidepressants, hypnotics, analgesics and anaesthetics, the sedative effects may be intensified.

Patients should be advised that, like all medicaments of this type, Lexotan may modify patients' performance at skilled tasks (driving, operating machinery, etc.) to a varying degree depending upon dosage and individual susceptibility. Patients should further be advised that alcohol may intensify any impairment, and should therefore be avoided during treatment.

The dependence potential of the benzodiazepines is low but this increases when high doses are used, especially when given over long periods. This is particularly so in patients with a history of alcoholism or drug abuse or in patients with marked personality disorders. Regular monitoring in such patients is essential, routine repeat prescriptions should be avoided and treatment should be withdrawn gradually. Symptoms such as depression, nervousness, rebound insomnia, irritability, sweating and diarrhoea have been reported following abrupt cessation of treatment with normal therapeutic doses. In rare instances, withdrawal following excessive dosages may produce confusional states, psychotic manifestations and convulsions.

Abnormal psychological reactions to benzodiazepines have been reported. Rare behavioural effects include paradoxical aggressive outbursts, excitement, confusion, and the uncovering of depression with suicidal tendencies.

Side-effects: Common adverse effects include drowsiness, sedation, unsteadiness and ataxia; these are dose-related and may persist into the following day, even after a single dose. Drowsiness may be a particular problem when Lexotan is used in higher dosage in some patients, especially if they are unused to this form of therapy. Sensitivity to central depressant drugs usually increases with age, and older subjects, particularly those with organic brain changes, may be more liable to develop confusion; in these patients the dosage of Lexotan should be kept to a minimum.

Other adverse effects are rare and include headache, vertigo, hypotension, gastro-intestinal upsets, skin rashes, visual disturbances, changes in libido, and urinary retention. Isolated cases of blood dyscrasias and jaundice have also been reported.

Treatment of overdosage: When taken alone in overdosage Lexotan presents few problems in management. Signs may include drowsiness, ataxia and dysarthria, with coma in severe cases. Treatment is symptomatic. Gastric lavage is useful only if performed soon after ingestion. There is no specific antidote to Lexotan.

When taken with centrally-acting drugs, especially alcohol, the effects of overdosage are likely to be more severe and, in the absence of supportive measures, may prove fatal.

Pharmaceutical precautions Storage: Lexotan tablets should be stored in well-closed containers.

Legal category POM.

Package quantities Lexotan tablets 3 mg in packings of 100 and 500.

Further information Lexotan is rapidly absorbed from the gastro-intestinal tract. The mean half-life for elimination of Lexotan in man is about 16 hours. Metabolites of Lexotan do not contribute significantly to the effects of the drug.

Clinically, the anxiolytic effect of bromazepam 3 mg is generally equivalent to that of diazepam 5 mg.

Product licence number 0031/0128.

LORFAN®

Presentation Ampoules containing 1 mg levallorphan tartrate in 1 ml. The ampoule solution is colourless.

Uses Properties: Levallorphan is strongly antagonistic to some of the characteristic effects of morphine and of similar compounds such as Dromoran® Roche and pethidine. In small doses levallorphan counteracts the respiratory depression caused by morphine-like drugs without appreciably altering their analgesic effect. In large doses the analgesic effect is also antagonised. Levallorphan itself has little or no analgesic activity, nor does it behave in other respects like morphine. There is evidence that it does not cause addiction.

Indications: Narcotic-induced respiratory depression.

Dosage and administration Adults: Anaesthesia: To restore respiration which has been depressed by the administration of morphine-like drugs, 0.5–1 mg intravenously, repeated if necessary at intervals of three to five minutes until normal respiration is achieved.

To prevent respiratory depression, Lorfan is given either before or with the analgesic. Lorfan 0.3–0.5 mg for each 15 mg morphine. Lorfan 1–1.5 mg for each 100 mg

pethidine. Lofran 0.2–0.3 mg for each 2 mg Dromoran* Roche.

Obstetrics: To prevent respiratory depression in the infant, Lofran can be administered intramuscularly to the mother together with each dose of the analgesic. Clinical experience has been mainly with Lofran and pethidine. Dose, Lofran 1.25 mg with each 100 mg pethidine.

To restore respiration in infants with respiratory depression following the administration of pethidine to the mother, Lofran 0.05–0.25 mg may be injected into the umbilical vein immediately after delivery.

Treatment of overdosage of a narcotic: Lofran 1–2 mg intravenously. If adequate spontaneous respiration is not obtained within 5–10 minutes, one-half the initial dose may be repeated. It may be necessary to repeat the dose again some hours later, if signs of narcotic intoxication recur.

Lofran Ampoules are for intravenous injection.

Lofran Ampoule solution may be diluted with Water for Injection.

Maintenance of stability cannot be guaranteed when Lofran Ampoule solution is diluted.

Contra-indications, warnings, etc Precautions: With Lofran, as with other drugs acting on the central nervous system, patients should be instructed to avoid alcohol while under treatment, since the individual response cannot be foreseen. Like all medicaments of this type, Lofran may modify patients' reactions (driving ability, operation of machinery, etc) to a varying extent, depending on dosage and individual susceptibility.

Side-effects: Lofran used alone may produce some respiratory depression.

Effects of overdosage and their treatment: Symptoms of overdosage may include drowsiness, coma, sweating, restlessness, bradycardia, hypotension and miosis. When given alone Lofran may cause psychotic disturbances and respiratory depression.

The airway should be maintained and artificial respiration and oxygen administered. Use of anaesthetics may be of some aid but should not be depended on to maintain respiration.

Pharmaceutical precautions *Storage:* Lofran Ampoules should be protected from light.

Legal category POM.

Package quantities Lofran Ampoules in packings of 10.

Further information Lofran plus pethidine in the proportions of 1.25 mg Lofran to 100 mg pethidine is available as Pethilofran*. See separate data sheet.

Product licence number 0031/5031.

MADOPAR*

Presentation Madapar 62.5 Capsules with blue cap and grey body with 'ROCHE' printed in black on both cap and body, containing 50 mg levodopa and 14.25 mg benserazide hydrochloride (equivalent to 12.5 mg of the base).

Madapar 125 Capsules with blue cap and pink body with 'ROCHE' printed in black on both cap and body, containing 100 mg levodopa and 28.5 mg benserazide hydrochloride (equivalent to 25 mg of the base).

Madapar 250 Capsules with blue cap and caramel body with 'ROCHE' printed in black on both cap and

body, containing 200 mg levodopa and 57 mg benserazide hydrochloride (equivalent to 50 mg of the base).

Uses Properties: Madapar is an anti-Parkinsonian agent. Levodopa is the metabolic precursor of dopamine. The latter is severely depleted in the striatum, pallidum and substantia nigra of Parkinsonian patients and it is considered that administration of levodopa raises the level of available dopamine in these centres. However, conversion of levodopa into dopamine by the enzyme dopa decarboxylase also takes place in extra-cerebral tissues. As a consequence the full therapeutic effect may not be obtained and side-effects occur.

Administration of a peripheral decarboxylase inhibitor, which blocks the extracerebral decarboxylation of levodopa, in conjunction with levodopa has significant advantages: these include reduced gastro-intestinal side-effects, a more rapid response at the initiation of therapy and a simpler dosage regimen.

Madapar is a combination of levodopa and benserazide in the ratio of 4:1 which in clinical trials has been shown to be the most satisfactory.

Indications: Parkinsonism – idiopathic, post-encephalitic. Previous neurosurgery is not a contra-indication to Madapar.

Dosage and administration Dosage and administration are variable and no more than a guide can be given.

Patients not previously treated with levodopa: The initial recommended dose is 1 capsule of Madapar 125 twice daily. This dose may be increased by 1 capsule per day every third or fourth day until a full therapeutic effect is obtained, or side-effects supervene. Individual patient response varies, and some patients may only tolerate a slower rate of increase, e.g. 1 capsule of Madapar 125 at weekly intervals.

The effective dose usually lies within the range of 4–8 capsules of Madapar 125 (2–4 capsules of Madapar 250) daily in divided doses, most patients requiring no more than 6 capsules of Madapar 125 daily.

Madapar 62.5 capsules may be used to facilitate adjustment of dosage to the needs of the individual patient. In some elderly patients, it may suffice to initiate treatment with one capsule of Madapar 62.5 once or twice daily, increasing by one capsule every third or fourth day. Patients who experience fluctuations in response may also be helped by dividing the dosage into smaller, more frequent doses with the aid of Madapar 62.5 capsules.

Optimal improvement is usually seen in one to three weeks, but the full therapeutic effect of Madapar may not be apparent for some time. It is advisable, therefore, to allow several weeks to elapse before contemplating dosage increments above the average dose range. If satisfactory improvement is still not achieved, the dose of Madapar may be increased, but with caution. It is rarely necessary to give more than 10 capsules of Madapar 125 (5 capsules of Madapar 250) per day.

Treatment should be continued for at least six months before failure is concluded from the absence of a clinical response.

Madapar 250 Capsules are only for maintenance therapy once the optimal dosage has been determined using Madapar 125 Capsules.

Patients previously treated with levodopa: The following procedure is recommended:

Levodopa alone should be discontinued and Madapar started on the following day. The patient should be initiated on a total of one less Madapar 125 Capsule

daily than the total number of 500 mg levodopa tablets or capsules previously taken (for example, if the patient had previously taken 2 g levodopa daily, then he should start on 3 capsules Madopar 125 daily on the following day).

Observe the patient for one week and then, if necessary, increase the dosage in the manner described for new patients.

Patients previously treated with other levodopa/decarboxylase inhibitor combinations: Previous therapy should be withdrawn for 12 hours. Madopar therapy should then be started with one capsule of Madopar 125 twice daily. This dose may then be increased in the manner described for patients not previously treated with levodopa.

Other anti-Parkinsonian drugs, e.g. anticholinergics, should be continued during Madopar therapy. As treatment with Madopar proceeds and the therapeutic effect becomes apparent, the dosage of the other drugs may need to be changed. Bromocriptine may be given with Madopar.

Children: Not to be given to patients under 25 years of age; therefore, no dosage recommendations are made for the administration of Madopar to children.

Madopar Capsules are for oral administration.

Madopar Capsules must always be swallowed whole. They should be taken with, or immediately after, meals.

Contra-indications, warnings, etc

Contra-indications: Madopar is contra-indicated in narrow-angle glaucoma (it may be used in wide angle glaucoma provided that the intra-ocular pressure remains under control); severe psychoneuroses or psychoses.

It should not be given in conjunction with monoamine oxidase inhibitors, or within two weeks of their withdrawal.

It should not be given to patients under 25 years of age.

It should not be given to pregnant women; should a woman become pregnant, she should immediately discontinue therapy.

Suspicion has arisen that levodopa may activate a malignant melanoma. Therefore Madopar should not be used in persons who have a history of, or who may be suffering from, a malignant melanoma.

Precautions: Drugs which interfere with central amine mechanisms, such as rauwolfia alkaloids (reserpine), phenothiazines, thioxanthenes, butyrophenones and amphetamines, should be avoided where possible. If, however, their administration is considered essential, extreme care should be exercised and a close watch kept for any signs of potentiation, antagonism or other interactions and for any unusual side-effects.

In the event of general anaesthesia being required, Madopar therapy may be continued as long as the patient is able to take fluids and medication by mouth. If therapy is temporarily interrupted, the usual daily dosage may be administered as soon as the patient is able to take oral medication. Whenever therapy has been interrupted for longer periods, dosage should again be adjusted gradually; however, in many cases the patient can rapidly be returned to his previous therapeutic dosage.

When other drugs must be given in conjunction with Madopar, the patient should be carefully observed for unusual side-effects or potentiating effects. Pyridoxine (vitamin B₆) may be given with Madopar, but not with levodopa alone.

Care should be taken when using Madopar in the

following circumstances: in endocrine, renal, pulmonary or cardiovascular disease; particularly where there is a history of myocardial infarction or arrhythmia, hepatic disorder, peptic ulcer or osteoporosis; where sympathomimetic drugs may be required, e.g. bronchial asthma; where antihypertensive drugs are being used.

Periodic evaluation of hepatic, haemopoietic, renal and cardiovascular functions is advised.

Patients who improve on Madopar therapy should be advised to resume normal activities gradually as rapid mobilisation may increase the risk of injury.

Side-effects: Tolerance to Madopar varies widely between patients and is often related to the rate of dosage increases. Side-effects such as nausea and vomiting, which are frequently observed during the initial stages of levodopa therapy, are much less common in patients treated with Madopar. Also, cardiovascular disturbances such as arrhythmias and orthostatic hypotension may occur, but are less frequent than in patients treated with levodopa alone.

Psychiatric disturbances are common in Parkinsonian patients including those being treated with levodopa. They include mild elation, anxiety, agitation, insomnia, depression and dementia.

Anxiety and insomnia may be treated with a benzodiazepine drug, e.g. Valium and Mogadon respectively. Depression may be treated with tricyclic anti-depressants and ECT may be administered if appropriate. Monoamine oxidase inhibitors must not be used.

Involuntary movements, commonly in the form of oral dyskinesias, often accompanied by 'paddling' foot movements, or of the choreoathetoid type, are common, particularly on long-term administration. They are usually dose-dependent and may disappear or become tolerable after dose reduction.

With long-term administration, fluctuations in the therapeutic response may be encountered. They include 'freezing' episodes ('on-off' effect) and end-of-dose deterioration. Patients may be helped by dosage reduction or by giving smaller and more frequent doses.

Transient rises in SGOT, SGPT and alkaline phosphatase values have been noted; serum uric acid and blood urea nitrogen levels are occasionally increased.

Effects of overdosage and their treatment: Symptoms of overdosage are qualitatively similar to the side effects but may be of greater magnitude.

Treatment should include gastric lavage, general supportive measures, intravenous fluids and the maintenance of an adequate airway. Electrocardiographic monitoring should be instituted and the patient carefully observed for the possible development of arrhythmias. If necessary, anti-arrhythmic therapy should be given and other symptoms treated as they arise.

Pharmaceutical precautions *Storage:* Madopar capsules should be protected from moisture.

Legal category POM.

Package quantities Madopar 62.5 Capsules containing 50 mg levodopa and 12.5 mg benserazide in bottles of 100.

Madopar 125 Capsules containing 100 mg levodopa and 25 mg benserazide in bottles of 100.

Madopar 250 Capsules containing 200 mg levodopa and 50 mg benserazide in bottles of 100.

Further information Nil.

MADRIBON*

Presentation Round, white tablets with 'Roche' imprinted on one face with two break bars on the other, containing 500 mg sulphadimethoxine.

Uses Properties: Madribon is a long-acting sulphonamide. Therapeutic blood levels are maintained for at least 24 hours after each dose; consequently, a single daily dose is sufficient.

Madribon differs from most sulphonamides in that only small amounts are conjugated in the form of the acetyl derivative, whereas the greater part is conjugated as glucuronide, and excreted in the urine as such. This glucuronide, unlike the acetyl derivatives of most sulphonamides, is highly soluble and, as a result, the risk of renal complications with Madribon is minimal.

Indications: Madribon is indicated in all infections due to organisms which are sulphonamide-sensitive. Trials have shown Madribon to be very effective in the treatment of: bronchitis; ear, nose and throat infections; pneumonia; infections of the urinary tract; bacillary dysentery; skin and soft tissue infections; prophylactic treatment of secondary infections.

Dosage and administration

	<i>Tablets</i>	
	<i>Initial</i>	<i>Maintenance 24-hourly</i>
Adults and older children	4	2
Children		
9-14 years	3	1½
5-8 years	2	1
2-4 years	1	½

For mild infections half the above doses are given. For long-term prophylaxis half the maintenance dose is given daily.

Madribon Tablets are for oral administration.

Contra-indications, warnings, etc

Contra-indications: Like all other sulphonamides, Madribon is contra-indicated in premature and new-born infants during the first weeks of life and in pregnant women during the week before term.

Madribon should not be given to patients with a history of sulphonamide sensitivity. As with many other compounds, rare, but sometimes serious, allergo-toxic skin conditions have been reported in connection with long-acting sulphonamides. Although no direct evidence exists to associate Madribon as the causative agent of such conditions, if a rash occurs during therapy, treatment should be immediately discontinued.

Side-effects: Clinical experience has shown Madribon to be exceptionally free from serious side-effects although, occasionally, patients may experience the reactions common to sulphonamides, including nausea, vomiting, glossitis and skin rashes. Leucopenia may rarely occur over long periods of treatment, hence regular blood counts are recommended during long-term treatment.

Effects of overdosage and their treatment: Symptoms of overdosage may include vomiting, mental and visual disturbances, petechiae, purpura and jaundice. In severe cases, haematuria, crystalluria and anuria may occur, but this is less likely with Madribon than with other sulphonamides since it is excreted mainly as a soluble glucuronide.

Treatment is symptomatic; gastric lavage may be useful. An adequate fluid intake should be maintained and the urine made alkaline. Hypersensitivity reactions may require treatment with steroids.

Pharmaceutical precautions Storage: Madribon Tablets should be stored in well-closed containers, protected from light.

Legal category POM.

Package quantities Madribon Tablets in packings of 50.

Further information Nil.

Product licence number 0031/5032.

MARPLAN*

Presentation Round, pink tablets with 'ROCHE' imprinted across one face with a single break bar on the other, containing 10 mg isocarboxazid.

Uses Properties: Marplan is a potent antidepressant; it is a monoamine oxidase inhibitor, effective in small doses. Its action is thought to be related to its effect on physiological amines such as serotonin and noradrenaline, and this effect is cumulative and persistent.

Indications: Depressive states.

Dosage and administration Adults: A daily dose of 30 mg should be given until the optimal effect is obtained. The maximal effect is only observed after a period varying from one to four weeks. Once this takes place, the dose should be reduced to the lowest possible amount sufficient to maintain the improvement. Clinical experience has shown this to be 10 to 20 mg daily.

Children: No dosage recommendations are made for the administration of Marplan to children.

Marplan Tablets are for oral administration.

Contra-indications, warnings, etc Precautions: Some monoamine oxidase inhibitors have occasionally caused jaundice in patients, therefore frequent examination of the patient should be carried out. If there is any evidence of a toxic reaction, the drug should be withdrawn immediately. The drug should be used cautiously in patients with impaired renal function, to prevent accumulation taking place.

Monoamine oxidase inhibitors potentiate a number of drugs and foods. These include pethidine and other narcotics and depressants, stimulants (including amphetamines), sympathomimetics and vasopressors, local anaesthetics, ganglion-blocking agents, imipramine and amitriptyline derivatives, levodopa, hypotensive compounds, including reserpine, diuretics, and some tranquillisers. Patients should be warned to avoid foodstuffs and beverages with a high amine content, including: cheese, hydrolysed protein extracts, Chianti wines and other foods which are not fresh and are fermented, 'hung', 'matured' or otherwise subject to protein degradation before consumption. As Marplan is a monoamine oxidase inhibitor due consideration should be given to these observations.

The effects of monoamine oxidase inhibitors may persist for up to two weeks and, therefore, an interval of one to two weeks should be allowed after treatment with Marplan before the administration of antidepressants with a different mode of action. If dentistry, surgery or a change in treatment of a patient becomes necessary during that time, the fact that monoamine oxidase inhibitors have been prescribed previously should be known and taken into account. On the other hand, Marplan may be given immediately following treatment with antidepressants having a different mode of action.

In restless, agitated patients, Marplan may precipitate states of excessive excitement.

With Marplan, as with other drugs acting on the central nervous system, patients should be instructed to avoid alcohol while under treatment, since the individual response cannot be foreseen. Like all medicaments of this type, Marplan may modify patients' reactions (driving ability, operation of machinery, etc) to a varying extent, depending on dosage and individual susceptibility.

The established medical principle of prescribing medicaments in early pregnancy only when absolutely indicated should be observed.

Side-effects: In general, Marplan is well tolerated by the majority of patients. If side-effects occur they are those common to the group of monoamine oxidase inhibitors and include orthostatic hypotension, dizziness, constipation, overactivity, insomnia, dryness of the mouth, and blurred vision. Peripheral oedema and rashes have occasionally been observed.

Effects of overdose and their treatment: The primary symptoms of overdose include dizziness, ataxia and irritability. In acute cases, hypotension or hypertension, tachycardia, pyrexia, psychotic manifestations, convulsions, respiratory depression and coma may occur and continue for 8–14 days before recovery.

Gastric lavage should be performed soon after ingestion and intensive supportive therapy carried out. Sympathomimetic agents should not be given to treat hypotension, but plasma expanders may be used in severe cases. Hypertensive crises may be treated by pentolinium or phentolamine, severe shock with hydrocortisone. Haemodialysis is of value in very severe cases.

Pharmaceutical precautions *Storage:* Marplan Tablets should be stored in well-closed containers.

The recommended maximum storage temperature is 25°C.

Legal category POM.

Package quantities Marplan Tablets in packings of 50.

Further information Nil.

Product licence number 0031/5080.

MARSILID*

Presentation Round, light orange tablets with 'm' imprinted on one face and a single break bar on the other, containing 39.1 mg iproniazid phosphate (equivalent to 25 mg iproniazid).

Round, pale yellow tablets with 'm' imprinted on one face and a double break bar on the other, containing 78.2 mg iproniazid phosphate (equivalent to 50 mg iproniazid).

Uses *Properties:* Mersilid is a potent antidepressant: it is a monoamine oxidase inhibitor. Its action is thought to be related to its effects on physiological amines such as serotonin and noradrenaline, and this effect is cumulative and persistent.

Indications: Treatment of the symptoms of severe depressive illness.

Dosage and administration *Adults:* A single daily dose of 100 to 150 mg should be given, normally in the morning, until improvement is observed. Thereafter the dose may be reduced gradually until the patient is taking a maintenance dose as small as 25 or 50 mg daily.

Children: Mersilid is not indicated for paediatric use. Mersilid tablets are for oral administration.

Contra-indications, warnings, etc

Contra-indications: Mersilid is contra-indicated in patients with any impairment of hepatic function, cerebrovascular disorders or severe cardiovascular disease, and in those with actual or suspected phaeochromocytoma.

Like other monoamine oxidase inhibitors, Mersilid potentiates the action of a number of drugs and foods. Patients being treated with a monoamine oxidase inhibitor should not receive indirectly-acting sympathomimetic agents, such as amphetamines, metaraminol, fenfluramine or similar anorectic agents, ephedrine or phenylpropanolamine (contained in many proprietary 'cold-cure' medications), dopamine or levodopa. Patients should also be warned to avoid foodstuffs and beverages with a high tyramine content: matured cheeses (including processed cheeses), hydrolysed yeast or meat extracts, heavy red wines such as Chianti, and other foods which are not fresh and are fermented, pickled, 'hung', 'matured' or otherwise subject to protein degradation before consumption. Broad bean pods (which contain levodopa) and banana skins may also present a hazard.

In extreme cases interactions may result in severe hypertensive episodes. Mersilid should therefore be discontinued immediately upon the occurrence of palpitations or frequent headaches.

Circulatory collapse, respiratory depression, central excitation and coma have been reported from the combination of monoamine oxidase inhibitors and pethidine. If a narcotic analgesic is required in a patient receiving Mersilid, a drug other than pethidine should be used, initially in a small dose, which should be increased cautiously.

Mersilid should not be administered together with, or immediately following, other monoamine oxidase inhibitors or tricyclic antidepressants. An interval of two weeks should be allowed after treatment with Mersilid before the administration of another antidepressant or any other drug which may interact.

Mersilid should be discontinued for at least two weeks prior to elective surgery requiring general anaesthesia.

Precautions: The use of Mersilid should be restricted to patients who have failed to respond to other forms of treatment and, in the first instance, should be initiated in hospital.

Concurrent administration of Mersilid with other central nervous system depressants (especially barbiturates and phenothiazines), stimulants, local anaesthetics, ganglion-blocking agents and other hypotensives (including methyldopa and reserpine), diuretics, vasopressors, anticholinergic drugs and hypoglycaemic agents lead to potentiation of their effects. This should be borne in mind if dentistry, surgery or a change in treatment of

a patient becomes necessary during treatment with Marsilid.

All patients taking Marsilid should be warned against self-medication with proprietary 'cold-cure' preparations (including nasal decongestants) and advised of the dietary restrictions listed under 'Contra-indications'.

With Marsilid, as with other drugs acting on the central nervous system, patients should be instructed to avoid alcohol while under treatment, since the individual response cannot be foreseen. Like all medicaments of this type, Marsilid may modify patients' reactions (driving ability, operation of machinery, etc) to a varying extent, depending on dosage and individual susceptibility.

Hepatic complications and jaundice are known to have occurred during treatment with Marsilid, therefore regular monitoring of liver function should be carried out in patients who receive the drug. If there is any evidence of a hepatotoxic reaction, Marsilid should be withdrawn immediately.

The drug should be used cautiously in patients with impaired renal function, to prevent accumulation taking place, and also in the elderly or debilitated and those with cardiovascular disease, diabetes or blood dyscrasias.

In restless or agitated patients, Marsilid may precipitate states of excessive excitement. Higher doses of Marsilid may precipitate epileptiform fits, especially in patients with a history of epilepsy.

Marsilid should not be used in pregnancy unless there are compelling reasons to do so. No information on transfer of the drug into breast milk is available.

Side-effects: Side-effects caused by Marsilid are those common to the group of monoamine oxidase inhibitors. The most frequently reported have been orthostatic hypotension, associated in some patients with disturbances in cardiac rhythm, peripheral oedema, complaints of dizziness, dryness of the mouth, nausea and vomiting, constipation, difficulty in micturition, impairment of erection and ejaculation, blurred vision, insomnia, drowsiness, headaches, weakness and fatigue. These side-effects can usually be controlled by dosage reduction. There have been less frequent reports of sweating, paraesthesiae, hyperreflexia, agitation, overactivity, muscle tremor, confusion and other behavioural changes, and skin rashes. Peripheral neuritis has sometimes been observed and can be prevented by giving pyridoxine (vitamin B6) to patients on high doses of Marsilid. Response to Marsilid may be accompanied by increased appetite and weight gain.

Treatment of overdosage: The primary symptoms of overdosage include dizziness, ataxia and irritability. In acute cases, hypotension or hypertension, tachycardia, pyrexia, psychotic manifestations, convulsions, respiratory depression and coma may occur and continue for eight to fourteen days before recovery.

Gastric lavage should be performed soon after ingestion and intensive supportive therapy carried out.

Sympathomimetic agents should not be given to treat hypotension but plasma expanders may be used in severe cases. Hypertensive crises may be treated by pentolinium or phentolamine, severe shock with hydrocortisone. Diazepam may be given to control convulsions or severe excitement. Dialysis is of value in eliminating the drug in severe cases.

Pharmaceutical precautions *Storage:* Marsilid Tablets should be stored in well-closed containers. The recommended maximum storage temperature is 30°C.

Legal category POM.

Package quantities Marsilid Tablets 25 mg in packings of 50.

Marsilid Tablets 50 mg in packings of 100.

MESTINON*

Presentation Round, white tablets with 'ROCHE' imprinted across one face with two break bars on the other, containing 60 mg pyridostigmine bromide.

Ampoules containing 1 mg pyridostigmine bromide in 1 ml. The ampoule solution is colourless to faintly yellow.

Uses *Properties:* Mestinon is an antagonist to cholinesterase, the enzyme which normally destroys acetylcholine. The action of Mestinon can briefly be described, therefore, as the potentiation of naturally occurring acetylcholine. Mestinon has a more prolonged action than Prostigmin* (neostigmine), although it is somewhat slower to take effect; because it has a weaker 'muscarinic' action than Prostigmin, it is usually much better tolerated by myasthenic patients in whom the longer action is also an advantage.

Indications: Myasthenia gravis; intestinal atony; paralytic ileus; post-operative distension; heartburn of pregnancy.

Dosage and administration

Myasthenia gravis: Adults: A daily dose of 5–20 tablets by mouth or 2–5 mg by injection is commonly given, but doses higher than these may be needed by some patients. The daily doses should be spread over the day and taken at times when they are most required.

Myasthenia gravis: Children: If, on the recommendation of a physician, a children's dosage is required then the following is given as a guide:

Newborn infants: Usually 0.2–0.4 mg by injection or 5–10 mg orally every four hours.

Older children: Trial dose of 10 mg orally, increasing by 5 mg increments until a satisfactory result obtains.

Other indications: The usual adult dose is 1–4 tablets by mouth or 1–5 mg by subcutaneous or intramuscular injection; the frequency of dosage may be varied according to the needs of the patient.

Children: If, on the recommendation of a physician, a children's dosage is required, then 15–60 mg by mouth or 0.25–1 mg by injection may be given.

Mestinon Tablets are for oral administration.

Mestinon Ampoules are for intramuscular, intravenous or subcutaneous injection.

Mestinon Ampoule solution may be diluted with Water for Injection.

Maintenance of stability cannot be guaranteed when Mestinon Ampoule solution is diluted.

Contra-indications, warnings, etc *Precautions:* Care should be taken in administering Mestinon to patients with bronchial asthma.

Side-effects: These may include nausea and vomiting, increased salivation, diarrhoea and abdominal cramps.

Effects of overdosage and their treatment: Signs of overdosage due to muscarinic effects may include abdominal cramps, increased peristalsis, diarrhoea, nausea and vomiting, increased bronchial secretions, salivation, diaphoresis and miosis. Nicotinic effects consist of muscular cramps, fasciculations and general weakness. Bradycardia and hypotension may also occur. Artificial respiration should be instituted if respiratory depression is severe. Atropine sulphate 1–2 mg intravenously is an antidote to the muscarinic effects.

Pharmaceutical precautions *Storage:* Recommended maximum storage temperature for Ampoules and Tablets is 25°C. Mestison Tablets and Ampoules should be protected from light. Mestison Tablets should be protected from moisture.

Legal category POM.

Package quantities Mestison Tablets in packings of 100.

Mestison Ampoules in packings of 10.

Further information Nil.

Ampoules 0031/5037.

MOGADON®

Presentation Round, white tablets with 'ROCHE' and two semi-circles imprinted on one face with a single break bar on the other, containing 5 mg nitrazepam.

Capsules with black cap and translucent purple body with 'ROCHE 5' printed in red along both cap and body, containing 5 mg nitrazepam.

Uses Properties: Mogadon rapidly induces sleep lasting six to eight hours, by shielding from sensory and emotional stimuli those centres in the brain responsible for maintaining wakefulness. Unlike non-benzodiazepine hypnotics, Mogadon does not force the onset of sleep by a generalised depression of all the brain structures but induces sleep similar to the normal pattern. The sleeper may be readily aroused and yet will be able to return to sleep again without difficulty.

Indications: Sleep disturbances due to anxiety, worry, tension, stress, depression, irritability, overwork and conflict.

Mogadon is particularly valuable in the treatment of sleep disturbances of the middle-aged patient; insomnia in the elderly patient where the use of barbiturates tends to cause confusion; organic sleep disturbances when administered in conjunction with specific therapy.

Dosage and administration *Adults:* 5 mg before retiring. This average dose may if necessary be increased up to 10 mg for out-patients and up to 20 mg for in-patients.

Elderly patients: 2.5–5 mg.

The tablets can be chewed, swallowed whole or taken in liquid.

Children: If, on the recommendation of a physician, a child's dosage is required, it is suggested that 2.5–5 mg may be given.

Mogadon Tablets and Capsules are for oral administration.

Contra-indications, warnings, etc *Precautions:* Potentiation of alcohol by Mogadon has not been demonstrated, but, as with all other drugs acting on the central nervous system, patients should be instructed to avoid taking alcohol while under treatment with Mogadon, since the individual response cannot be foreseen. Like all medicaments of this type, Mogadon may modify patients' reactions (driving ability, operation of machinery, etc) to a varying extent, depending on dosage and individual susceptibility. The rate of metabolism of Mogadon will normally ensure that such effects do not persist to the morning.

The use of high doses of benzodiazepines, especially over prolonged periods, may sometimes lead to dependence, particularly in patients with a history of alcoholism or drug abuse. Treatment in these cases should be withdrawn gradually.

Results obtained in trials with several generations of mice, rats, rabbits and dogs indicate that no danger of teratogenic effects need be expected from therapeutic doses of Mogadon. Nevertheless, the established medical principle of prescribing medicaments in early pregnancy only when absolutely indicated should be observed.

As with many other medications, a reduced dosage may suffice in the elderly. Therefore, treatment should be initiated with a 2.5 mg dose until the response can be judged. Similar care should be taken in patients with respiratory depression.

Side-effects: Mogadon is well tolerated. Minor side-effects such as fatigue and morning drowsiness may occasionally occur. Prolonged and extensive clinical and laboratory investigations have revealed no significant changes in the blood picture or liver function.

Effects of overdosage and their treatment: Reported experience of inadvertent or deliberate overdosage indicates that this presents virtually no problem. Doses of up to approximately 550 mg (110 times the usual dose) have produced no long-term ill-effects. The primary symptoms of overdosage are drowsiness, dizziness, ataxia and slurred speech.

Treatment is symptomatic, but gastric lavage may be useful if performed soon after ingestion.

Pharmaceutical precautions *Storage:* Recommended maximum storage temperature for Mogadon Tablets and Capsules is 30°C. Mogadon Tablets and Capsules should be protected from light.

Legal category POM.

Package quantities Mogadon Tablets 5 mg in packings of 100 and 500.

Mogadon Capsules 5 mg in packings of 100 and 500.

Further information Nil.

Capsules 5 mg 0031/0083.

NATULAN®

Presentation Capsules with opaque pale yellow cap and body with 'ROCHE' printed in red-brown along both

cap and body, containing 58.3 mg procarbazine hydrochloride (equivalent to 50 mg of procarbazine).

Uses Properties: Natulan, a methylhydrazine derivative, is a cytostatic agent. It is effective in patients who have become resistant to radiation therapy and other cytostatic agents.

Indications: The main indication is Hodgkin's disease (lymphadenoma).

Natulan may also be useful in other advanced lymphomata and a variety of solid tumours which have proved resistant to other forms of therapy.

Dosage and administration *In combination chemotherapeutic regimens:* Natulan is usually administered concomitantly with other appropriate cytostatic drugs in repeated four- to six-weekly cycles. In most such combination chemotherapy regimens currently in use (e.g. the so-called MOPP schedule with mustine, vincristine and prednisone) Natulan is given daily on the first 10–14 days of each cycle in a dosage of 100 mg per sq. metre of body surface (to nearest 50 mg).

As sole therapeutic agent: Adults: Treatment should begin with small doses which are increased gradually up to a maximum daily dose of 250 or 300 mg divided as evenly as possible throughout the day.

Initial dosage scheme

1st day	50 mg	4th day	200 mg
2nd day	100 mg	5th day	250 mg
3rd day	150 mg	6th day et seq.	250–300 mg

Further procedure: Treatment should be continued with 250 or 300 mg daily until the greatest possible remission has been obtained, after which a maintenance dose is given.

Maintenance dose: 50–150 mg daily. Treatment should be continued until a total dose of at least 6 g has been given. Otherwise, a negative result is not significant.

Children: If, on the recommendation of a physician, a children's dosage is required, 50 mg daily should be given for the first week. Daily dosage should then be maintained at 100 mg per sq metre of body surface (to nearest 50 mg) until leucopenia or thrombocytopenia occurs or maximum response is obtained.

Natulan Capsules are for oral administration.

Contra-indications, warnings, etc

Contra-indications: Pre-existing severe leucopenia or thrombocytopenia from any cause; severe hepatic or renal damage. Natulan should not normally be administered to patients who are pregnant or to mothers who are breast-feeding.

Precautions: Important. The first stage of treatment with Natulan should be given in hospital under strict medical supervision.

Regular blood counts are of great importance and if during the initial treatment the total white cell count falls to 3,000 per mm³ or the platelet count to 80,000 per mm³, treatment should be suspended temporarily until the leucocyte and/or platelet levels recover, when therapy with the maintenance dose may be resumed.

Treatment should be interrupted on the appearance of allergic skin reactions.

Natulan is a weak MAO inhibitor and therefore interactions with certain foodstuffs and drugs, although very rare, must be borne in mind. Thus, owing to possible potentiation of the effect of barbiturates, narcotics, phenothiazine derivatives and preparations of the imi-

pramine type, these substances should be given in low doses. Intolerance to alcohol may occur.

Side-effects: Loss of appetite and nausea occur in most cases, sometimes with vomiting. These symptoms are usually confined to the first few days of treatment and then tend to disappear.

Like other effective cytostatics, Natulan causes leucopenia and thrombocytopenia. These haematologica changes are almost always reversible and seldom require complete cessation of therapy.

Effects of overdosage and their treatment: Signs of overdosage include severe nausea and vomiting, dizziness, hallucinations, depression and convulsions; hypotension or tachycardia may occur.

Gastric lavage and general supportive treatment should be performed, with prophylactic treatment against possible infection, and frequent blood counts.

Pharmaceutical precautions *Storage:* Recommended maximum storage temperature 30°C. Natulan Capsules should be stored in a dry place.

Legal category POM.

Package quantities Natulan Capsules in packings of 50.

Further information Nil.

Product licence number 0031/5038.

NIPRIDE* ▼

Presentation Ampoules containing the equivalent of 50 mg sodium nitroprusside for reconstitution with 5% Dextrose Injection BP.

Uses Properties: Nipride is a potent, rapidly-acting peripheral vasodilator. Vasodilatation is achieved by a direct and balanced action on both arterial and venous blood vessels. The resultant circulatory effects depend on the initial haemodynamic status of the patient. Thus in hypertensive and normotensive patients without heart failure a fall in systemic blood pressure is produced with little or no effect on cardiac output. In patients with heart failure, reduction of resistance to left ventricular outflow ('afterload') and lowering of raised ventricular pressure ('preload') regularly lead to increased cardiac output usually without significant hypotension.

Duration of effect is brief due to rapid conversion to cyanide and then thiocyanate. This permits minute-by-minute control of the haemodynamic effects.

Indications: Nipride is indicated for the immediate reduction of blood pressure of patients in hypertensive crises. Oral antihypertensive therapy should be started whilst the blood pressure is being controlled with Nipride.

Nipride may also be used for surgical procedure: where a hypotensive technique is appropriate.

Nipride may also be used to improve cardiac function in acute myocardial infarction, aortic or mitral valve disease, cardiomyopathy and other associated causes of acute or chronic heart failure. This includes its intra-operative or post-operative administration in patients undergoing surgery. Haemodynamic improvement is generally associated with an improvement in clinical symptoms of cardiac failure.

Dosage and administration (Nipride is to be given as an intravenous infusion only – see below.)

In patients who are not

ide: Nipride must only be

lministration by any other
olution must be prepared
n below.

oule should be dissolved
1 BP provided. No other

diluent may be used. The resulting solution should be
diluted in 500 to 1,000 ml of 5% Dextrose Injection and
the infusion bottle promptly wrapped in the aluminium
foil provided or other opaque materials to protect it from
light. A self-adhesive label is provided for attaching to
the container of the diluted infusion. Both the initial
solution and the infusion solution should be prepared
immediately before use and any unused portion dis-
carded. The freshly-prepared solution for infusion has a
faint orange-brownish tint. If it is highly coloured, it
should not be used.

Once prepared, the solution should not be stored or
administered for a period longer than four hours. No
preparation other than 5% Dextrose Injection should be
added to the Nipride ampoule or mixed with the Nipride
infusion solution.

Contra-indications, warnings, etc

Contra-indications: Nipride should not be used in the
treatment of compensatory hypertension, e.g. that as-
sociated with conditions such as coarctation of the aorta
or arteriovenous shunt.

Cyanide and thiocyanate may interfere with the metab-
olism of cyanocobalamin (vitamin B₁₂). Nipride is
therefore contra-indicated in patients who are deficient
in this vitamin, have impaired liver function or suffer from
Leber's optic atrophy.

Precautions: Thiocyanate inhibits both the uptake and
binding of iodine. Caution should therefore be exercised
in treating patients with hypothyroidism or severe renal
impairment.

Blood pressure should be monitored frequently during
Nipride administration since the hypotensive effect is
rapid. When the rate of infusion is slowed or administra-
tion is stopped, the blood pressure usually begins to rise
immediately and returns to pre-treatment levels within
one to ten minutes. In view of the rapid onset of action
and potency of the drug, Nipride should preferably be
administered via an infusion pump, microdrip regulator
or any similar device which allows precise control of the
flow rate.

If high infusion rates of Nipride are required to control
the blood pressure, especially during hypotensive pro-
cedures, there is a possibility that a metabolic acidosis
may occur.

Nipride should be used with caution in elderly patients.
Treatment should begin with low doses since they may
be more sensitive to the hypotensive effects of Nipride.

The safety of Nipride in pregnant women has not been
established and it should therefore be used in women of
child-bearing age or during pregnancy only when the
potential benefits are considered to outweigh any
possible disadvantages.

Side-effects: Nausea, retching, diaphoresis, apprehen-
sion, headache, restlessness, muscle-twitching, retro-
sternal discomfort, palpitations, dizziness and abdominal
pain have been noted with a too-rapid reduction in blood
pressure. The symptoms rapidly disappear with slowing
of the rate of infusion of Nipride or temporary withdrawal
of the drug. When administration is continued at a slower
rate of infusion symptoms do not usually recur.

Cyanide inhibits cellular oxidative metabolism. Exces-
sive concentrations of cyanide would be manifested by
tachycardia, sweating, hyperventilation, cardiac arrhyth-
mias and profound metabolic acidosis. Unexplained
cyanosis whilst receiving Nipride may be due to
methaemoglobinaemia.

Effects of overdosage and their treatment: Overdosage

will be manifest by a marked fall in blood pressure below the desired level. The duration of action of Nipride is very short, the hypotensive effects ceasing almost immediately upon discontinuation of the infusion. Pre-treatment blood pressure levels are usually regained within one to ten minutes. Discontinuation of administration or a reduction in the rate of administration are usually sufficient measures for managing overdosage of Nipride.

Cyanide intoxication is best managed by the intravenous injection of sodium nitrite in conjunction with sodium thiosulphate, or alternatively cobalt edetate may be used. Hydroxocobalamin has also been suggested as a cyanide antagonist.

Pharmaceutical precautions Nipride ampoules and infusion solution should be protected from light. When the infusion solution is prepared the container should be wrapped in aluminium foil or other opaque material. Solutions of Nipride should not be stored for more than four hours or administered over a period longer than four hours.

In aqueous solution Nipride yields the nitroprusside ion which reacts with minute quantities of a wide variety of inorganic or organic substances to form reaction products which are frequently highly coloured. If coloration is observed, the solution should be discarded.

No preparation other than 5% Dextrose Injection should be added to the Nipride ampoule or mixed with the Nipride infusion solution.

Storage: Nipride ampoules and infusion should be protected from light.

Legal category POM.

Package quantities Nipride ampoules 50 mg accompanied by ampoules of 2 ml 5% Dextrose Injection BP in packings of 5.

Further information *Availability:* Nipride is available to hospitals only.

Nipride is pharmacologically compatible with other drugs commonly used to treat hypertension. In hypertensive patients who are receiving concomitant therapy smaller doses of Nipride may be required. The hypotensive effect of Nipride is augmented by ganglion-blocking agents.

Product licence number 0031/0102.

NITOMAN*

Presentation Round, pale orange-brown tablets with 'Roche' imprinted across one face and a single break bar on the other, containing 25 mg tetrabenazine.

Uses *Properties:* The central effects of Nitoman closely resemble those of reserpine, but it differs from the latter in having less peripheral activity and being much shorter-acting.

It is known from animal experiments that Nitoman intervenes in the metabolism of biogenic amines, such as serotonin and noradrenaline, and that this activity is mainly limited to the brain. It is thought that the effect of Nitoman on brain amines explains its clinical effects in man.

Indications: Movement disorders associated with organic central nervous system conditions, e.g. Huntington's chorea, hemiballismus and senile chorea.

Dosage and administration *Adults:* Dosage and administration are variable and only a guide is given. An

initial starting dose of 25 mg three times a day is recommended. This can be increased by 25 mg a day every three or four days until 200 mg a day is being given or the limit of tolerance, as dictated by unwanted effects is reached, whichever is the lower dose. If there is no improvement at the maximum dose in seven days, it is unlikely that the compound will be of benefit to the patient, either by increasing the dose or by extending the duration of treatment.

Children: No dosage recommendations are made for the administration of Nitoman to children.

Nitoman Tablets are for oral administration.

Contra-indications, warnings, etc

Contra-indications: Nitoman blocks the action of reserpine.

Precautions: Levodopa should be administered with caution in the presence of Nitoman.

The established medical principle of prescribing medicaments in early pregnancy only when absolutely indicated should be observed.

Side-effects: Side-effects are usually mild with little hypotensive action and few digestive disorders. The main unwanted effect reported to date has been drowsiness, which occurs with higher doses. If depression occurs, it can be controlled by reducing the dose or by giving antidepressant drugs such as the monoamine oxidase inhibitors. However, Nitoman should not be given immediately after a course of any of the monoamine oxidase inhibitors as such treatment may lead to a state of restlessness, disorientation and confusion. In man, a Parkinsonian-like syndrome has been reported on rare occasions, usually in doses above 200 mg per day, but this disappears on reducing the dose.

Effects of overdosage and their treatment: Signs and symptoms of overdosage may include drowsiness, sweating, hypotension and hypothermia. Treatment is symptomatic.

Pharmaceutical precautions *Storage:* Nitoman Tablets should be stored in well-closed containers.

Legal category POM.

Package quantities Nitoman Tablets in packings of 500.

Further information Nil.

Product licence number 0031/5073.

NOBRIUM*

Presentation Capsules with ivory opaque cap and coral opaque body with 'ROCHE 5' printed in red along both cap and body, containing 5 mg medazepam.

Capsules with black cap and coral opaque body with 'ROCHE 10' printed in red along both cap and body, containing 10 mg medazepam.

Uses *Properties:* Nobrium has potent anxiolytic properties. The pharmacological evidence available shows that Nobrium exerts its therapeutic effect by rapidly restoring the disturbed functional balance of the emotional centres in the brain, particularly the limbic system and does not affect the reticular activating system or cortex directly so that its effects are usually obtained without impaired alertness. Nobrium helps in the rationalisation and resolution of emotional conflicts, thus restoring drive and allowing continued normal everyday activities.

indications: Conditions where anxiety is an important component of the patient's overall condition.

Dosage and administration *Adults:* In most cases and in all elderly patients the initial recommended dosage is Nobrium 5 mg twice or three times daily.

This dosage may be increased if necessary until the maximal therapeutic effect is attained or signs of intolerance appear.

The normal dosage lies between 15 and 30 mg a day, but in more severe cases the dosage may be increased to 40 mg a day.

Where insomnia is a feature of the overall condition an additional dose is recommended on retiring.

In the treatment of alcoholism a high dosage is recommended at the onset of treatment. This may then be reduced according to response.

Children: If, on the recommendation of a physician, a child's dosage is required, it is suggested that 1–1.5 mg/kg daily or 5–40 mg daily is given.

Nobrium Capsules are for oral administration.

Contra-indications, warnings, etc *Precautions:* With Nobrium, as with other drugs acting on the central nervous system, patients should be instructed to avoid alcohol while under treatment, since the individual response cannot be foreseen. Like all medicaments of this type, Nobrium may modify patients' reactions (driving ability, operation of machinery, etc) to a varying extent, depending on dosage and individual susceptibility.

The use of high doses of benzodiazepines, especially over prolonged periods, may sometimes lead to dependence, particularly in patients with a history of alcoholism or drug abuse. Treatment in these cases should be withdrawn gradually.

Results obtained in trials with several generations of mice, rats and rabbits indicate that no danger of teratogenic effects need be expected from therapeutic doses of Nobrium. Nevertheless, the established medical principle of prescribing medicaments in early pregnancy only when absolutely indicated should be observed.

Side-effects: Nobrium is well tolerated. Minor side-effects such as fatigue and drowsiness may occasionally occur but usually disappear after the first few days of treatment. Prolonged and extensive clinical and laboratory investigations have revealed no significant changes in the blood picture or liver function.

Effects of overdose and their treatment: As with other benzodiazepine drugs, overdose should not present undue problems of management or threat to life. Symptoms of overdose may include drowsiness, ataxia and dysarthria, with coma in very severe cases.

Treatment is symptomatic, but gastric lavage may be useful if performed soon after ingestion.

Pharmaceutical precautions *Storage:* No special precautions are required.

Legal category POM.

Package quantities Nobrium Capsules 5 mg in packings of 100 and 500.

Nobrium Capsules 10 mg in packings of 100 and 500.

Further information Nil.

Capsules 5 mg 0031/5039

Capsules 10 mg 0031/5040

NOLUDAR*

Presentation Round, white tablets with 'Noludar' imprinted across one face with two break bars on the other, containing 200 mg methypyrone.

Uses *Properties:* Noludar is an effective sedative hypnotic of moderately rapid onset of action and of moderate duration. When Noludar is used in hypnotic doses, sleep is usually induced within 15 minutes to an hour and lasts about six hours. For daytime sedation, a small dose given three or four times daily has been found effective.

Indications: Mild or moderate insomnia. Daytime sedation.

Dosage and administration

	<i>Hypnotic</i>	<i>Sedative</i>
Adults	200–400 mg taken 15 minutes before bedtime	50–100 mg three or four times daily
Children:		
6–10 years	100 mg	50 mg one to three times daily
Over 10 years	100–200 mg	50 mg one to three times daily

Noludar Tablets are for oral administration.

Contra-indications, warnings, etc *Precautions:* With Noludar, as with other drugs acting on the central nervous system, patients should be instructed to avoid alcohol while under treatment, since the individual response cannot be foreseen. Like all medicaments of this type, Noludar may modify patients' reactions (driving ability, operation of machinery, etc) to a varying extent depending on dosage and individual susceptibility.

Side-effects: Noludar has a wide safety margin. Extensive studies have shown that in therapeutic doses, Noludar should have no undesirable effects on respiration, on the circulation, on the gastro-intestinal tract or on haemopoiesis; however, headache and drowsiness may occur.

Effects of overdose and their treatment: Signs and symptoms of overdose may include drowsiness, pyrexia, hypotension, respiratory depression and slight bradycardia. Later, hyperactivity, coma and convulsions may occur.

Gastric lavage should be performed, with general supportive therapy, including oxygen and airway maintenance and intravenous fluids. Metaraminol or nor-adrenaline should be given to correct hypotension; dialysis may be of use.

Pharmaceutical precautions *Storage:* Noludar Tablets should be protected from moisture and light.

Legal category POM.

Package quantities Noludar Tablets in packings of 100.

Further information Nil.

Product licence number 0031/5041.

OMNOPON*

Presentation Round, white to buff tablets marked 'ROCHE' on one side, containing 10 mg papaveretum.

Ampoules containing 20 mg papaveretum in 1 ml. The ampoule solution is colourless to pale brown.

Uses Properties: Omnopon, a potent analgesic, contains both the phenanthrene and isoquinoline groups of opium alkaloids. The former includes codeine and morphine which exert a marked narcotic action on the central nervous system. The second group is represented by papaverine, which acts mainly at the periphery as an antispasmodic, and noscapine.

Indications: Pre-operative medication; relief of post-operative pain; relief of severe chronic pain, particularly that of inoperable carcinoma, relief of pain and anxiety in coronary thrombosis; for severe pain associated with spasm as in renal and biliary colic.

Dosage and administration Adults: Single dose of 10 to 20 mg by mouth or by injection, usually not to be repeated more often than 4 hourly.

Children: Usual dosage:

1 to 5 years: 2.5 to 5 mg as a maximum single dose.

6 to 12 years: 5 to 10 mg as a maximum single dose.

Omnopon Tablets are for oral administration. They are not recommended for use in children under 12 years of age.

Omnopon ampoules are for intramuscular, intravenous or subcutaneous injection. They are not recommended for use in infants under 1 year of age.

Omnopon ampoule solution may be diluted with Water for Injection. Such dilution is recommended for accurate titration of children's doses.

Maintenance of stability cannot be guaranteed when Omnopon Ampoule solution is diluted.

Contra-indications, warnings, etc

Contra-indications: Omnopon should not be given to comatose patients or patients with respiratory depression or obstructive airways disease. It should not be administered to patients who are receiving monoamine oxidase inhibitors or within two weeks of their withdrawal.

Precautions: Omnopon should only be given with caution, and in reduced dosage, to neonates and premature infants, elderly and debilitated patients, and in patients with head injuries, severe hepatic or renal impairment, biliary tract disorders, hypothyroidism, adrenocortical insufficiency, shock, prostatic hypertrophy, and supraventricular tachycardia.

Caution is also required in patients exhibiting acute alcoholism, raised intracranial pressure or convulsive disorders. Omnopon depresses respiratory function and should be administered with particular care in patients with respiratory insufficiency.

The effects of Omnopon may be potentiated by concurrent administration of other central nervous system depressants, including anaesthetic agents. Concomitant administration of Omnopon with phenothiazines may induce severe hypotension. Patients should be instructed to avoid alcohol while under treatment, since the individual response cannot be foreseen.

Omnopon may modify patients' reactions (driving ability, operation of machinery, etc.) to a varying extent, depending on dosage, administration and individual susceptibility.

There is inadequate evidence of safety of Omnopon in human pregnancy, but the drug has been widely used for many years without apparent ill-consequence, and animal studies have not shown any hazard. Nevertheless, the established medical principle of prescribing medi-

caments in early pregnancy only when absolutely indicated should be observed.

Omnopon crosses the placenta and is also secreted in breast milk. This should be borne in mind when considering its use in patients during pregnancy or breast feeding. Administration in labour may cause respiratory depression in the newborn infant.

Repeated administration of Omnopon may induce tolerance to the drug, with a tendency to increasing dosage requirements to obtain the desired effect, or to physical and psychological dependence of the morphine type, with the development of withdrawal symptom: after abrupt cessation of therapy. Cross-tolerance between narcotic analgesics can occur.

Side-effects: Nausea and vomiting may be troublesome. Constipation and confusion may occur.

Effects of overdosage and their treatment: Signs of overdosage are similar to those with morphine but occur to a lesser extent; they include pin-point pupils, depressed respiration and coma. In severe poisoning there may be dilatation of the pupils, shock, severe respiratory depression and pulmonary oedema.

Gastric lavage should be performed soon after ingestion and intensive supportive therapy carried out. Lorfan 1-2 mg i.v., naloxone or nalorphine are antidotes.

Pharmaceutical precautions Storage: Omnopon Ampoules should be protected from light. Omnopon Tablets in blister packs should be stored in a dry place and protected from light. The recommended maximum storage temperature for Omnopon Ampoules is 25°C and for Omnopon Tablets is 30°C.

Legal category POM; MDA.

Package quantities Omnopon Tablets in cartons of 500, each carton containing 10 packs of 50 tablets in blister strips of 5 tablets.

Omnopon Ampoules in packings of 10.

Further information Nil.

Tablets 10 mg 0031/5098

OMNOPON* SCOPOLAMINE

Presentation Ampoules containing 20 mg of papaveretum and 0.4 mg of hyoscine (scopolamine) hydrobromide in 1 ml. The ampoule solution is almost colourless to pale yellow.

Uses Properties: Omnopon-scopolamine combines the properties of the opium alkaloids with those of scopolamine. Thus it is an analgesic and sedative and has a marked inhibitory effect on the secretions.

Indication: Pre-anaesthetic medication.

Dosage and administration Adults: Usually $\frac{1}{2}$ to one ampoule injected $\frac{1}{2}$ -1 hour before anaesthesia.

Children:

Weight	Omnopon	Volume of Omnopon-scopolamine solution
10 kg	6 mg	0.3 ml
20 kg	12 mg	0.6 ml
30 kg	18 mg	0.9 ml
35 kg	20 mg	1.0 ml

ampoules are for intramuscular use. The ampoule solution may be diluted. Such dilution is not recommended for children's doses. It cannot be guaranteed when the ampoule solution is diluted.

Warnings, etc

Omnopon-scopolamine should not be given to patients with active airways disease. It should not be given to patients who are receiving or within two weeks of

scopolamine should only be given at the recommended dosage, to neonates and debilitated patients, patients with severe hepatic or renal impairment, hypothyroidism, adrenalectomy, prostatic hypertrophy, etc.

Patients exhibiting acute hypertension or convulsive activity should be given scopolamine depresses respiratory function with particular care and efficiency.

Omnopon-scopolamine may be potentiated by other central nervous system depressants including anaesthetics. Administration of Omnopon-scopolamine may induce severe hypotension. It is recommended to avoid alcohol and to observe the individual response.

Do not modify patients' reaction to anaesthesia of machinery, etc.) to avoid misadministration and

The safety of Omnopon-scopolamine, but the drug has been found to have no apparent ill-effects. It is not shown any hazard. The medical principle of premedication is pregnancy only when observed.

It crosses the placenta and is excreted in the milk. It should be borne in mind that during pregnancy or labour may cause hypotension in the newborn infant.

Omnopon-scopolamine is a sedative drug, with a tendency to cause drowsiness to obtain the desired analgesic effect. Physiological dependence of withdrawal of therapy. Cross-sensitization can occur.

Itching usually occurs. Unpleasant. Constipation

Adverse treatment: Signs of overdosage are seen with morphine. Pinpoint pupils and impaired level of consciousness. In severe poisoning the pupils, shock, severe respiratory oedema.

Intensive supportive therapy should be carried out. Lofran* 1-2 mg i.v., naloxone or nalorphine are antidotes. If excitement due to scopolamine occurs, Valium* Roche or short-acting barbiturates may be administered.

Pharmaceutical precautions Storage: Omnopon-scopolamine Ampoules should be protected from light. The recommended maximum storage temperature is 25°C.

Legal category POM; MDA.

Package quantities Omnopon-scopolamine Ampoules in packings of 10.

Further information Nil.

PETHIDINE ROCHE

Presentation Round, white tablets with 'ROCHE' imprinted on one face, containing 25 mg pethidine hydrochloride.

Round white tablets with 'ROCHE' imprinted on one face, containing 50 mg pethidine hydrochloride.

Ampoules containing 50 mg pethidine hydrochloride in 1 ml. The ampoule solution is colourless to pale yellow.

Ampoules containing 100 mg pethidine hydrochloride in 2 ml. The ampoule solution is colourless to pale yellow.

Uses Properties: Pethidine Roche combines analgesic and antispasmodic properties; it is relatively short-acting and has little soporific effect. These properties make Pethidine Roche particularly useful for pain relief in labour and as an adjunct to nitrous oxide-oxygen anaesthesia.

Indications: Obstetric analgesia; moderate to severe pain; premedication and analgesia during anaesthesia.

Dosage and administration Adults: The normal single dose, usually not to be repeated more often than four-hourly, is as follows:

Oral: 50-150 mg.

Intramuscular or subcutaneous injection: 25-100 mg.

Intravenous injection: 25-50 mg.

Children: Single dose of 0.5-2 mg/kg body weight orally or intramuscularly.

Pethidine Roche Tablets are for oral administration. Pethidine Roche Ampoules are for intramuscular, intravenous or subcutaneous injection.

Pethidine Roche Ampoule solution may be diluted with Water for Injection. Such dilution is recommended for accurate titration of children's doses.

Maintenance of stability cannot be guaranteed when Pethidine Roche Ampoule solution is diluted.

Contra-indications, warnings, etc

Contra-indications: Pethidine should not be given to comatose patients or to patients with respiratory depression or obstructive airways disease. It should not be administered to patients who are receiving monoamine oxidase inhibitors or within two weeks of their withdrawal.

Precautions: Pethidine should only be given with caution, and in reduced dosage, to neonates and premature infants, elderly and debilitated patients, and in patients with head injuries, severe hepatic or renal impairment, biliary tract disorders, hypothyroidism, ad-

renocortical insufficiency, shock, prostatic hypertrophy, and supraventricular tachycardia.

Caution is also required in patients exhibiting acute alcoholism, raised intracranial pressure or convulsive disorders. Pethidine depresses respiratory function and should be administered with particular care in patients with respiratory insufficiency.

The effects of pethidine may be potentiated by concurrent administration of other central nervous system depressants, including anaesthetic agents. Concomitant administration of pethidine with phenothiazines may induce severe hypotension. Patients should be instructed to avoid alcohol while under treatment, since the individual response cannot be foreseen.

Pethidine may modify patients' reactions (driving ability, operation of machinery, etc.) to a varying extent, depending on dosage, administration and individual susceptibility. There is inadequate evidence of safety of pethidine in human pregnancy, but the drug has been widely used for many years without apparent ill-consequence, and animal studies have not shown any hazard. Nevertheless, the established medical principle of prescribing medicaments in early pregnancy only when absolutely indicated should be observed.

Pethidine crosses the placenta and is also secreted in breast milk. This should be borne in mind when considering its use in patients during pregnancy or breast feeding. Administration in labour may cause respiratory depression in the newborn infant.

Repeated administration of pethidine may induce tolerance to the drug, with a tendency to increasing dosage requirements to obtain the desired effect, or to physical and psychological dependence of the morphine type, with the development of withdrawal symptoms after abrupt cessation of therapy. Cross-tolerance between narcotic analgesics can occur.

Side-effects: Pethidine may cause mild euphoria, dizziness, nausea and vomiting, hypotension and respiratory depression.

Effects of overdosage and their treatment: In acute overdosage, signs and symptoms may include incoordination, tremors and convulsions followed by respiratory depression and coma.

Gastric lavage should be performed soon after ingestion, and intensive supportive therapy carried out. Lofran* 1-2 mg i.v., naloxone or nalorphine are antidotes. The urinary excretion can be increased by rendering the urine acid by the administration of ammonium chloride.

Pharmaceutical precautions *Storage:* Pethidine Roche Tablets in blister packs should be stored in a dry place.

The recommended maximum storage temperature for Pethidine Roche Ampoules is 30°C.

Legal category POM; MDA.

Package quantities Pethidine Roche Tablets 25 mg in cartons of 500, each carton containing 10 packs of 50 tablets in blister strips of 5 tablets.

Pethidine Roche Tablets 50 mg in cartons of 500, each carton containing 10 packs of 50 tablets in blister strips of 5 tablets.

Pethidine Roche Ampoules containing 50 mg in 1 ml in packings of 10.

PETHILORFAN*

Presentation Ampoules containing pethidine hydrochloride 50 mg and levallorphan tartrate 0.625 mg in 1 ml. The ampoule solution is colourless to pale yellow.

Ampoules containing pethidine hydrochloride 100 mg and levallorphan tartrate 1.25 mg in 2 ml. The ampoule solution is colourless to pale yellow.

Uses *Properties:* Pethilorfan, an analgesic preparation is a combination of pethidine with the narcotic antagonist Lofran* (levallorphan tartrate). It has been shown that Lofran prevents or reduces respiratory depression caused by pethidine. When pethidine and Lofran are combined in the ratio 100:1.25, the respiratory depressant effect of pethidine is inhibited.

Indications: Analgesia in obstetrics, anaesthesia, pre-anaesthetic medication; minor surgical procedures and post-operative pain.

Dosage and administration Single doses should be used which are not to be repeated more often than four hourly.

Adults: Obstetrics: When labour is firmly established to 3 ml Pethilorfan may be given intramuscularly.

Premedication: Up to 2 ml Pethilorfan intramuscularly may be given 1 hour before operation.

Adjunct to nitrous oxide-oxygen anaesthesia: Pethilorfan is used in the same way as pethidine alone, 0.5 to 1 ml being given when anaesthesia is established.

Minor surgical procedures: Up to 2 ml Pethilorfan intramuscularly, or up to 1 ml Pethilorfan intravenously may be given.

For the treatment of post-operative and other pain Pethilorfan may be used in the same way as pethidine.

Children: Children may be given a single dose containing pethidine 0.5 to 2.0 mg/kg body weight, intramuscularly.

Pethilorfan ampoules are for intramuscular, intravenous or subcutaneous injection.

Pethilorfan Ampoule solution may be diluted with Water for Injection. Such dilution is recommended for accurate titration of children's doses.

Maintenance of stability cannot be guaranteed when Pethilorfan ampoule solution is diluted.

Contra-indications, warnings, etc

Contra-indications: Pethilorfan should not be given to comatose patients or to patients with respiratory depression or obstructive airways disease. It should not be administered to patients who are receiving monoamine oxidase inhibitors or within two weeks of their withdrawal.

Precautions: Pethilorfan should only be given with caution, and in reduced dosage, to neonates and premature infants, elderly and debilitated patients, and in patients with head injuries, severe hepatic or renal impairment, biliary tract disorders, hypothyroidism, adrenocortical insufficiency, shock, prostatic hypertrophy and supraventricular tachycardia.

Caution is also required in patients exhibiting acute alcoholism, raised intracranial pressure or convulsive disorders. Pethilorfan depresses respiratory function and

ould be administered with particular care in patients with respiratory insufficiency.

The effects of Pethilorfan may be potentiated by concurrent administration of other central nervous system depressants, including anaesthetic agents. Concurrent administration of Pethilorfan with phenothiazines may induce severe hypotension. Patients should be instructed to avoid alcohol while under treatment since the individual response cannot be foreseen.

Pethilorfan may modify patients' reactions (driving ability, operation of machinery, etc.) to a varying extent, depending on dosage, administration and individual susceptibility.

There is inadequate evidence of safety of Pethilorfan in human pregnancy, but the drug has been widely used for many years without apparent ill-consequence, and animal studies have not shown any hazard. Nevertheless, the established medical principle of prescribing medications in early pregnancy only when absolutely indicated should be observed.

Pethilorfan crosses the placenta and is also secreted in breast milk. This should be borne in mind when considering its use in patients during pregnancy or breastfeeding. Administration in labour may cause respiratory depression in the newborn infant.

Repeated administration of Pethilorfan may induce tolerance to the drug, with a tendency to increasing dosage requirements to obtain the desired effect, or to physical and psychological dependence of the morphine type, with the development of withdrawal symptoms after abrupt cessation of therapy. Cross-tolerance between narcotic analgesics can occur.

Side-effects: Mild euphoria, dizziness, nausea and vomiting, hypotension and respiratory depression may occur.

Effects of overdosage and their treatment: In acute overdosage signs and symptoms may include incoordination, tremors, convulsions and coma. Pethidine alone may cause respiratory depression; however, in combination with Lofran, this is less likely to occur.

Intensive supportive therapy should be carried out. Pethilorfan* 1–2 mg i.v., naloxone or nalorphine are pethidine antidotes. The urinary excretion of pethidine can be increased by rendering the urine acid by the administration of ammonium chloride.

Pharmaceutical precautions *Storage:* Pethilorfan ampoules should be protected from light.

Legal category POM; MDA.

Package quantities Pethilorfan Ampoules containing 0 mg of pethidine hydrochloride and 0.625 mg of orfan in 1 ml in packings of 10.

Pethilorfan Ampoules containing 100 mg of pethidine hydrochloride and 1.25 mg of Lofran in 2 ml in packings of 10.

PROSTIGMIN*

Presentation Round, white tablets with 'PROSTIGMIN' imprinted on one face with a single break bar on the other, containing 15 mg neostigmine bromide.

Ampoules containing 0.5 mg neostigmine methyl-

sulphate in 1 ml. The ampoule solution is almost colourless to pale yellow.

Ampoules containing 2.5 mg neostigmine methylsulphate in 1 ml. The ampoule solution is almost colourless to pale yellow.

Uses Properties: Prostigmin is an antagonist to cholinesterase, the enzyme which normally destroys acetylcholine. The action of Prostigmin can briefly be described, therefore, as the potentiation of naturally occurring acetylcholine.

Indications: Myasthenia gravis; antidote to curariform drugs; paralytic ileus; post-operative distension; chronic constipation; urinary retention; heartburn of pregnancy; paroxysmal tachycardia.

Dosage and administration *Adults – Myasthenia gravis:* A daily dose of 5–20 tablets by mouth or 1–2.5 mg by injection is commonly given, but doses higher than these may be needed by some patients. The daily doses should be spread over the day and taken at times when they are most required. With some of the daily doses it may be necessary to take atropine or some other anticholinergic drug.

Antidote to curariform drugs: Prostigmin 1–5 mg intravenously, atropine 0.4–1.25 mg. The atropine is often given some minutes before the Prostigmin.

Other indications: The usual adult dose is 1–2 tablets by mouth or 0.5–2.5 mg by subcutaneous or intramuscular injection; the frequency of dosage may be varied according to the needs of the patient.

Children: If on the recommendation of a physician a children's dosage is required, then the following is given as a guide:

Myasthenia gravis: Newborn infants: Usually 0.05–0.25 mg by injection or 1–5 mg orally every four hours.

Older children: 0.2–0.5 mg daily by injection or 15–60 mg daily orally.

Other indications: 2.5–15 mg orally 0.125–1 mg by injection.

Prostigmin Tablets are for oral administration. Prostigmin Ampoules are for intramuscular, intravenous or subcutaneous injection.

Prostigmin Ampoule solution may be diluted with Water for Injection.

Maintenance of stability cannot be guaranteed when Prostigmin preparations are diluted.

Contra-indications, warnings, etc *Precautions:* Care should be taken in administering Prostigmin to patients with bronchial asthma.

Side-effects: These may include nausea and vomiting, increased salivation, diarrhoea and abdominal cramps.

Effects of overdosage and their treatment: Signs of overdosage due to muscarinic effects may include abdominal cramps, increased peristalsis, diarrhoea, nausea and vomiting, increased bronchial secretions, salivation, diaphoresis and miosis. Nicotinic effects consist of muscular cramps, fasciculations and general weakness. Bradycardia and hypotension may also occur. Artificial respiration should be instituted if respiratory depression is severe. Atropine sulphate 1–2 mg intravenously is an antidote to the muscarinic effects.

Pharmaceutical precautions *Storage:* The recommended maximum storage temperature for Prostigmin Ampoules 2.5 mg is 25°C. All Prostigmin preparations should be protected from light.

Ampoules 2.5 mg 0031/5085

Tablets 0031/5086

RIMIFON***Presentation** Ampoules containing 50 mg isoniazid in 2 ml. The ampoule solution is almost colourless.**Uses Properties:** Rimifon is a highly active tuberculostatic drug. It has a high rate of diffusion so that the tuberculostatic action affects intracellular as well as extracellular bacilli.**Indications:** All forms of pulmonary and extra-pulmonary tuberculosis.**Dosage and administration** Rimifon Ampoules are for intramuscular, intrapleural, intrathecal or intravenous injection.

The usual intramuscular or intravenous dose for adults is 200–300 mg daily, for children 100–300 mg daily, but doses much larger than these are sometimes given, especially in conditions such as tuberculous meningitis.

Intrathecal use: In tuberculous meningitis Rimifon 25–50 mg daily may be given intrathecally as a supplement to oral isoniazid for adults. Children may be given 10–20 mg daily according to age.**Intrapleural use:** 50–250 mg may be instilled intrapleurally after aspiration of pus, the dosage of oral isoniazid on that day being correspondingly reduced. The ampoule solution is also used for the local treatment of tuberculous ulcers, for irrigation of fistulae, etc.

It is usual to give Rimifon in conjunction with streptomycin or PAS, or both, provided that the organisms are sensitive to these drugs. Rimifon can also be given together with other antitubercular drugs, e.g. rifampicin, ethambutol, cycloserine.

Rimifon Ampoule solution may be diluted with Water for Injection.

Maintenance of stability cannot be guaranteed when Rimifon Ampoule solution is diluted.

Contra-indications, warnings, etc Side-effects:These include peripheral neuritis, which occurs mainly in patients receiving high doses, or in those taking prolonged courses of the drug. Concurrent Benadon* (vitamin B₆, pyridoxine) can largely prevent the development of neuritis; suggested dose 50 mg daily.

Hypersensitivity reactions, purpura, agranulocytosis and pellagra are rare complications of isoniazid therapy. Psychotic episodes or epileptiform fits are occasionally encountered, usually in patients with a history of epilepsy or of previous psychotic illness; these manifestations usually subside rapidly on withdrawing the drug.

Effects of overdosage and their treatment: Signs of minor overdosage are similar to the side-effects listed. In severe poisoning metabolic acidosis, elevated blood sugar levels, seizures and coma may occur. Intravenous pyridoxine is an antidote to isoniazid poisoning. Sodium bicarbonate may be used to correct metabolic acidosis and intravenous Valium* Roche to control convulsions.**Pharmaceutical precautions Storage:** The recommended maximum storage temperature for Rimifon Ampoules is 25°C; the Ampoules should be protected from light.**Legal category** POM.**Package quantities** Rimifon Ampoules in packings of 10.**Further information** Nil.**Product licence number** 0031/5109.**RO-A-VIT*****Presentation** Round, cream, sugar-coated tablet with 'ROCHE' printed in red on one face, containing 50,000 i.u. retinol (vitamin A) as the acetate.

Ampoules containing 300,000 i.u. retinol as the palmitate (approx. 165 mg) in 1 ml oily solution.

Uses Properties: Ro-A-Vit is a synthetic vitamin A preparation. Vitamin A may be considered to act chiefly as a regulator of the growth and activity of epithelial tissues. It plays an essential role in the visual cycle through its participation in the synthesis of visual purple by the retina.

The cardinal signs and symptoms of vitamin A deficiency are those affecting the eyes, such as xerosis, swelling and destruction of the cornea and night-blindness. Changes in the skin and changes in the mucous membranes of the respiratory, digestive and urinary tracts have been reported.

Indications: Prevention and treatment of vitamin A deficiencies.

Ro-A-Vit Ampoules are indicated when oral therapy is inappropriate (e.g. in malabsorption syndrome).

Dosage and administration Tablets – Adults: 1–6 tablets daily (50,000–300,000 i.u.).**Children:** If, on the recommendation of a physician, a child's dosage is required, then it is suggested that up to 50,000 i.u. daily be given according to age.**Ampoules: Adults and children:** A maintenance dosage of ½–1 ampoule by deep intramuscular injection once monthly is usually sufficient but in acute deficiency states the same dosage may be given once weekly. When prolonged therapy with high, weekly dosages of vitamin A is required it is suggested that Ro-A-Vit Ampoules be given in courses of no longer than six weeks separated by treatment-free intervals of two weeks so that the patient can be observed for signs of possible hypervitaminosis A.

Ro-A-Vit Tablets are for oral administration.

Ro-A-Vit Ampoule solution is only suitable for deep intramuscular injection.

Contra-indications, warnings, etc Precautions:

During the early months of pregnancy, high doses of vitamin A should be avoided or only be administered where there is a firm indication for their use and under doctor's instructions.

Effects of overdose and their treatment: Massive doses of vitamin A are required to produce toxicity and therefore it is extremely unlikely that even exceptionally large single doses would cause hypervitaminosis A (except possibly in children). Manifestations of acute overdose in children include severe headache, nausea, vomiting, drowsiness, irritability and pruritus. In chronic overdose in children the following have been noted after periods of 2½–15 months: hydrocephaly, osteopenia, painful swellings over the long bones, with bone and joint pains, hyperostosis, and deep, hard, tender swellings in the extremities. Adults are likely to complain of bone and joint pains. The vitamin should be discontinued. Symptoms of acute overdose subside within 72 hours and of chronic overdose over a period of several months, without further treatment.

Pharmaceutical precautions *Storage:* Ro-A-Vit tablets should be stored in well-closed containers. The recommended maximum storage temperature for Ro-A-Vit Tablets is 25°C.

Ro-A-Vit Ampoules should be protected from light. Recommended maximum storage temperature 25°C.

Legal category Tablets P.

ROCALTROL* ▼

Presentation Soft gelatine capsules, one length red opaque and the other white opaque, containing 0.25 microgram calcitriol. Soft gelatine capsules, both lengths red opaque, containing 0.5 microgram calcitriol.

Uses *Properties:* Calcitriol has the greatest biological activity of the known vitamin D metabolites and is normally formed in the kidneys from its immediate precursor, 25-hydroxycholecalciferol. In physiological amounts it augments the intestinal absorption of calcium and phosphate and plays a significant part in the regulation of bone mineralisation. The defective production of calcitriol in chronic renal failure contributes to the abnormalities of mineral metabolism found in that disorder.

Rocaltrol is a synthetic preparation of calcitriol. Oral administration of Rocaltrol to patients with chronic renal failure compensates for impaired endogenous production of calcitriol which is decreased when the glomerular filtration rate falls below 30 ml/min. Consequently, intestinal malabsorption of calcium and phosphate and the resulting hypocalcaemia are improved, thereby reversing the signs and symptoms of bone disease.

The onset and reversal of the effects of Rocaltrol are more rapid than those of other compounds with vitamin D activity and adjustment of the dose can be achieved sooner and more precisely. The effects of inadvertent overdose can also be reversed more readily.

Indications: Rocaltrol is indicated for the correction of the abnormalities of calcium and phosphate metabolism in patients with renal osteodystrophy.

Dosage and administration The dose of Rocaltrol should be carefully adjusted for each patient according to the biological response so as to avoid hypercalcaemia. The effectiveness of treatment depends in part on an adequate daily intake of calcium, which should be augmented by dietary changes or supplements if necessary. The capsules should be swallowed with a little water.

Adults: It is suggested that treatment should be started with two to four 0.5 mcg capsules of Rocaltrol daily and serum calcium levels monitored at weekly intervals. The daily dose may be increased by increments of 0.25–0.5 mcg to a total of 2 or 3 mcg daily according to the biological response. When dose requirements are stable serum calcium levels may be monitored at intervals of two to four weeks.

When there is biochemical or radiographic evidence of bone healing the requirements for Rocaltrol generally decrease. The dose should then be adjusted to avoid hypercalcaemia.

Higher doses of Rocaltrol may be required when barbiturates or anticonvulsants are given concurrently but this should rarely exceed 5 mcg daily. Reduction of dose is necessary if such drugs are withdrawn.

Children: Dosage in children has not been established.

Rocaltrol capsules are for oral administration only.

Contra-indications, warnings, etc

Contra-indications: Rocaltrol should not be given to patients with hypercalcaemia or evidence of metastatic calcification.

Precautions: All other vitamin D compounds and their derivatives, including proprietary compounds or food-stuffs which may be 'fortified' with vitamin D, should be withheld during treatment with Rocaltrol.

Treatment does not obviate the need to control plasma phosphate with phosphate binding agents. Since Rocaltrol affects phosphate transport in the gut and bone, the dose of phosphate binding agent may need to be modified.

The safety of Rocaltrol during pregnancy has not been established since to date there has been no experience in pregnancy. The usual caution in prescribing any drug for women of child-bearing age should be observed.

Side-effects: Hypercalcaemia and hypercalciuria are the major side-effects of Rocaltrol and indicate excessive dosage. The clinical features of hypercalcaemia include anorexia, nausea, vomiting, headache, weakness, apathy and somnolence. More severe manifestations may include thirst, dehydration, polyuria, nocturia, abdominal pain, paralytic ileus and cardiac arrhythmias. Rarely, overt psychosis and metastatic calcification may occur. The relatively short biological half-life of Rocaltrol permits rapid elimination of the compound when treatment is stopped and hypercalcaemia will recede within two to seven days. The rate of reversal of biological effects is more rapid than when other vitamin D derivatives are used.

Mild, non-progressive and reversible elevations in levels of liver enzymes (SGOT, SGPT) have been noted in a few patients treated with Rocaltrol, but no pathological changes in the liver have been reported.

Effects of overdose and their treatment: In acute overdose gastric lavage should be considered as soon after ingestion as possible provided that the drug was taken within the previous six to eight hours.

Should hypercalcaemia occur, Rocaltrol should be discontinued until plasma calcium levels have returned

to normal. A low-calcium diet will speed this reversal. Rocaltrol can then be restarted at a lower dose or given in the same dose but at less frequent intervals than previously. Severe hypercalcaemia may be treated by ensuring adequate hydration, inducing a diuresis where practicable and by general supportive measures. Calcitonin may increase the rate of fall of serum calcium when bone resorption is increased.

In patients treated by intermittent haemodialysis, a low concentration of calcium in the dialysate may also be used.

Pharmaceutical precautions *Storage:* Rocaltrol capsules should be protected from heat.

RONICOL*

Presentation Round, white tablets with 'RONICOL' imprinted across one face with a single break bar on the other, containing 59.4 mg nicotine alcohol tartrate (equivalent to 25 mg nicotine alcohol).

Uses *Properties:* Ronicol is the alcohol corresponding to nicotine acid and has similar vasodilator properties. Its action is more sustained than that of nicotine acid because, in addition to the vasodilator effect of the alcohol itself, partial metabolism of the alcohol results in the gradual release of nicotine acid. Ronicol exerts a direct vasodilator action on the walls of small arteries and arterioles; there is a slight transient tendency towards a fall in blood pressure and slowing of the pulse.

Indications: Circulatory disorders, including peripheral vascular disease, vascular spasm (e.g. Raynaud's disease and acrocyanosis). Ménière's syndrome, chilblains, eye conditions due to deficient retinal circulation.

Dosage and administration *Adults:* 1–2 tablets four times daily.

Children: No dosage recommendations are made for the administration of Ronicol to children.

Ronicol Tablets are for oral administration.

Contra-indications, warnings, etc *Precautions:* Care should be taken in the long-term administration of high doses of Ronicol in patients with pre-diabetic or diabetic metabolic disorders.

Side-effects: Ronicol is very well tolerated and may be given over long periods without toxic effects. Mild, transient flushing of the face and a feeling of warmth in the region of the head may be experienced when the patient is taking an optimal dose.

Effects of overdose and their treatment: In overdose, gastric irritation, diarrhoea, flushing and general vasodilatation and possibly hypotension may occur.

Gastric lavage should be performed and symptoms treated as they arise.

Pharmaceutical precautions *Storage:* Ronicol should be stored in well-closed containers.

Legal category P.

Package quantities Ronicol Tablets in packings of 100.

Further information Nil.

Product licence number 0031/5113.

RONICOL* TIMESPAN*

Presentation Brown-red, sugar-coated tablets with 'ROCHE' printed in black across one face containing 357 mg nicotine alcohol tartrate (equivalent to 150 mg nicotine alcohol).

Uses *Properties:* Ronicol Timespan Tablets are slow release tablets, the active principle being Ronicol, which is the alcohol corresponding to nicotine acid and has similar vasodilator properties. In addition to the vasodilator effect of the alcohol itself, partial metabolism of the alcohol results in the gradual release of nicotine acid. The compound exerts a direct vasodilator action on the walls of small arteries and arterioles which is maintained for 12 hours. There is a slight transient tendency towards a fall in blood pressure and slowing of the pulse.

Indications: Circulatory disorders, including peripheral vascular disease, vascular spasm (e.g. Raynaud's disease and acrocyanosis). Ménière's syndrome, chilblains, eye conditions due to deficient retinal circulation.

Dosage and administration *Adults:* 1 or 2 tablet night and morning, depending on the severity of the condition. They should be swallowed whole.

Children: No dosage recommendations are made for the administration of Ronicol Timespan to children.

Ronicol Timespan Tablets are for oral administration.

Contra-indications, warnings, etc *Precautions* Care should be taken in the long-term administration of high doses of Ronicol in patients with pre-diabetic or diabetic metabolic disorders.

Side-effects: Ronicol Timespan is very well tolerated and may be given over long periods without toxic effects. Mild, transient flushing of the face and a feeling of warmth in the region of the head may be experienced when the patient is taking an optimal dose.

Effects of overdose and their treatment: In overdose, gastric irritation, diarrhoea, flushing and general vasodilatation and possibly hypotension may occur.

Gastric lavage should be performed and symptoms treated as they arise.

Pharmaceutical precautions *Storage:* Ronicol Timespan should be stored in well-closed containers.

Legal category P.

Package quantities Ronicol Timespan Tablets in packings of 100.

Further information Nil.

Product licence number 0031/5114.

SYNKAVIT*

Alternative name: Menadiol sodium diphosphate.

Presentation Round, white tablets with 'SYNKAVIT' imprinted on one face with a single break bar across the other, containing 12.63 mg of the tetra-sodium salt of 2

ethyl-1,4-naphthahydroquinone diphosphate (equivalent to 10 mg of the free ester).

Ampoules containing 126.3 mg of the tetra-sodium salt of 2-methyl-1,4-naphthahydroquinone diphosphate (equivalent to 10 mg of the free ester) in 1 ml. The ampoule solution is colourless to pale yellow.

Ampoules containing 126.3 mg of the tetra-sodium salt of 2-methyl-1,4-naphthahydroquinone diphosphate (equivalent to 100 mg of the free ester) in 2 ml. The ampoule solution is colourless to pale yellow.

Uses Properties: Synkavit is a water-soluble vitamin K analogue. The presence of vitamin K is essential for the formation within the body of prothrombin, factor VII, factor IX and factor X. Lack of vitamin K leads to increased tendency to haemorrhage.

Indications: Synkavit is indicated in the treatment of haemorrhage or threatened haemorrhage associated with a low blood level of prothrombin or factor VII.

The main indications include: obstructive jaundice (before and after surgery); haemorrhage after dental extractions; prevention of neonatal haemorrhage; menorrhagia.

Synkavit, in large doses, may be used as a 'radio-sensitiser' in the treatment of cancer.

Dosage and administration Adults: Usual therapeutic dose – 10–40 mg daily. Large doses (as a 'radiosensitiser') – 100 mg by injection.

Children: If, on the recommendation of a physician, a child's dosage is required, it is suggested that 5–10 mg daily be given.

For haemorrhagic disease of the newborn: Administered prophylactically to the mother: 10 mg by mouth daily for three to four days before labour, or 5 mg by injection during labour.

Administered to the infant: although Synkavit has been used successfully for many years in newborn infants for the prevention and treatment of haemorrhagic disease, it is now considered that Konakion* (vitamin K₁) is preferable for this purpose.

Synkavit Tablets are for oral administration.

Synkavit Ampoules are for intramuscular, intravenous or subcutaneous injection.

Synkavit Ampoule solution may be diluted with Water or Injection.

Maintenance of stability cannot be guaranteed when Synkavit Ampoule solution is diluted.

Contra-indications, warnings, etc Precautions: Caution should be exercised in administering Synkavit and other vitamin K analogues to premature infants. Doses in excess of 10 mg have been associated with hyperbilirubinaemia in such infants. In full-term infants a single dose of up to 5 mg is adequate and without danger.

Pharmaceutical precautions Storage: Recommended maximum storage temperature for Synkavit Tablets and Ampoules 100 mg is 30°C, for Synkavit Ampoules 10 mg 25°C. All Synkavit preparations should be protected from light.

Legal category Tablets P
Ampoules POM.

Package quantities Synkavit Tablets in packings of 10.

Synkavit Ampoules 10 mg in 1 ml in packings of 10.

Synkavit Ampoules 100 mg in 2 ml in packings of 10.

Further information In almost all circumstances Synkavit is as effective as the natural vitamin (vitamin K₁). It is not fully effective however as an antidote to anticoagulant drugs of the dicoumarol type and for this purpose, vitamin K₁ (Konakion*) should be used.

Ampoules 100 mg	0031/5117

TARACTAN*

Presentation Round, pink, sugar-coated tablets with 'ROCHE' printed in red across one face, containing 15 mg chlorprothixene.

Round, dark red-brown, sugar-coated tablets with 'ROCHE' printed in white across one face, containing 50 mg chlorprothixene.

Uses Properties: Taractan is a major tranquillising drug. Animal experiments have shown that it has sedative and adrenolytic properties similar to those of chlorpromazine, but it has much greater anticholinergic activity. It also has antiserotonin, antihistamine and anti-emetic activity.

Indications: Psychoses and psychoneuroses: for the treatment of agitation, anxiety, insomnia, hallucinations, delusions and associated disturbances, without the risk of exacerbating any underlying depression.

Dosage and administration Adults: For conditions manifested by agitation and anxiety (with or without depression), tension, excitation or irritability, 30–45 mg daily in divided doses.

For the treatment of severe psychosis in adults, up to 400 mg daily.

In elderly psychotics, daily doses of up to 150 mg in divided doses.

Dosage should be adjusted to the severity of the condition, beginning with a small dose and increasing it until the optimum level is reached, depending upon tolerance and effectiveness.

Children: If on the recommendation of a physician, a child's dosage is required the following is suggested as a guide.

Under 6 years: 1–2 mg/kg body weight daily.

Over 6 years: 15 mg three to four times daily.

Taractan Tablets are for oral administration.

Contra-indications, warnings, etc Precautions: With Taractan, as with other drugs acting on the central nervous system, patients should be instructed to avoid alcohol while under treatment, since the individual response cannot be foreseen. Like all medicaments of this type, Taractan may modify patients' reactions (driving ability, operation of machinery, etc) to a varying extent, depending on dosage and individual susceptibility. The established medical principle of prescribing medicaments in early pregnancy only when absolutely indicated should be observed.

Care should be taken in the use of anaesthetics, analgesics and hypnotics as their effects may be potentiated by Taractan.

In patients suspected to be suffering from cardiac insufficiency, with disturbances of heart rhythm or conduction, neuroleptics and tricyclic antidepressants should be administered with caution, especially in the elderly.

Particularly in predisposed subjects, the tricyclic antidepressants and neuroleptics may give rise to changes in the EEG: in rare cases, convulsions have been observed.

Side-effects: Taractan is relatively free from side-effects and toxic effects. It has a sedative action which can be useful in the treatment of many patients. Should sedation be too pronounced, it can be lessened by reducing the dose. Tachycardia and postural hypotension have occasionally been observed, but these have rarely been sufficiently serious to warrant discontinuation of the drug. Other side-effects reported in isolated cases are convulsions, constipation, dryness of the mouth and slight oedema. A very small number of cases of granulocytopenia have been reported in which the white cell count rapidly rose to normal after cessation of treatment.

Effects of overdosage and their treatment: The primary symptoms of overdosage are drowsiness, moderate to severe hypotension with shock, general weakness, cyanosis, pyrexia, contracted pupils, tachycardia, respiratory depression and coma. Convulsions may occur later.

Gastric lavage should be performed if soon after ingestion.

If hypotension occurs, the patient should be placed in a head-down position and oxygen and intravenous fluids administered. If an adequate blood pressure is not obtained, noradrenaline or metaraminol may be given, but not adrenaline. Respiration should be maintained by artificial methods. Intravenous Valium® Roche or short-acting barbiturates may be used to control convulsions.

Pharmaceutical precautions *Storage:* Taractan Tablets should be stored in well-closed containers.

Legal category POM.

Package quantities Taractan Tablets 15 mg in packings of 50.

Taractan Tablets 50 mg in packings of 50.

Further information Nil.

Tablets 50 mg 0031/5129

TEMETEX®

Presentation White cream containing 0.1% w/w diflucortolone valerate in an oil-in-water emulsion.

White to yellowish-white fatty ointment containing 0.1% w/w diflucortolone valerate in an anhydrous base.

White to yellowish-white ointment containing 0.1% w/w diflucortolone valerate in a water-in-oil emulsion.

Uses *Properties:* Diflucortolone valerate, the active ingredient of Temetex preparations, is a highly effective topical corticosteroid with rapid onset of action, marked anti-inflammatory action and good cutaneous tolerance. In addition to inhibiting inflammation in inflammatory and allergic skin diseases, it ameliorates the subjective complaints such as itching, burning and pain.

Three different presentations are available, each designed to suit a particular condition of the patient's skin, thereby aiding the achievement of the optimal clinical response.

Indications: Temetex preparations are indicated for the treatment of non-infected eczemas, dermatitis, psoriasis and other corticosteroid-responsive dermatoses.

Dosage and administration *Adults and children* Initially, the Temetex preparation best suited to the particular skin condition (see below) should be applied as a thin film two or three times daily according to the severity of the condition. Once clinical improvement has been obtained, maintenance treatment with one application daily should be sufficient.

Temetex cream is suitable for weeping skin lesions on moist skin regions (anus, flexures) which require a base with a high water-content. It allows secretions to drain and ensures rapid drying of the skin.

Temetex fatty ointment is designed for use in chronic and very dry or scaly conditions. The anhydrous, greasy base retains moisture thereby softening the thickened horny layer of the skin, and so improving the penetration of the active substance. As the fatty ointment has an occlusive effect, this largely dispenses with the need for occlusive dressings.

Temetex ointment has the broadest range of application: being suitable for conditions which are neither weeping nor very dry. The base, which has a balanced fat and water content, greases the skin lightly without having an occlusive effect.

In refractory cases either Temetex ointment or Temetex fatty ointment may be applied under an occlusive dressing large enough to cover completely the affected area of skin and affixed to healthy skin. The dressing should not be left on for more than two days but it may be replaced intermittently, if necessary. However, if the lesion becomes infected during treatment the use of occlusive dressings should be suspended until the infection has been controlled.

Temetex preparations are for external application only.

Contra-indications, warnings, etc

Contra-indications: Temetex should not be applied in the presence of syphilitic, tuberculous or viral (chicken pox, vaccinia) infections that involve the skin. It is not suitable for the treatment of ophthalmic conditions.

Temetex fatty ointment should not be applied to weeping lesions.

Precautions: With Temetex, as with all topical corticosteroid preparations, long-term continuous therapy in infants should be avoided as adrenal suppression can occur, even without the use of occlusive dressings. Babies and infants up to four years of age should not therefore be treated for a period of more than three weeks, especially in areas covered by napkins, which may act as an occlusive dressing.

Care should be taken to avoid contact with the eyes. The hands should be washed carefully after applying Temetex.

In pregnant animals topical application of corticosteroids can cause abnormalities of foetal development. The relevance of these findings to human beings has not been established. Nevertheless, topical corticosteroids should not be used extensively (i.e. in large amounts or for prolonged periods) during the first trimester of pregnancy.

Infections in the treated area require additional specific antimicrobial therapy. This treatment can often be topical, but for severe bacterial infections systemic therapy may be necessary. If fungal infections are present a topically active antimycotic agent should be applied.

side-effects: Temetex is well tolerated locally. Very occasionally a mild burning, itching or irritation may occur at the site of application.

As with all topical corticosteroids, there is a risk of skin atrophy, telangiectasia, striae and acneiform eruptions following extensive use of Temetex, particularly with the fatty ointment or where occlusive dressings are applied. The face is more susceptible to such atrophic changes than other areas of the body. The application of unusually large amounts of Temetex preparations may result in the absorption of systemically active amounts of corticosteroid.

In the event of any untoward reaction, treatment should be discontinued.

treatment of overdosage: It is anticipated that ingestion of Temetex preparations is unlikely to present any problems of management. No specific recommendations for treatment are made.

pharmaceutical precautions *Storage:* Recommended maximum storage temperature 30°C.

legal category POM.

package quantities Temetex cream, fatty ointment and ointment in tubes of 30 g.

ENSILON*

Presentation Ampoules containing 10 mg edrophonium chloride in 1 ml. The ampoule solution is almost colourless.

Uses Properties: Tensilon is an antagonist to cholinesterase, the enzyme which normally destroys acetylcholine. The action of Tensilon can briefly be described, therefore, as the potentiation of naturally occurring acetylcholine. It differs from Prostigmin* (neostigmine) and Mestinon* (pyridostigmine) in the rapidity and brevity of its action.

indications: Myasthenia gravis, as a diagnostic test; to distinguish between overdosage and underdosage of cholinergic drugs; diagnosis of suspected 'dual block'; treatment of paroxysmal supraventricular tachycardia; antidote to curariform drugs.

Dosage and administration *Adults - Test for myasthenia gravis:* A syringe is filled with the contents of 1 ampoule Tensilon (10 mg) and 2 mg is given intravenously, the needle and syringe being left *in situ*. If no reaction occurs within 30 seconds, the remaining 8 mg is injected. In adults with unsuitable veins, 10 mg is given by intramuscular injection.

To differentiate between 'myasthenic' and 'cholinergic' crises: In a myasthenic patient who is suffering from marked muscle weakness, in spite of taking large doses of Mestinon or Prostigmin, a test dose of 2 mg Tensilon is given intravenously one hour after the last dose of the cholinergic compound. If therapy has been adequate, there is a rapid, transient increase of muscle strength; if the patient has been overtreated, Tensilon causes a transient increase of muscle weakness.

Diagnosis of suspected 'dual block': Tensilon 10 mg intravenously. If the block is due to depolarisation, it is briefly potentiated, whereas in a 'dual block', it is reversed.

Treatment of paroxysmal tachycardia: Tensilon 10-20 mg intravenously, combined with carotid sinus pressure if necessary.

Antidote to curariform drugs: Tensilon 10 mg intravenously, repeated if necessary.

Children weighing up to 35 kg: 1 mg Tensilon intravenously or 2 mg intramuscularly.

Weighting more than 35 kg: 2 mg Tensilon intravenously or 5 mg intramuscularly.

Tensilon Ampoules are for intramuscular or intravenous injection.

Tensilon Ampoule solution may be diluted with Water for Injection.

Maintenance of stability cannot be guaranteed when Tensilon Ampoule solution is diluted.

Contra-indications, warnings, etc *Precautions:* Care should be taken in administering Tensilon to patients with bronchial asthma.

A syringe containing 1 mg of atropine should be kept at hand to counteract severe cholinergic reactions, should they occur.

Side-effects: These may include nausea and vomiting, increased salivation, diarrhoea and abdominal cramps.

Effects of overdosage and their treatment: Tensilon overdosage may give rise to bradycardia, arrhythmias, hypotension and bronchiolar spasm. Perspiration, gastro-intestinal hypermotility and visual disturbances may also occur.

Atropine sulphate 1-2 mg intravenously is an antidote to the muscarinic effects.

Pharmaceutical precautions *Storage:* Tensilon Ampoule solution should be protected from light.

Legal category POM.

Package quantities Tensilon Ampoules in packings of 10.

Further information Nil.

Product licence number 0031/5095.

TIGASON* ▼

Presentation Capsules with buff-yellow cap and buff-yellow body with ROCHE printed in black on both cap and body, containing 10 mg tretinate.

Capsules with orange-yellow cap and buff-yellow body with ROCHE printed in black on both cap and body, containing 25 mg tretinate.

Uses Properties: Retinol (vitamin A) is known to be essential for normal epithelial growth and differentiation, though the mode of this effect is not yet established.

Both retinol and retinoic acid are capable of reversing hyperkeratotic and metaplastic skin changes. However, these effects are generally only obtained at dosages associated with considerable local or systemic toxicity.

Tigason, a synthetic aromatic derivative of retinoic acid, has a more favourable therapeutic ratio, with a greater and more specific inhibitory effect on psoriasis and disorders of epithelial keratinization. The usual therapeutic response to Tigason consists of desquama-

tion (with or without erythema) followed by more normal re-epithelization.

Indications: Severe extensive psoriasis which is resistant to other forms of therapy.

Palmo-plantar pustular psoriasis.
Congenital ichthyosis.

Dosage and administration There is a wide variation in the absorption and rate of metabolism of Tigason. This necessitates individual adjustment of dosage. For this reason the following dosage recommendations can serve only as a guide.

Adults: Other dermatological therapy, particularly with keratolytics, should normally be stopped before administration of Tigason, though use of topical corticosteroids or bland emollient ointment may be continued if indicated.

Tigason should be started at a dose of 0.75–1 mg/kg body-weight per day (in most cases 50–75 mg daily), taken in divided doses, for two to four weeks. By this time involved areas of skin will usually show a marked response and/or side-effects should be apparent. If no therapeutic effect is seen by four weeks, and in the absence of toxicity, daily dosage may then be increased in increments of 10 mg at weekly intervals until a response is observed or a total daily dose of 1.5 mg/kg body-weight is reached.

Once a response has been observed, the dosage of Tigason should be reduced to 0.5 mg/kg body-weight per day, taken in divided doses, for a further six to eight weeks, when the maximum therapeutic effect should usually have been obtained.

In patients with psoriasis, Tigason is normally discontinued when the lesions have shown maximum clearing. Further exacerbations may be treated in the same way as and when they occur. In other conditions, continued maintenance therapy, at the lowest dose which will prevent recurrences (usually 0.25–0.5 mg/kg body-weight per day), may be appropriate.

Elderly: Dosage is the same as for adults.

Children: Dosage should be carried out as outlined above for adults. Clinical experience indicates that Tigason is generally better tolerated by children.

Tigason capsules are for oral administration.

Contra-indications, warnings, etc *Contra-indications:* Tigason is teratogenic. Therefore, in any woman of childbearing potential, the risk must be weighed against the expected therapeutic benefit under all circumstances, taking into account the precautions specified below.

Tigason is contra-indicated in patients with hepatic or renal impairment.

Precautions: For all women of childbearing potential the following precautions must be strictly observed.

1. Any woman of childbearing potential who is receiving Tigason must practise long-term, effective contraception, not only during the treatment period but also for at least 12 months following its cessation.

2. The same contraceptive measures must also be taken in the case of repeated treatment for recurrences of the disease.

3. Any pregnancy occurring during treatment with Tigason, or in the 12 months following its completion, carries a high risk of foetal malformation. This would raise the question of the termination of pregnancy for medical reasons. Therefore, before instituting Tigason the treating physician must explain clearly and in detail

what precautions must be taken. This should include the risks involved and the possible consequences of a pregnancy occurring during Tigason treatment or in the 12 months following its completion.

In view of the importance of the above precautions Tigason Patient Information Cards are available to doctors and it is strongly recommended that these be given to all patients.

It is recommended that liver function tests be carried out after one month of treatment and at three-monthly intervals thereafter.

Blood lipids should be monitored at similar intervals in patients who may be predisposed to hypertriglyceridaemia, especially those with a history of type IV hyperlipidaemia, alcohol abuse, obesity and diabetes mellitus.

Patients should be warned of the possibility of alopecia occurring (see 'Side-effects').

Patients should also be instructed to avoid taking preparations containing high doses of Vitamin A, i.e. more than the recommended dietary allowance of 4,000–5,000 iu per day.

Side-effects: The toxic dose of Tigason is close to the therapeutic dose and most patients experience some side-effects during the initial period whilst dosage is being adjusted. These side-effects are generally minor and acceptable to patients. They have proved reversible with reduction of dosage or discontinuation of therapy.

They commonly consist of dryness, sometimes with erosion, of mucous membranes, especially the lips, nose and conjunctivae; desquamation, erythema, thinning and pruritus, rarely burning, of non-involved skin areas; exfoliation of palmar and plantar skin; paronychia. A bland emollient or topical corticosteroid may be prescribed to alleviate the cutaneous inflammation.

Excess hair loss is common and frank alopecia may occur. This is manifested later than other side-effects from four to eight weeks after starting therapy. Normal hair growth resumes from two to twelve weeks after completion of therapy.

Elevation of serum levels of liver transaminases and bilirubin outside the normal range has been observed in a small percentage of patients whilst receiving Tigason. If hepatotoxicity is suspected in any patient, therapy should be discontinued immediately.

Elevation of serum triglyceride levels above the normal range has been reported to occur in some patients, especially those with a predisposition to hypertriglyceridaemia. The changes are dose-related and reversible and may be controlled by dietary means alone in some cases.

Nausea, headache, drowsiness, sweating and anorexia have been reported infrequently.

Treatment of overdosage: Manifestations of acute vitamin A toxicity include severe headache, nausea or vomiting, drowsiness, irritability and pruritus. Signs and symptoms of accidental or deliberate overdosage with Tigason would probably be similar. They would be expected to be reversible and to subside without need for treatment.

Because of the variable absorption of the drug, gastric lavage may be worthwhile within the first few hours after ingestion.

Pharmaceutical precautions *Storage:* Tigason capsules should be stored in a well-closed container and protected from light. The recommended maximum storage temperature is 30°C.

Legal category POM.

Package quantities Tigason capsules 10 mg in packings of 100.

Tigason capsules 25 mg in packings of 100.

Further information *Availability:* Tigason capsules are available only through hospital pharmacies for use in hospitals and hospital clinics.

It is recommended that Tigason be given only by, or under supervision of, a dermatological specialist.

Product licence numbers

Capsules 10 mg 0031/0134

Capsules 25 mg 0031/0135.

TRH-ROCHE

Approved name: Protirelin.

Presentation Plain glass ampoules containing 0.2 mg TRH-Roche (thyrotrophin-releasing hormone) in 2 ml. The ampoule solution is almost colourless to faintly yellow.

Round, white tablets with 'ROCHE' imprinted on one face and a single break bar on the other and imprinted 'TRH' containing 40 mg TRH-Roche (thyrotrophin-releasing hormone).

'TRH'

Uses *Properties:* TRH-Roche stimulates the secretion of thyroid-stimulating hormone (TSH). Intravenous injection results in a prompt rise in serum TSH levels in normal subjects, peak levels being observed about 20 minutes after administration. There is a concomitant rise in serum levels of prolactin. TRH-Roche is also active orally, the maximum TSH response being apparent some two to four hours after ingestion. The maximum responses of protein-bound iodine (PBI), tri-iodothyronine (T_3) and thyroxine (T_4) occur up to five hours after the administration of a single oral dose.

Indications: The administration of TRH-Roche provides a means of assessing thyroid function and the reserve of TSH in the pituitary gland and is recommended as a test procedure where such assessment is indicated. It is particularly useful as a diagnostic test for: mild hyperthyroidism; ophthalmic Graves' disease; mild or preclinical hypothyroidism; hypopituitarism; hypothalamic disease. It may also be used in place of the T_3 suppression test.

Dosage and administration *Intravenous injection:* Tests employing intravenous TRH-Roche are based on the serum TSH response to a standard dose. They provide a means of both quantitative and qualitative assessment of thyroid function. It is essential for each laboratory to establish its own normal range of values for serum TSH before attempting quantitative assessment of TRH-Roche responses by this means.

Intravenous TRH-Roche test:

1. Blood sample taken for control TSH assay.
2. TRH-Roche 0.2 mg given as a single bolus injection.
3. Blood sample taken 20 minutes after injection for peak TSH assay.
4. If necessary, a further blood sample may be taken 60 minutes after injection to detect a delayed TSH response.

The ampoule solution should not be diluted.

Oral TRH-Roche test: Responses to oral TRH-Roche have not been defined within precise limits and they therefore provide a means of qualitative rather than quantitative assessment.

1. Blood sample taken either immediately before TRH-Roche administration or, if more convenient, on the previous day for control TSH assay and/or PBI, T_3 or T_4 estimations.

2. TRH-Roche 40 mg (1 tablet) administered with half a glass of water to the patient fasted overnight.

3. Patient to fast for one hour after taking the tablet.

4. Blood sample taken four to five hours after dosing for repeat estimations of TSH and/or PBI, T_3 or T_4 .

TRH-Roche tablets are for oral administration.

The procedures for administering TRH-Roche to children are identical with those outlined above.

Interpretation of results: Interpretation of the responses to TRH-Roche is based on the increase in TSH and/or PBI, T_3 or T_4 levels from the basal values. In normal subjects, there is a prompt rise in serum levels of TSH. The changes observed in various conditions are briefly outlined below:

1. Hyperthyroidism – no rise in serum TSH or thyroid hormone levels.

2. Ophthalmic Graves' disease – often no rise in serum TSH or thyroid hormone levels.

3. Primary hypothyroidism – exaggerated and prolonged rise in serum TSH but no change in thyroid hormone levels.

4. Hypopituitarism – absent or impaired TSH or thyroid hormone response implies diminished TSH reserve.

5. Hypothalamic disease – a rise in serum TSH or thyroid hormone levels can occur in the presence of hypothyroidism; delayed responses are common.

The TRH-Roche test provides, in most instances, information similar to that obtained from a T_3 suppression test in that an absent or impaired response usually correlates with an absent or impaired response to T_3 suppression.

The response to TRH-Roche may be modified in subjects taking T_3 , T_4 , antithyroid drugs, corticosteroids, oestrogens, theophylline or levodopa.

Contra-indications, warnings, etc *Precautions:*

There are no absolute contra-indications to TRH-Roche. In view of the postulated effect of bolus injections of TRH-Roche on smooth muscle, administration orally would seem more appropriate in patients with bronchial asthma or other types of obstructive airways disease. Caution should also be observed in patients with myocardial ischaemia. TRH-Roche administration is not normally associated with a fall in blood sugar, but caution is recommended when giving the drug orally to patients with severe hypopituitary disease in the fasting state because of the possibility of hypoglycaemia.

Teratogenic effects have not been demonstrated in animal experiments. Nevertheless, the established medical principle of not administering drugs during early pregnancy should be observed.

Side-effects: TRH-Roche is well tolerated. No impairment of hepatic, renal or haematological function has been reported and the drug has no effect on pulse rate, blood pressure or respiration. Following rapid intravenous injection, side-effects of a mild and transient nature may be experienced. They comprise nausea, a desire to micturate, a feeling of flushing, slight dizziness and a peculiar taste, and have been attributed to a local action of the bolus of TRH-Roche on the plain muscle of the gastro-intestinal and genito-urinary tracts. Side-effects after oral administration are very rare, nausea

being the only one so far observed. No reactions of an allergic nature have been noted with TRH-Roche.

Effects of overdosage: No symptoms of overdosage have been noted in patients receiving up to 1 mg intravenously.

Pharmaceutical precautions *Storage:* The recommended maximum storage temperature for TRH-Roche Ampoules is 30°C. No special precautions are required for the Tablets.

Legal category POM.

Package quantities TRH-Roche Ampoules containing 0.2 mg TRH-Roche in 2 ml in packings of 10. TRH-Roche 40 mg Tablets in packings of 10.

Further information *Availability:* TRH-Roche is available to hospitals only.

VALIUM® ROCHE

Presentation Round, white tablets with 'ROCHE 2' imprinted on one face and a single break bar on the other, containing 2 mg diazepam.

Round, pale yellow tablets with 'ROCHE 5' imprinted on one face and a single break bar on the other, containing 5 mg diazepam.

Round, blue tablets with 'ROCHE 10' imprinted on one face and a single break bar on the other, containing 10 mg diazepam.

Capsules with opaque, blue cap and opaque, white body with 'ROCHE 2' printed in red-brown along both cap and body, containing 2 mg diazepam.

Capsules with opaque, blue cap and opaque, yellow body with 'ROCHE 5' printed in red-brown along both cap and body, containing 5 mg diazepam.

Pink, raspberry-flavoured syrup containing 2 mg diazepam in 5 ml.

Ampoules containing 10 mg diazepam in 2 ml. The ampoule solution is almost colourless to greenish-yellow.

Ampoules containing 20 mg diazepam in 4 ml. The ampoule solution is almost colourless to greenish-yellow.

Suppositories containing 5 mg diazepam.

Suppositories containing 10 mg diazepam.

Uses *Properties:* Valium Roche has potent anxiolytic, anticonvulsant and central muscle-relaxant properties. These effects are probably mediated through special areas of the central nervous system, such as the limbic system, the reticular activating system and the polysynaptic pathways.

Valium Roche has little autonomic activity.

Indications: *Tablets, Capsules, Syrup and Suppositories:* Anxiety and tension states; insomnia associated with anxiety; psychosomatic and organic illness with associated anxiety and physical tension; tension headache; psychoses accompanied by anxiety; muscle spasm; control of muscle spasm in tetanus (also i.v.); as premedication for the nervous dental patient; epilepsy.

Ampoules: Severe acute anxiety and agitation including delirium tremens, acute muscle spasm; tetanus; status epilepticus and convulsions due to poisoning. As intravenous sedative cover before and during minor surgical procedures in obstetrics, surgery, dentistry, ophthalmology, endoscopy, radiology, cardiac catheterisation and cardioversion.

Dosage and administration *Tablets, Capsules, Syrup and Suppositories:* Acute and chronic anxiety states:

Adults: Mild anxiety in ambulant patients – 2 mg three times daily.

Severe anxiety states and obsessive-compulsive neurosis – 15–30 mg daily in divided doses. In severe cases being treated in hospital, 10 mg i.m. may be given and can be repeated after an interval of not less than four hours.

Insomnia associated with anxiety – 5–30 mg before retiring.

Children: 1–5 mg daily in divided doses.

Conditions associated with muscle spasm:

Spastic children with minimal brain damage – 2–40 mg daily in divided doses.

Cerebral palsy of adults particularly associated with athetoid movements – 2–60 mg daily in divided doses.

Upper motor neurone spasticity – 5–60 mg daily in divided doses.

Muscle spasm of varied aetiology, fibrositis, cervical spondylosis – 2–15 mg daily in divided doses.

As oral pre-medication in dental patients – 5 mg the night before, 5 mg on waking and a further 5 mg two hours before the appointment.

Elderly and debilitated patients; doses should be half those recommended for other adults.

Valium Roche Tablets. Capsules and Syrup are for oral administration.

Valium Roche Suppositories are for rectal administration.

Valium Roche Syrup may be diluted with Sorbitol solution BPC or Syrup BP.

Ampoules: Acute muscle spasm, acute anxiety or agitation – 10 mg by i.v. or i.m. injection which can be repeated after an interval of not less than four hours.

As intravenous sedative cover before and during dental surgery and other unpleasant surgical and medical procedures – the dose is governed by the response of the patient. As a guide 0.2 mg/kg body weight is suggested. Total dose usually varies between 10 to 20 mg, but more than 20 mg may be necessary on occasions.

Tetanus – Initially an i.v. dose of 0.1–0.3 mg/kg body weight, repeated at intervals of one to four hours. Continuous i.v. infusion of 3–10 mg/kg body weight/24 hours can also be used as well as identical daily doses by nasoduodenal tube. The dose should be adapted according to the severity of the case, and in extremely severe cases higher doses have been used.

Status epilepticus – Convulsions due to poisoning – *Adults:* 10 to 20 mg IV or IM. *Children:* 0.2 to 0.3 mg/kg body-weight IV or IM, or 1 mg per year of life. These doses may be repeated, as necessary, thirty minutes or one hour later. If required this may be followed by intravenous infusions (maximum dose: 3 mg/kg body-weight over 24 hours).

Febrile convulsions – 0.2 to 0.3 mg/kg body-weight IV or IM, or 1 mg per year of life. These doses may be repeated as necessary.

Elderly and debilitated patients: doses should be half those recommended for other adults.

Intravenous injection may be associated with local reactions, including thrombophlebitis. In order to reduce the likelihood of untoward effects, it is strongly recommended that intravenous injections of Valium Roche should be given into a large vein of the antecubital fossa, the patient having been placed in the supine position and kept there throughout the procedure.

The injection should be given **slowly** (0.5 ml of the

solution per half-minute) until the patient becomes drowsy, his eyelids droop and his speech becomes slurred, but he is still able to respond to requests. If these conditions for administration of Valium Roche intravenously are adhered to the rare possibility of hypotension or apnoea occurring will be greatly diminished. It is suggested that a second person should be present during this procedure and that facilities for resuscitation should always be available. It is recommended that the patient should not be allowed to leave the surgery until one hour at least has elapsed from the time of injection and should always be accompanied by a responsible adult, with a warning not to drive or to operate machinery for the rest of the day.

Valium Roche Ampoule solution should **not** be diluted. One exception to this is when given slowly in large intravenous infusions of normal saline or glucose, such as are given in the treatment of tetanus and status epilepticus. Then up to 40 mg – 8 ml Ampoule solution – in 500 ml is permissible. This infusion dilution should be made up freshly and used within six hours.

Valium Roche Ampoule solution should **not** be mixed with other drugs in the same infusion solution or in the same syringe.

Maintenance of stability cannot be guaranteed if these rules are not obeyed.

Contra-indications, warnings, etc *Precautions:* With Valium Roche, as with other drugs acting on the central nervous system, patients should be instructed to avoid alcohol while under treatment, since the individual response cannot be foreseen. Like all medicaments of this type, Valium Roche may modify patients' reactions (driving ability, operation of machinery, etc) to a varying extent, depending on dosage, administration and individual susceptibility. Similarly, as with many drugs, dosage of Valium Roche must be adapted to the widely varying limits of tolerance encountered in patients with organic cerebral changes (particularly arteriosclerosis) or with cardiorespiratory insufficiency. In these patients parenteral administration should not as a rule be employed. However, Valium Roche may be given parenterally to such patients when treated in hospital, or in an emergency; in the case of i.v. administration the dosage should then be reduced and the injection given slowly.

The use of high doses of benzodiazepines, especially over prolonged periods, may sometimes lead to dependence, particularly in patients with a history of alcoholism or drug abuse. Treatment in these cases should be withdrawn gradually.

Results obtained in trials with several generations of mice, rats, rabbits and dogs indicate that no danger of teratogenic effects need be expected from therapeutic doses of Valium Roche. Nevertheless the established medical principle of prescribing medicaments in early pregnancy only when absolutely indicated should be observed.

If Valium Roche is combined with centrally acting drugs such as neuroleptics, tranquillisers, antidepressants, hypnotics, analgesics and anaesthetics, it should be borne in mind that their sedative effect may be intensified by Valium Roche. In particular, the possibility of severe respiratory and cardiovascular depression should be considered if central depressant drugs are given parenterally in conjunction with intravenous Valium Roche.

Side-effects: Valium Roche is well tolerated and the occurrence of ataxia is evidence of excessive dosage.

When high doses are used they may also have a sedative effect and cause some degree of drowsiness. In such cases there is an advantage in administering half the total daily intake at night, the remainder being given in divided doses during the day.

Effects of overdosage and their treatment: Reported experience of inadvertent or deliberate overdosage indicates that this presents virtually no problem. Doses of up to approximately 2 g Valium Roche taken alone during attempted suicide have produced no long-term ill-effects.

Symptoms of overdosage may include drowsiness, ataxia and dysarthria, with coma in very severe cases. Treatment is symptomatic, but gastric lavage may be useful if performed soon after ingestion.

Pharmaceutical precautions *Storage:* The recommended maximum storage temperature for Valium Roche Syrup and Ampoules is 30°C. Valium Roche Suppositories should be protected from heat. The oral and parenteral forms should be protected from light.

Legal category POM.

Package quantities

Valium 2 Roche

Tablets 2 mg in packings of 100 and 500. Capsules 2 mg in packings of 100 and 500. Syrup 2 mg/5 ml in packings of 100 ml.

Valium 5 Roche

Tablets 5 mg in packings of 100 and 500. Capsules 5 mg in packings of 100 and 500.

Valium 10 Roche

Tablets 10 mg in packings of 100 and 500. Ampoules 10 mg in 2 ml in packings of 10.

Valium 20 Roche

Ampoules 20 mg in 4 ml in packings of 10.

Valium Roche Suppositories 5 mg and 10 mg in packings of 5.

Further information As with a number of other medicaments, intramuscular injection of Valium Roche (but not oral or intravenous administration) can lead to a rise in serum creatine phosphokinase activity, with a maximum between 12 and 24 hours after the injection. This fact should be taken into account in the differential diagnosis of myocardial infarction.

VALRELEASE* ▼

Presentation Capsules with opaque blue cap and opaque light blue body with ROCHE printed in red along both cap and body, containing 10 mg diazepam in a controlled-release form.

Uses *Properties:* Valrelease has the characteristics of the benzodiazepine tranquillizers. The active ingredient, diazepam, is released in a controlled manner thus

avoiding the peaks and troughs in plasma levels which are encountered with conventional three-times daily administration.

Indications: Treatment of the symptoms of anxiety – this includes both psychic and somatic manifestations.

Dosage and administration *Adults:* One capsule daily to be taken usually early in the evening. No dosage recommendations are made for elderly patients.

Children: No dosage recommendations are made for children.

Valrelease capsules are for oral administration.

Valrelease capsules should be taken with water.

Contra-indications, warnings, etc *Contra-indications:* Patients with known sensitivity to benzodiazepines; acute pulmonary insufficiency; respiratory depression.

Precautions: In patients with chronic pulmonary insufficiency, and in patients with chronic renal or hepatic disease, dosage may need to be modified.

The use of diazepam during pregnancy should be avoided unless there are compelling reasons for administration.

Diazepam crosses the placenta and the administration of high doses or prolonged administration of low doses in the last trimester of pregnancy or labour has been reported to produce irregularities in the foetal heart, and hypotonia, poor sucking and hypothermia in the neonate.

Diazepam has been detected in breast milk. If possible, the use of Valrelease should be avoided during lactation.

If diazepam is combined with centrally-acting drugs such as neuroleptics, tranquillizers, antidepressants, hypnotics, analgesics and anaesthetics, the sedative effects may be intensified.

Patients should be advised that, like all medicaments of this type, diazepam may modify patients' performance at skilled tasks (driving, operating machinery, etc.) to a varying degree depending upon dosage, administration and individual susceptibility. Patients should further be advised that alcohol may intensify any impairment, and should therefore be avoided during treatment.

The dependence potential of the benzodiazepines is low but this increases when high doses are used, especially when given over long periods. This is particularly so in patients with a history of alcoholism or drug abuse or in patients with marked personality disorders. Regular monitoring in such patients is essential and routine repeat prescriptions should be avoided. Treat-

ment should be withdrawn gradually. Symptoms such as depression, nervousness, rebound insomnia, irritability, sweating, and diarrhoea have been reported following abrupt cessation of treatment with normal therapeutic doses.

In rare instances, withdrawal following excessive dosages may produce confusional states, psychotic manifestations and convulsions.

Abnormal psychological reactions to benzodiazepines have been reported. Rare behavioural effects include paradoxical aggressive outbursts, excitement, confusion, and the uncovering of depression with suicidal tendencies.

Side-effects: Common adverse effects include drowsiness, sedation, unsteadiness and ataxia; these are dose-related and may persist into the following day even after a single dose.

Other adverse effects are rare and include headache, vertigo, hypotension, gastro-intestinal upsets, skin rashes, visual disturbances, changes in libido, and urinary retention. Isolated cases of blood dyscrasias and jaundice have also been reported.

Treatment of overdose: When taken in overdose, diazepam presents few problems in management. Signs may include drowsiness, ataxia and dysarthria, with coma in severe cases. Treatment is symptomatic. Gastric lavage is useful only if performed soon after ingestion. There is no specific antidote to diazepam.

When taken with centrally-acting drugs, especially alcohol, the effects of overdose are likely to be more severe and, in the absence of supportive measures, may prove fatal.

Pharmaceutical precautions *Storage:* Valrelease capsules should be protected from light and stored in a dry place. Recommended maximum storage temperature is 30°C.

Legal category POM.

Package quantities Valrelease capsules 10 mg in packings of 50.

Further information Nil.

ARGOTONE*

Presentation Brown liquid containing the following active ingredients:

Ephedrine Hydrochloride BP	0.9%
Mild Silver Protein BPC 1968	1.0%

Uses Nasal decongestant.

Dosage and administration *Argotone Nasal Drops:* 4–6 drops in each nostril three to five times daily.

Argotone Ready Spray: 2–3 sprays in each nostril four to five times daily.

Contra-indications, warnings, etc As with all sympathomimetic amines: prolonged use may cause rebound congestion, although we have not received reports of this caused by Argotone; concurrent administration with monoamine oxidase inhibitors is contra-indicated.

Side-effects: Either incorrect or excessive usage could cause skin discolouration.

Overdosage – Signs and Symptoms: Argyria – a bluish-black discolouration of the skin would indicate ingestion. The signs and symptoms of toxicity would be those of ephedrine over-dosage. Features such as anxiety, insomnia, irritability, giddiness, headache, nausea and vomiting, palpitations, tachycardia, hypertension, difficulty in micturition may occur. In very large doses paranoid psychosis and hallucinations may be prominent. Theoretically in excessive use sufficient ephedrine could be absorbed via the nasal mucosa, particularly in infants who could then exhibit some of these symptoms. We have received no such reports.

Overdosage – Treatment: Since severe overdosage is considered to be so unlikely, treatment should consist mainly of careful monitoring of the patient, particularly respiration and circulation. Methods directed at prevention of further absorption of the ingredients such as emesis or gastric lavage generally are considered inappropriate.

Pharmaceutical precautions It should be protected from light.

Legal category P.

Package quantities *Argotone Nasal Drops:* Glass bottle containing 20 ml. Plastic container of 100 ml for dispensing.

Argotone Ready Spray: Plastic atomiser containing 15 ml.

Further information Rapid effect against all organisms commonly infecting the nasopharynx. No inhibitory effect on nasal cilia. Relieves congestion of mucous membranes.

Product licence number 0161/5005.

DILORAN*

Presentation *Suspension:* Each 10 ml of white, peppermint-flavoured suspension contains:

Magnesium Oxide	320 mg
Aluminium hydroxide/Magnesium carbonate co-dried gel	80 mg
Activated dimethicone	25 mg

Tablets: White, flat tablets, 13 mm in diameter, with a bevelled edge, marked 'Diloran' on each face. Each spearmint-flavoured tablet contains:

Magnesium Oxide	340 mg
Aluminium hydroxide/Magnesium carbonate co-dried gel	85 mg
Activated dimethicone	25 mg

Uses For the relief of dyspeptic symptoms in those conditions where an antacid/antiflatulent preparation is indicated, for example dyspepsia of functional or organic origin, hyperacidity, hiatus hernia, indigestion, oesophagitis, gastritis, and the symptomatic treatment of peptic ulcer.

Dosage and administration For oral administration.

Suspension: Adults: Two to four 5 ml spoonful three times a day between meals and at bedtime, or as required.

Children (5–12 years): One or two 5 ml spoonful three times daily between meals and at bedtime.

Infants (under 5 years): Half to one 5 ml spoonful four times a day.

Tablets: Adults: 1–2 tablets chewed or sucked three times daily between meals and at bedtime, or as required.

Children (5–12 years): 1 tablet chewed or sucked three times daily between meals and at bedtime.

Infants (under 5 years): The dosage form of Diloran Suspension is more adaptable for this age group and is therefore more suitable than tablets.

Contra-indications, warnings, etc As with other antacids care is necessary in hypophosphataemia, renal failure, debilitated states and during the first trimester of pregnancy unless compelling reasons for use. Aluminium hydroxide may also form complexes with tetracyclines and reduce absorption when given concomitantly.

Overdosage – Signs and Symptoms: There is little or no absorption of magnesium and aluminium ions (except in patients with renal failure), and therefore, this is not considered a problem. In very large doses the remaining magnesium ions (which have not been formed into the relatively insoluble carbonate in the intestine) may result in diarrhoea. Aluminium ions form an insoluble salt with phosphate in the intestine leading to a loss of phosphate which should be considered in overdosage situations.

Overdosage – Treatment: Symptomatic. Monitor patients particularly in relation to plasma phosphate levels.

Pharmaceutical precautions No special storage requirements.

Legal category P.

Package quantities *Suspension*: Bottles of 300 ml.
Tablets: Packs of 30.

Further information Diloran is a well-balanced preparation combining three well-accepted insoluble antacids with activated dimethicone. Diloran provides prompt and effective control of gastric acidity, together with a demulcent and antifatulent effect.

The combination of magnesium and aluminium salts means that there is little likelihood of either diarrhoea or constipation.

Diloran Tablets 0161/0013

GLUCOPHAGE*

Presentation White, film-coated tablets, marked 'GLUCOPHAGE 500', containing 500 mg Metformin Hydrochloride BP.

White, film-coated tablets, marked 'GLUCOPHAGE 850', containing 850 mg Metformin Hydrochloride BP.

Uses Diet-failed non-insulin dependent diabetic patients, especially if overweight: alone as initial therapy; in combination with a sulphonylurea. Occasionally as adjuvant therapy in insulin-dependent diabetic patients who are usually obese and not well controlled with insulin.

Dosage and administration It is important that Glucophage tablets should be taken in divided doses with meals. The dose should be increased gradually. One 850 mg tablet twice a day or one 500 mg tablet three times a day is often enough to give good diabetic control. This may be achieved within a few days, but it is not unusual for the full effect to be delayed for up to two weeks. If control is incomplete a cautious increase in dosage to a maximum of 3 g daily is justified. Once control has been obtained it may be possible to reduce the dosage.

Contra-indications, warnings, etc

Contra-indications: Diabetic coma and ketoacidosis. Impairment of renal function. Chronic liver disease. Cardiac failure. Recent myocardial infarction. Alcoholism (acute or chronic). Conditions associated with hypoxaemia. States associated with lactic acidosis such as shock or pulmonary insufficiency. History of lactic acidosis.

Precautions: Glucophage is excreted by the kidney and care is consequently necessary in patients with decreased renal function. This may be particularly relevant in very elderly patients.

The use of Glucophage is not advised: in pregnancy, unless there are compelling reasons for its use; in conditions which may cause dehydration; in patients suffering from serious infections or trauma, and in those undergoing surgery and certain investigations such as intravenous urography and intravenous angiography. Glucophage therapy should be stopped 2-3 days before these events and be reinstated only after control of renal function.

It is prudent to stop Glucophage therapy temporarily if any of the above conditions exist, particularly if gastro-

intestinal disturbances are noted or acidosis is suspected. After ketoacidosis and lactic acidosis have been excluded Glucophage treatment may be resumed if renal function is not impaired.

Patients receiving continuous metformin therapy should have an annual estimation of B_{12} in view of reports of decreased B_{12} absorption.

Glucophage therapy with a sulphonylurea or insulin should be monitored by blood-sugar readings because combined therapy may cause hypoglycaemia. If it is decided to stabilise diabetic patients with Glucophage and insulin therapy it is recommended that this is carried out in hospital because of the possibility of hypoglycaemia until the correct ratio of the two drugs is determined.

As with a number of drugs interaction between Glucophage and anticoagulants is a possibility. Thus patients receiving the two drugs may need adjustment of the anticoagulant dosage.

Side effects: Glucophage is well tolerated but gastrointestinal upsets which are usually minor and transient are often avoided by taking Glucophage with meals (which is always recommended). Occasionally a temporary lowering of the dose may be needed. Only 3% of patients have to discontinue Glucophage therapy because of this complication. Therefore, it is important that treatment is not abandoned at the first sign of intolerance since this has been found to resolve spontaneously, and it is usual for gastro-intestinal upsets to disappear within the period during which diabetic control is achieved. It is unusual for them to return and if such symptoms occur an alternative reason should be sought.

Adverse reactions: Lactic acidosis is a serious and often fatal metabolic complication which has been reported in a number of diseases including diabetes. It is characterised by acidosis (decreased blood pH); electrolyte disturbances with an increased anion gap and an increased lactate level with altered lactate/pyruvate ratio. Azotaemia may also be present. Lactic acidosis often has an insidious onset and non-specific symptomatology. Marked anorexia or unexplained weight loss may indicate the onset and precede the full clinical manifestations of lactic acidosis presenting with nausea, vomiting, hyperventilation, malaise and/or abdominal pain. In the majority of fatal cases patients with these early symptoms have not been investigated for lactic acidosis. In patients with a metabolic acidosis lacking evidence of ketoacidosis (ketonuria and ketonaemia) lactic acidosis should be suspected. Lactic acidosis is a medical emergency which must be treated in hospital immediately.

Certain cases of lactic acidosis reported with Glucophage therapy have occurred in patients with complications included in the contra-indications. The problem of lactic acidosis with Glucophage is negligible provided that patients are correctly selected and attention paid to the correct diet and dosage.

Glucophage may be secreted into breast milk but amounts are considered to be negligible.

Overdosage - Signs and Symptoms: Hypoglycaemia is not normally a problem encountered with Glucophage when used alone (fifty tablets have been ingested with no untoward effects on blood sugar). In combination therapy with a sulphonylurea or insulin or with alcohol hypoglycaemia can occur.

In excessive dosage and particularly if there is a possibility of accumulation lactic acidosis should be suspected. Some of the signs and symptoms suggestive

f this condition are nausea, diarrhoea, abdominal pain, dyspnoea.

Overdosage – Treatment: Intensive supportive therapy is recommended which should be particularly directed at correcting fluid loss and metabolic disturbance.

Pharmaceutical precautions No special storage requirements.

Legal category POM.

Package quantities *850 mg:* Securitainers containing 10 or 300 tablets.
100 mg: Securitainers containing 100 or 500 tablets.

Further information Glucophage does not lower blood-sugar levels in non-diabetics, and in diabetics does not cause hypoglycaemia when used alone. (In combination with other antidiabetic agents hypoglycaemia may occur – see above). Weight is reduced and elevated levels of plasma cholesterol, triglycerides and pre-beta-lipoproteins are lowered. Glucophage improves peripheral glucose metabolism.

500 mg 0161/5006

350 mg 0161/5007

HEPACORT PLUS*

Presentation *Cream:* A white, percutaneous cream containing in each 10 g tube the following active ingredients:

Heparin Sodium	10,000 units
Hydrocortisone Acetate BP	10 mg

Suppositories: White suppositories each containing the following active ingredients:

Heparin Sodium	2,000 units
Hydrocortisone Acetate BP	2 mg

Uses *Cream:* Eczematous conditions, varicose eczema, superficial phlebitis and pruritus vulvae.

Suppositories: Haemorrhoids, proctitis, anal eczema and pruritus.

Dosage and administration *Cream:* Massage gently into the affected area three times daily.

Suppositories: Insert 1 suppository into the rectum two or three times daily.

Contra-indications, warnings, etc Viral diseases of the skin, especially herpes simplex. Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established; however, topical corticosteroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

In infants, long-term continuous topical therapy should be avoided. Adrenal suppression can occur, even without occlusion.

Precautions: Local infective conditions may require additional specific antimicrobial or antifungal therapy either topical or systemic.

Side-effects: Excessive use of suppositories could in theory cause rectal bleeding. Removal of suppositories should be sufficient treatment.

Overdosage: Ingestion of either Hepacort cream or suppositories is considered unlikely to produce any

untoward symptoms. Heparin is orally inactive and the low hydrocortisone content is considered insufficient to cause systemic absorption to a problematic degree with the amounts that are likely to be ingested.

Pharmaceutical precautions For the storage of suppositories high temperatures should be avoided.

Legal category POM.

Package quantities *Cream:* Tube containing 10 g percutaneous cream.

Suppositories: Boxes containing a tray of 6 suppositories.

Further information Effectively combines advantages of local hydrocortisone with local heparin. Side-effects minimised by low hydrocortisone content.

Cream 0161/5008

Suppositories 0161/5009

IBU-SLO* ▼

Presentation Size 0, opaque pink capsule with a colourless transparent cap containing off-white almost spherical pellets. Each capsule contains 300 mg ibuprofen in a timed release formulation which provides a prolonged therapeutic effect.

Uses Non-steroidal anti-inflammatory agent with marked analgesic and antipyretic properties. For the treatment of rheumatoid arthritis; osteoarthritis; ankylosing spondylitis; seronegative (non-rheumatoid) arthropathies; acute periarticular disorders such as bursitis, capsulitis of the shoulder, tendinitis, tenosynovitis. For the relief of mild to moderate pain in sprains, strains, low back pain, dysmenorrhoea, dental and post-operative pain.

Dosage and administration *Adults and children over 12 years:* Dosage is variable according to the severity of the condition.

Recommended dose: Two capsules (600 mg) twice daily, taken night and morning. This may be increased to three capsules (900 mg) twice daily until the acute phase is controlled.

Recommended maintenance dose: One or two capsules twice daily.

Patients should be instructed not to chew or suck the capsules as this destroys the sustained release properties. Providing this is ensured the contents of a capsule may be sprinkled onto a spoonful of soft food, yoghurt or other similar substance for patients who experience difficulty in swallowing the capsules.

The evening dose of Ibu-Slo capsules will maintain a prolonged therapeutic effect throughout the night and help to prevent morning stiffness.

Contra-indications, warnings, etc Active peptic ulceration.

Precautions: As with other non-steroidal anti-inflammatory agents caution should be exercised when prescribing Ibu-Slo capsules during pregnancy and to nursing mothers. Traces of ibuprofen have been detected in breast milk but no adverse effects have been reported.

Ibu-Slo may be used, with caution, in patients with gastrointestinal disease and may often be tolerated by patients with peptic ulcer, or intolerance to other anti-rheumatic drugs.

Warnings and Adverse Effects: Generally well tolerated with a low incidence of side effects. Adverse effects may include gastrointestinal upsets, rashes, headache, nervousness, tinnitus and oedema. Gastrointestinal haemorrhage may rarely occur. Blurred vision, toxic amblyopia, thrombocytopenia and reversible oliguric renal failure have been reported during ibuprofen treatment, but were resolved on cessation of treatment.

Bronchospasm may be precipitated in patients suffering from, or with a previous history of, bronchial asthma or allergic disease.

If given to patients receiving anticoagulant therapy prothrombin time should be monitored at least daily for the first few days of combined treatment.

Overdosage – Signs and Symptoms: The following have been reported, headache, vomiting, drowsiness, loss of consciousness and hypotension.

Overdosage – Treatment: Symptomatic treatment is recommended directed at maintaining normal blood pressure, and correcting any electrolyte imbalance particularly potassium.

In children emesis and in adults gastric lavage may need to be considered, but only after careful assessment of the patients condition, in particular the level of consciousness.

Pharmaceutical precautions Keep container well closed. Store in a cool, dry place protected from light. Shelf life 3 years.

Legal category POM.

Package quantities Securitainers containing 120 capsules.

Further information Ibuprofen relieves pain, reduces joint inflammation and swelling and frequently facilitates restoration of mobility.

Product licence number 0161/0025.

KELOCYANOR*

Presentation 20 ml ampoule of a sterile aqueous rose-coloured solution containing the following active ingredient.

Dicobalt edetate 300 mg

Uses Specific antidote for acute cyanide poisoning.

Dosage and administration Treatment must be put into effect as soon as possible.

In the most severe cases of cyanide poisoning speed of administration is essential. It is however recommended that the intravenous injection is given steadily taking approximately one minute. If in the doctor's judgement the condition is less severe but still warrants the use of Kelocyanor it is recommended that the injection is administered slowly over a period of approximately five minutes. The intravenous injection of 1 × 20 ml ampoule of Kelocyanor should be followed immediately, using the same needle, by 1 × 50 ml ampoule of Dextrose Injection Strong BPC. If there is inadequate response a second ampoule of Kelocyanor may be given followed by a further 1 × 50 ml ampoule of Dextrose Injection Strong BPC. If there is still no response after five minutes a third ampoule may be given.

Contra-indications, warnings, etc The initial effect of Kelocyanor injection is a fall in blood pressure, a rise in pulse rate and sometimes retching. Immediately after

this phase lasting about one minute the patient should recover.

Cobalt is normally toxic and it is essential to ensure that the condition is cyanide poisoning. A few reports have been received of adverse reactions to Kelocyanor. These have generally occurred either in the absence of free cyanide ions (misdiagnosis) or when the degree of poisoning is very mild. The decision to use Kelocyanor is therefore a question of clinical judgement for the doctor and must be assessed on the severity of the symptoms at the time. Animal experiments have shown that there is a reciprocal antidote action between cyanide and cobalt and that the toxicity of cobalt is diminished by the administration of cyanide – demonstrated by a substantially increased LD₅₀ of Kelocyanor in the presence of cyanide.

Overdosage – Signs and Symptoms: These may be due to cobalt toxicity or to an anaphylactic type reaction, which may be dramatic. They include acute shock, drop in blood pressure, which may be considerable, cardiac irregularities, pain, collapse, urticaria, laryngeal and facial oedema and breathlessness.

Overdosage – Treatment: Intensive supportive therapy is required directed at maintaining blood pressure, a clear airway, respiration and circulation and correcting fluid loss. Patients should be carefully monitored for at least 48 hours.

This information is based only on those cases of misdiagnosis (that is administration in the absence of free cyanide ions or the presence of only low levels) reported to us, and this therapy resulted in complete recovery.

Pharmaceutical precautions Store in a cool place. Shelf-life 3 years.

Legal category POM.

Package quantities Carton containing 6 × 20 ml ampoules.

Further information Nil.

Product licence number 0161/5011.

MADECASSOL*

Presentation Ointment: White ointment containing 1% titrated extract of *Centella asiatica*.

Powder: White powder containing 2% titrated extract of *Centella asiatica*.

Uses Topical use for minor wounds, e.g. bedsores, urinary rash, burns, chapped hands, sunburn, etc.

Dosage and administration Madecassol Ointment and Powder should be applied to the lesion as often as required, preferably two or three times daily. In addition to the usual aseptic precautions, the wound should be cleaned before each application.

Contra-indications, warnings, etc Normal wound hygiene should accompany the use of Madecassol. It does not possess antibiotic properties. Not suitable for ophthalmic use.

Side effects: Very rarely symptoms such as pruritus, burning sensation and eczematous rash have occurred.

Overdosage – Signs and Symptoms: The ingestion of sufficient Madecassol ointment or powder to produce untoward symptoms is considered unlikely, although we have no experience of this occurring.

Overdosage Treatment: No specific treatment is recommended.

Pharmaceutical precautions No special storage requirements.

Legal category GSL.

Package quantities *Ointment:* Tube containing 10 g Madecassol Ointment 1%.

Powder: Puffer pack containing 2 g Madecassol Powder 1%.

Further information Ointment base does not contain anolin.

Product licence numbers

Ointment 0161/5012

Powder 0161/5013

NYDRANE*

Presentation White, uncoated tablets engraved 'Nydrane' on one side and a break line on the reverse, containing the following active ingredient:

3eclamide 500 mg

Uses Behaviour disorders, in epileptic or non-epileptic patients, particularly where instability is marked and aggressiveness a feature. Grand mal and psychomotor epilepsy.

Dosage and administration

1. Behaviour disorders

Adults: Initially 6 tablets (sometimes up to 8 tablets) of Nydrane daily in divided doses. Maintenance dosage will vary according to patient response. This will usually be from 3 to 6 tablets of Nydrane daily, but occasionally more may be required.

Children 5–10: 3 tablets daily in divided doses.

Children under 5: 1½–2 tablets daily in divided doses.

2. Epilepsy

Caution – do not attempt immediate replacement of existing therapy.

Adults: Initially 6 tablets (sometimes up to 8 tablets) of Nydrane daily in divided doses. It is essential to delay reducing previous therapy until the maximum therapeutic effect of Nydrane has been obtained, which may take up to four weeks. Then existing medication may be reduced slowly and cautiously while maintaining control.

Children 5–10: 3 tablets daily in divided doses.

Children under 5: 1½–2 tablets daily in divided doses.

Contra-indications, warnings, etc

Precautions: In epileptics it is essential to delay reducing previous therapy until the maximum therapeutic effect of Nydrane has been obtained, which may take up to four weeks. Caution is particularly essential in patients with a tendency to develop status epilepticus, or with a history of previous attacks. Although no teratogenic effects have been reported during many years of use, in common with the majority of drugs the use of Nydrane during pregnancy should be avoided if possible. Secretion into breast milk; no information is available.

Side effects: The very few side effects reported have been of a mild and transient nature and include eucopenia, renal disturbance, loss of weight, dizziness, gastro-intestinal symptoms, skin irritation and rash.

Overdosage – Signs and Symptoms: Vertigo and vomit-

ing are thought most likely to occur. Nystagmus has been reported. Theoretically there is a possibility of increased drowsiness leading to coma.

Overdosage – Treatment: Symptomatic treatment is recommended and neurological and biochemical monitoring for at least 48 hours. Patients have recovered from overdoses without special treatment. This information is based on two reported cases only.

Pharmaceutical precautions No special storage requirements.

Legal category POM.

Package quantities Securainers containing 100 or 500 tablets.

Further information Free from side-effects commonly associated with anticonvulsant drugs, including gum hypertrophy and somnolence. Specific action in behaviour disorders, particularly if instability is marked and aggressiveness a feature.

Product licence number 0161/5015.

RONYL*

Presentation White, uncoated tablets with 'Ronyl' engraved on one side and a break line on the reverse, containing the following active ingredient:

Pemoline 20 mg

Uses Psychogenic fatigue and fatigue arising post-operatively, or during convalescence. In geriatrics to avoid 'cat napping'. To combat somnolence in combination with tranquillising drugs, and antihistamines.

Dosage and administration In order to avoid interference with sleep, Ronyl should preferably be given before 2 p.m.

Adults: 1 tablet twice daily (the dosage should be adjusted according to individual response and body weight; normally a maximum of 4 tablets daily is sufficient; however, in special situations up to 6 may be given).

Children over 6 years and elderly patients: ½ tablet twice daily. (The dosage should be adjusted according to individual response and body weight and up to 2 tablets daily can be given).

Contra-indications, warnings, etc

Precautions: Theoretically a combination of Ronyl and a monoamine oxidase inhibitor could result in enhanced CNS stimulation, and this should be considered before administering Ronyl with this group of drugs. Although no teratogenic effects have been reported during many years of use, in common with the majority of drugs the use of Ronyl during pregnancy should be avoided if possible. No determinations of pemoline in breast milk have been carried out due to technical difficulties. If it is considered absolutely essential to administer Ronyl to nursing mothers the infant should be carefully monitored.

Side effects: These are mild and transient. Dizziness, sweating, palpitations and headache have been reported only rarely.

Overdosage – Signs and Symptoms: Headache, palpitations, tachycardia, extreme restlessness, dizziness and sweating. In some cases vomiting and constant choreiform movements.

Overdosage – Treatment: This is essentially the same as for any drug which has a stimulant effect on the central nervous system. Intensive supportive therapy is generally recommended.

Gastric lavage may be required but should only be considered after careful assessment of the patients condition and the time since ingestion which should be no more than four hours.

In two reported cases phenobarbitone and I/V Dextrose 5% were successfully used, a more recent report suggests diazepam may be of value in controlling the hyperactivity. Neurological and biochemical monitoring is recommended for two to three days.

Pharmaceutical precautions No special storage requirements.

Legal category POM.

Package quantities Securitainers containing 50 or 250 tablets.

Further information No reports of addiction. Removed from control under Misuse of Drugs Act 1971.

Product licence number 0161/5017.

SLO-PHYLLIN*

Presentation Capsules containing Theophylline BP (anhydrous) in a timed release formulation which provides a prolonged therapeutic effect over 12 hours.

60 mg: Size 2 opaque white capsule with a clear colourless cap, filled with white pellets. Each capsule contains 60 mg Theophylline BP (anhydrous).

125 mg: Size 1 opaque dark brown capsule with a clear colourless cap, filled with a mixture of brown and white pellets. Each capsule contains 125 mg Theophylline BP (anhydrous).

250 mg: Size 0 opaque blue capsule with a clear colourless cap, filled with a mixture of blue and white pellets. Each capsule contains 250 mg Theophylline BP (anhydrous).

Uses As a bronchodilator in the symptomatic and prophylactic treatment of the asthmatic and for reversible bronchoconstriction associated with chronic bronchitis, bronchial asthma and emphysema.

Dosage and administration *Adults and children over 12 years:* 250–500 mg twice daily.

Children 6–12 years (20–35 kg): 125–250 mg twice daily.

Children 2–6 years (10–20 kg): 60–120 mg twice daily. Initially the lowest dosage suggested for each age group is recommended.

This may be increased gradually if optimal bronchodilator effects are not achieved. Generally the total daily (24 hour) dosage should not exceed 20 mg/kg body weight (ranging from 13 mg/kg body weight for adults to 24 mg/kg body weight for children under 9 years), given in divided doses at intervals of 12 hours. If a higher dosage is required it is strongly recommended that plasma theophylline concentrations should be monitored, since it has been established that significant variations occur among individuals in the rate of drug elimination.

N.B.: Careful monitoring is recommended for patients with congestive heart failure or hepatic dysfunction as

they may have lower total clearance of theophylline which could lead to higher than normal plasma levels.

Patients should be instructed not to chew or suck capsules as this destroys the sustained release properties. Providing that this is ensured the contents of a capsule may be sprinkled onto a spoonful of soft food such as yoghurt or other suitable substance for children who experience difficulty in swallowing.

Contra-indications, warnings, etc

Precautions: Normal for theophylline – safety in human pregnancy has not been established, and theophylline can cross the maternal placenta. Caution should be exercised in patients with peptic ulcers, cardiovascular disease (especially if cardiac arrhythmias are present) or in severe hypertension.

Slo-phyllin should not be used concurrently with other preparations containing xanthine derivatives. It is recommended that nursing mothers take their dose of theophylline after breast feeding, since theophylline is distributed to breast milk.

Caution is particularly advised if it is necessary to administer aminophylline to patients receiving a slow release theophylline preparation. Monitoring of plasma theophylline concentrations is recommended at the earliest opportunity.

Side-effects: Tend to occur only if theophylline blood levels exceed 20 mcg/ml and a reduction of daily dosage usually corrects this problem. Gastric irritation, nausea, vomiting and abdominal discomfort should be anticipated in 10% of patients started on a dose of 16 mg/kg body weight daily. Other side-effects are: palpitation, fall in blood pressure, headache, occasional diarrhoea and insomnia. CNS stimulation and diuresis especially in children.

Whilst children may sometimes require higher than conventional doses, the above side-effects may not always be either apparent or expressed and it is, therefore, important not to exceed the recommended dose unless plasma theophylline concentrations are monitored.

Overdosage – Signs and Symptoms: These are varied both in degree and in order of appearance. They include nausea, vomiting, haematemesis, diuresis, restlessness, irritability possibly leading to tremors, convulsions, drowsiness and coma. It is important to be aware that with xanthine derivatives even small doses may produce serious complications and the first symptom could be a convulsion. There may be a latent period of up to 10 hours before any symptoms appear.

Overdosage – Treatment: Intensive therapy is required most importantly directed at maintaining respiration, circulation and correcting fluid loss and electrolyte imbalance, especially potassium. Gastric lavage should only be considered after careful assessment of the patient's condition in particular the level of consciousness.

Under these circumstances, oral activated charcoal may provide a useful alternative treatment. Recent experience gained from overdosage with other theophylline containing preparations would suggest that treatments directed at increasing drug elimination such as charcoal haemoperfusion are more effective. It is essential to monitor the patient carefully for two or three days.

Drug interactions: Relatively few have been documented; these have involved phenytoin, cimetidine, diazepam, lithium carbonate, propranolol, frusemide,

Blood dyscrasias (agranulocytosis, thrombocytopenia, aplastic anaemia) may occur suddenly after a small dose or insidiously after prolonged therapy, particularly in the elderly. Blood counts should be monitored regularly both before and during therapy. Therapy should be stopped if symptoms suggestive of these complications arise (e.g. bruising, fever, sore throat and rash).

Isolated occurrences of an 'acute pulmonary syndrome' – marked by dyspnoea, fever, shadows in radiographs of the lungs, and sometimes also by eosinophilia – have been reported. Although a causal relationship has not been proven, the drug should be withdrawn at first signs of this potentially serious syndrome, for the treatment of which corticosteroids and supportive cardiotherapy may be necessary.

Adverse effects of phenylbutazone therapy should always be weighed against the severity of the patient's condition and the expected clinical effect.

Accidental overdose: There is no known antidote to Butazolidin Alka and treatment is symptomatic. Immediate treatment consists of forced emesis to recover undigested tablets. This is followed by gastric lavage with sodium bicarbonate solution.

Pharmaceutical precautions *Storage:* Tablets – protect from heat and moisture.

Legal category POM.

Package quantities *Mantle tablets:* Containers of 100 and 250.

Further information When rheumatic patients require supplementary antacids the unique formulation of Butazolidin Alka, a mantle of antacids around a central core of Butazolidin and antacid, allows a high percentage of these patients to continue to receive long-term antirheumatic therapy without distressing gastric upsets or the uncertainties of multiple medications with a consequent increased opportunity for uninterrupted successful long-term antirheumatic therapy.

Product licence number 0001/5003.

EURAX*

Presentation The active ingredient, Crothamiton BP, is presented as: white to cream coloured, non-staining ointment with an odour of perfume, containing 10% crothamiton. Also as a white to yellowish-white non-staining emulsion, with an odour of perfume, containing 10% crothamiton.

Uses *Antipruritic/sarcopticide:* Neurodermatitis; anogenital, senile pruritus. Pruritus associated with dermatoses. Pruritus as a symptom of systemic disease; allergic pruritus in the presence of diabetes mellitus or jaundice; pruritus due to drug hypersensitivity. Scabies.

Dosage and administration Eurax is applied externally in either ointment or lotion form.

Method of use: *Pruritus:* Eurax Ointment or Lotion should be massaged into the affected areas as frequently as required to prevent itching. Treatment can be expected to remain effective for 6 to 10 hours after each application.

Scabies: The patient should take a hot bath, using soap and flannel, and dry himself on a towel. Eurax should then be applied to the body from the chin down, with particular attention to the interdigital spaces, the flexor surfaces of the wrists, the inner and outer aspects of the

elbows, the axillae, the under surface of the breasts, the umbilicus, the buttocks, and the inner aspects of the thighs. To ensure complete eradication, a second application 24 hours later is advisable, but a bath should not be taken until the day after, to wash off the application. The clothes should then be changed and sheets sent to the laundry.

Contra-indications, warnings, etc

Contra-indications: Acute exudative dermatoses.

Eurax should not be used near the eyes since contact with the eyelids may give rise to conjunctival inflammation.

Pharmaceutical precautions *Storage:* Ointment and Lotion – protect from heat.

Dilutions: Diluents or other additives to these formulations are not recommended.

Legal category P.

Package quantities

Ointment: Tubes of 30 g and 100 g.

Lotion: Bottles of 150 ml and 1 litre.

Further information Nil.

Ointment 0001/5008

Lotion 0001/5009

EURAX* – HYDROCORTISONE

Presentation The active ingredients, Crothamiton BP and Hydrocortisone BP, are presented as: white to cream coloured soft cream with a faint odour of perfume, containing Crothamiton BP 10% and Hydrocortisone BP 0.25%.

Uses *Antipruritic/anti-inflammatory:* Eurax-Hydrocortisone is useful in the symptomatic treatment of many types of itching dermatoses, since it combines a distinctive antipruritic action with bacteriostatic, anti-inflammatory and anti-allergic properties.

Pruritus ani, pruritus vulvae, pruritus scroti, senile pruritus.

Dermatoses with associated pruritus.

Seborrhoeic dermatitis, eczema, contact dermatitis, lichen simplex, dermatitis herpetiformis, neurodermatitis, pityriasis rosea, varicose eczema, urticaria.

Allergic pruritus; pruritus in the presence of diabetes mellitus or jaundice; pruritus due to drug hypersensitivity.

Dosage and administration Eurax-Hydrocortisone is applied externally.

Method of application: A thin layer of Eurax-Hydrocortisone Cream should be applied to the affected area two to three times a day.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to crothamiton.

Chickenpox, skin eruptions following vaccination, tuberculosis of the skin, and syphilitic skin affections.

Eurax-Hydrocortisone should not be used in the presence of acute exudative dermatoses.

Precautions: It has been shown that corticosteroids can be absorbed by eczematous skin. Long-term administration of Eurax-Hydrocortisone to large areas should, therefore, be avoided if possible, regardless of whether occlusion is used. If such administration is unavoidable, precautions similar to those taken with patients receiving

danger of cardiac decompensation. Butazolidin is also contra-indicated in the presence of renal and hepatic disease, including recent hepatitis. History of gastro-intestinal ulceration, blood dyscrasia, drug rash or known sensitivity to pyrazoles (and also lignocaine in the case of Butazolidin ampoules).

Precautions: History of dyspepsia.

Since Butazolidin may potentiate the action of coumarin-type anticoagulants by displacement from plasma protein binding, frequent estimations of prothrombin levels should be undertaken when these drugs are administered concurrently. Similarly, Butazolidin potentiates certain oral hypoglycaemic agents and sulphonamides, the dosage of which may need reducing.

It is suggested that Butazolidin be used with caution in pregnant women, weighing the potential risks against the possible benefits.

Side-effects: Gastro-intestinal intolerance or bleeding due to Butazolidin may occur.

Drug rash, oedema, haematemesis, salivary gland swelling, goitre and jaundice due to intrahepatic cholestasis or parenchymal hepatitis have also been reported.

Blood dyscrasias (agranulocytosis, thrombocytopenia, aplastic anaemia) may occur suddenly after a small dose or insidiously after prolonged therapy, particularly in the elderly. Blood counts should be monitored regularly both before and during therapy. Therapy should be stopped if symptoms suggestive of these complications arise (e.g. bruising, fever, sore throat and rash).

Isolated occurrences of an 'acute pulmonary syndrome' – marked by dyspnoea, fever, shadows in radiographs of the lungs, and sometimes also by eosinophilia – have been reported. Although a causal relationship has not been proven, the drug should be withdrawn at first signs of this potentially serious syndrome, for the treatment of which corticosteroids and supportive cardiotherapy may be necessary.

Adverse effects of phenylbutazone therapy should always be weighed against the severity of the patient's condition and the expected clinical effect.

Accidental overdosage: There is no known antidote to Butazolidin and treatment is symptomatic. Immediate treatment consists of forced emesis to recover undigested tablets. This is followed by gastric lavage.

Pharmaceutical precautions *Storage:* Tablets 100 mg and 200 mg – protect from moisture. Suppositories 250 mg – protect from heat. Ampoules 600 mg in 3 ml with 1% Xylocaine – store in a cold place (2–7°C).

Legal category POM.

Package quantities *Tablets 100 mg:* Containers of 100 and 1,000.

Tablets 200 mg: Containers of 100 and 500.

Suppositories 250 mg: Boxes of 50.

Ampoules 600 mg in 3 ml with 1% Xylocaine: Boxes of 5.

Further information The therapeutic effectiveness of Butazolidin, a non-hormonal antirheumatic agent is based on its powerful and prolonged analgesic activity together with valuable anti-inflammatory and antipyretic activity. This threefold action provides prompt and sustained relief from pain with improvement in functional capacity in a wide range of rheumatic and allied rheumatic conditions.

BUTAZOLIDIN* ALKA

Presentation The active ingredients, Phenylbutazone BP 100 mg, Dried Aluminium Hydroxide Gel BP 100 mg, and Magnesium Trisilicate BP 150 mg, are presented as: round, bi-convex, white, compression-coated tablets, approximately 11.7 mm diameter, impressed GEIGY on one side.

Uses Rheumatoid arthritis, osteoarthritis, ankylosing spondylitis and acute gout.

Osteoarthritis of the spine and degenerative disc disease presenting as lumbago, sciatica or radiculitis.

Prolapsed intervertebral disc.

Reiter's disease and other seronegative (non-rheumatoid) arthropathies.

Bone pain associated with Paget's disease and secondary neoplasm.

Moderate to extensive superficial thrombophlebitis.

Dosage and administration Butazolidin Alka is given orally in tablet form.

Adult: For the initial 48 hours 400–600 mg daily in divided doses with meals. Maintenance doses should be reduced to the minimum amount that will provide continuous therapeutic control, usually 200–300 mg daily.

Note: In acute gout a maximum dosage of 800 mg daily may be necessary.

Paediatric: Dosage is in the range 5–10 mg per kg, with emphasis on the lower end of the scale. As a guide the small seven year old and younger children should be given 1 × 100 mg tablet per day. In children of average weight between 7–12 years of age, 2 × 100 mg tablets per day in divided doses is sufficient.

Contra-indications, warnings, etc

Contra-indications: Butazolidin Alka is contra-indicated in the presence of oedema or hypertension where there is danger of cardiac decompensation. Butazolidin Alka is also contra-indicated in the presence of renal and hepatic disease, including recent hepatitis, history of gastro-intestinal ulceration, blood dyscrasia, drug rash or known sensitivity to pyrazoles.

Precautions: History of dyspepsia.

Since Butazolidin Alka may potentiate the action of coumarin-type anticoagulants by displacement from plasma protein binding, frequent estimations of prothrombin levels should be undertaken when these drugs are administered concurrently. Similarly, Butazolidin Alka potentiates certain oral hypoglycaemic agents and sulphonamides, the dosage of which may need reducing.

It is suggested that Butazolidin Alka be used with caution in pregnant women, weighing the potential risks against the possible benefits.

Side-effects: Whilst the incidence of gastro-intestinal intolerance or bleeding is significantly reduced with Butazolidin Alka, other side-effects associated with Butazolidin should be anticipated.

Drug rashes, oedema, haematemesis, salivary gland swelling, goitre and jaundice due to intrahepatic cholestasis or parenchymal hepatitis have been reported.

It is suggested that Butacote be used with caution in pregnant women, weighing the potential risks against the possible benefits.

Side-effects: Whilst gastro-intestinal intolerance or bleeding due to Butacote is rarely encountered, the following side-effects generally associated with Butazolidin should be anticipated: drug rash, oedema, haematemesis, salivary gland swelling, goitre and jaundice due to intrahepatic cholestasis or parenchymal hepatitis have also been reported.

Blood dyscrasias (agranulocytosis, thrombocytopenia, aplastic anaemia) may occur suddenly after a small dose or insidiously after prolonged therapy, particularly in the elderly. Blood counts should be monitored regularly both before and during therapy. Therapy should be stopped if symptoms suggestive of these complications arise (e.g. bruising, fever, sore throat and rash).

Isolated occurrences of an 'acute pulmonary syndrome' – marked by dyspnoea, fever, shadows in radiographs of the lungs, and sometimes also by eosinophilia – have been reported. Although a causal relationship has not been proven, the drug should be withdrawn at first signs of this potentially serious syndrome, for the treatment of which corticosteroids and supportive cardiotherapy may be necessary.

Adverse effects of phenylbutazone therapy should always be weighed against the severity of the patient's condition and the expected clinical effect.

Accidental overdosage: There is no known antidote to Butacote and treatment is symptomatic. Immediate treatment consists of forced emesis to recover undigested tablets. This is followed by gastric lavage.

Pharmaceutical precautions *Storage:* Tablets – protect from heat and moisture.

Legal category POM.

Package quantities *Tablets 100 mg:* Containers of 100 and 500.

Tablets 200 mg: Containers of 100.

Further information Pharmacological studies confirm that the special formulation of Butacote is completely reliable and will not crack or disintegrate in the acid pH of the gastric juice, but rapidly disintegrates and dissolves in the alkaline pH of the small bowel. Clinical studies confirm that this mode of action significantly reduces the incidence of gastric upsets generally experienced with potent antirheumatics and that it is an effective therapy in the treatment of a wide range of rheumatic conditions.

Tablets 200 mg 0001/0056

BUTAZOLIDIN*

Presentation The active ingredient, Phenylbutazone BP, is presented as: red, sugar-coated tablets, bi-convex, approximately 7.6 mm diameter and imprinted GEIGY on one side, each containing 100 mg.

White, sugar-coated tablets, bi-convex, approximately 10 mm diameter and imprinted GEIGY on one side, each containing 200 mg.

White, waxy suppositories each containing 250 mg.

Ampoules of clear glass containing 600 mg Butazolidin Sodium in 3 ml with 1% Xylocaine.t

Uses Rheumatoid arthritis, osteoarthritis, ankylosing spondylitis and acute gout.

Osteoarthritis of the spine and degenerative disc disease presenting as lumbago, sciatica or radiculitis.

Prolapsed intervertebral disc.

Reiter's disease and other seronegative (non-rheumatoid) arthropathies.

Bone pain associated with Paget's disease and secondary neoplasm.

Moderate to extensive superficial thrombophlebitis.

Dosage and administration Butazolidin may be administered orally, rectally or by deep intramuscular injections, all routes being suitable for the full range of indications.

Oral dosage (adult): For the initial 48 hours 400–600 mg daily in divided doses with meals. Patients with sensitive stomachs should be given a sodium-free antacid at the same time. Maintenance doses should be reduced to the minimum amount that will provide continuous therapeutic control, usually 200–300 mg daily.

Note: In acute gout a maximum dosage of 800 mg daily may be necessary.

Rectal dosage: Suppositories of Butazolidin (250 mg) have been found to be a therapeutically effective alternative or supplementary dosage form.

One or two Butazolidin suppositories (250–500 mg) daily, as a sole therapy achieves a clinical response similar to that obtained by oral maintenance therapy.

When a suppository is required on retiring to control night pain, the total daily dosage of tablets and suppositories should not exceed 650 mg initially, with subsequent reduction to the maximum combined maintenance dose (350 mg).

Parenteral dosage: 1 × 3 ml ampoule (600 mg Butazolidin sodium) every two or three days. Injections can be given less frequently as the patient improves.

Injections should be given into the gluteal muscles only (and never into the arm), under aseptic conditions. The injection should be made into the upper quadrant of the gluteal region (*m. gluteus medius*) with the needle directed sagittally and perpendicularly to the frontal plane. The needle should not be directed medially or caudally, because of the danger of striking the sciatic nerve. From the upper outer quadrant the general direction of the needle should be towards the iliac crest. The injection must be definitely intramuscular, i.e. deep enough to avoid deposition of the drug in fatty tissue. The injection should be made very slowly, with repeated aspiration, and not against abnormal resistance. If the patient feels pain or great discomfort, either at the site of injection or down the leg, the injection should be stopped at once. Abscess formation has occasionally been reported and severe peripheral nerve damage has been observed following a misplaced injection. These complications should not occur if the above precautions are observed.

The intravenous route is **not** advised.

Oral dosage (paediatric): Dosage is in the range 5–10 mg per kg, with emphasis on the lower end of the scale. As a guide the small seven year old and younger children should be given 1 × 100 mg tablet per day; in children of average weight between 7–12 years of age, 2 × 100 mg tablets per day in divided doses is sufficient.

Contra-indications, warnings, etc

Contra-indications: Butazolidin is contra-indicated in the presence of oedema or hypertension where there is

† Licensed by AB Astra (Sweden).

Indication Prevention of cardiac mortality following recent myocardial infarction.

Dosage and administration

Administration: Anturan is administered orally in tablet form with meals or milk.

Dosage: *Adults:* one 200 mg tablet four times daily, commencing approximately one month after myocardial infarction.

Children: Paediatric usage not established.

Contra-indications, warnings, etc

Contra-indications: Active peptic ulcer. Sensitivity to phenylbutazone or other pyrazole derivatives. Severe hepatic disease.

Precautions: Use with caution in patients with impaired renal function or nephrolithiasis; in these cases, regular assessment of renal function is indicated.

Use with caution in patients with healed peptic ulcer.

Salicylates increase bleeding time and may cause haemorrhage; caution should be exercised when administering Anturan and aspirin together.

Since Anturan may potentiate the action of coumarin-type anticoagulants, frequent estimation of prothrombin time should be undertaken when these drugs are given concurrently, and the dosage of the anticoagulant adjusted accordingly.

Anturan may also potentiate the action of other plasma protein-binding drugs such as hypoglycaemic agents and sulphonamides, which may necessitate a modification in dosage.

Anturan should be used with caution in pregnant women, weighing the potential risks against the possible benefits.

Warnings and side-effects: During the early stages of treatment in patients with hyperuricaemia or gout, acute attacks of gout may be precipitated.

To help prevent episodes of urolithiasis or renal colic, ensure adequate fluid intake and alkalisation of the urine during initial stages of therapy.

Gastro-intestinal bleeding has been reported; transient gastro-intestinal side-effects may occur and are usually of a mild nature.

Rash or blood dyscrasias may occur, and are contra-indications to further treatment; onset may be sudden or gradual, and occur after small doses or after long periods of treatment.

For the early detection of a haematological abnormality, careful clinical supervision and a full blood count should be done before and at regular intervals during treatment.

Invalidation of results of renal function tests involving p-aminohippuric acid (PAH), phenolsulphthalein (PSP), or other organic acids may occur.

Accidental overdosage There is no antidote to Anturan and treatment is symptomatic. Immediate treatment consists of forced emesis to recover undigested tablets. This is followed by gastric lavage, preferably with mild alkaline solutions such as sodium bicarbonate solution, and supportive therapy as indicated.

Pharmaceutical precautions *Storage:* Protect from heat and moisture.

Legal category POM.

Package quantities Cartons of 112 consisting of 4 calendar reminder foils of 28.

Further information Upon exposure to a thrombo-

genic stimulus such as damaged vasculature, platelets adhere to the exposed sub-endothelium and release mediators which cause further platelet adhesion, and thrombus formation. This thrombus, or its embolisation distally, may cause vessel occlusion; emboli released into the coronary microcirculation may lead to fatal arrhythmia. As a modulator of platelet function Anturan inhibits thrombus formation, and reduces the risk of sudden cardiac death. It has also been shown to protect the vascular endothelium in primates.

Product licence number 0001/0080.

BUTACOTE*

Presentation The active ingredient, Phenylbutazone BP, is presented as sugar-coated, enteric tablets, bi-convex, approximately 7.6 mm diameter, pale-violet coloured and imprinted GEIGY on one side, each tablet containing 100 mg.

Butacote is also available as sugar-coated, enteric tablets bi-convex, approximately 10.7 mm in diameter, pale-violet coloured and imprinted GEIGY on one side, each tablet containing 200 mg.

Uses Rheumatoid arthritis, osteoarthritis, ankylosing spondylitis and acute gout.

Osteoarthritis of the spine and degenerative disc disease presenting as lumbago, sciatica or radiculitis.

Prolapsed intervertebral disc.

Reiter's disease and other seronegative (non-rheumatoid) arthropathies.

Bone pain associated with Paget's disease and secondary neoplasms.

Moderate to extensive superficial thrombophlebitis.

Dosage and administration Butacote is given orally in tablet form.

Adults: For the initial 48 hours 400–600 mg daily in divided doses with meals.

Maintenance doses should be reduced to the minimum amount that will provide continuous therapeutic control, usually 200–300 mg daily.

Note: In acute gout a maximum dosage of 800 mg daily may be necessary.

Paediatric: Dosage in the range 5–10 mg per kg, with emphasis on the lower end of the scale. As a guide the small seven-year-old and younger children should be given 1 × 100 mg tablet per day.

In children of average weight between 7–12 years of age, 2 × 100 mg tablets per day in divided doses is sufficient.

Contra-indications, warnings, etc

Contra-indications: Butacote is contra-indicated in the presence of oedema or hypertension where there is danger of cardiac decompensation. Butacote is also contra-indicated in the presence of: renal and hepatic disease, including recent hepatitis, history of gastro-intestinal ulceration, blood dyscrasia, drug rash or known sensitivity to pyrazoles.

Precautions: History of dyspepsia.

Since Butacote may potentiate the action of coumarin-type anticoagulants by displacement from plasma protein binding, frequent estimations of prothrombin levels should be undertaken when these drugs are administered concurrently. Similarly, Butacote potentiates certain oral hypoglycaemic agents and sulphonamides, the dosage of which may need reducing.

Andursil during the first three months of pregnancy is only advised if there are compelling reasons for so doing.

Side-effects: Side-effects are unlikely to occur in the recommended dosage.

Pharmaceutical precautions *Storage:* Protect from heat.

Legal category P.

Package quantities *Suspension:* Bottles of 100 ml and 300 ml.

Tablets: Carton of 100 tablets containing 5 packs of 20 tablets.

Further information *In vitro* tests on Andursil Suspension and Tablets have shown that the optimum buffering pH of between pH 3.0 and pH 5.0 is reached very quickly and is prolonged without producing a systemic alkalosis. Andursil is non-constipating and is not a laxative.

Product licence numbers

Andursil Tablets 0001/0060

ANTURAN*

Presentation The active ingredient, Sulphinpyrazone BP is presented as pale yellow, sugar-coated tablets, bi-convex, approximately 8.5 mm diameter imprinted GEIGY on one side, containing 100 mg in each tablet.

Uses *Mode of action:* Anturan lowers serum urate levels by blocking tubular re-absorption, thereby increasing renal excretion of uric acid. As a result of increased excretion, serum urate deposits are mobilised and tophi are no longer formed.

Indications: Chronic including tophaceous gout, recurrent gouty arthritis. Hyperuricaemia.

Dosage and administration *Administration:* Anturan is administered orally in tablet form, with meals or milk.

Dosage: Adults: Chronic gout, hyperuricaemia: Anturan should be given daily in equally divided doses; in some cases a single dose may suffice. 100–200 mg daily increasing gradually (over the first two or three weeks) to 600 mg (rarely 800 mg) daily and maintained until serum urate level has fallen within the normal range. Subsequent dosage should be reduced to the lowest level which maintains serum urate within the normal range. Maintenance dose may be as low as 200 mg daily, and rarely 100 mg.

Chronic gout with renal impairment: Anturan is effective in all but the most severely affected patients. Low dosage should be used initially and increased only under detailed supervision until the correct maintenance dose is established.

Children: Paediatric usage not established.

Contra-indications, warnings, etc

Contra-indications: Active peptic ulcer. Sensitivity to phenylbutazone or other pyrazole derivatives. Severe hepatic disease.

In the treatment of chronic gout salicylates antagonise the action of Anturan and should not be given concurrently.

Precautions: Use with caution in patients with impaired renal function or nephrolithiasis; in these cases, regular assessment of renal function is indicated.

Use with caution in patients with healed peptic ulcer.

Since Anturan may potentiate the action of coumarin-type anticoagulants, frequent estimation of prothrombin time should be undertaken when these drugs are given concurrently, and the dosage of the anticoagulant adjusted accordingly.

Anturan may potentiate the action of plasma protein-binding drugs such as hypoglycaemic agents and sulphonamides, which may necessitate a modification in dosage.

Anturan should be used with caution in pregnant women, weighing the potential risks against the possible benefits.

Side-effects: During the early stages of the treatment in patients with hyperuricaemia or gout, acute attacks of gout may be precipitated.

To help prevent episodes of urolithiasis or renal colic, ensure adequate fluid intake and alkalinisation of the urine during initial stages of therapy.

Gastro-intestinal bleeding has been reported; transient gastro-intestinal side-effects may occur and are usually of a mild nature.

Rash or blood dyscrasias may occur, and are contra-indications to further treatment; onset may be sudden or gradual, and occur after small doses or after long periods of treatment.

For the early detection of a haematological abnormality, careful clinical supervision and a full blood count should be done before and at regular intervals during treatment.

Invalidation of results of renal function tests involving p-aminohippuric acid (PAH), phenolsulphthalein (PSP) or other organic acids may occur.

Accidental overdose: There is no antidote to Anturan, and treatment is symptomatic. Immediate treatment consists of forced emesis to recover undigested tablets. This is followed by gastric lavage preferably with mild alkaline solution such as sodium bicarbonate solution and supportive therapy as indicated.

Pharmaceutical precautions *Storage:* Tablets – protect from moisture.

Legal category POM.

Package quantities *Tablets 100 mg:* Containers of 100.

Further information Anturan lowers serum uric acid levels by blocking tubular re-absorption of uric acid and increasing renal excretion where glomerular filtration is still adequate and where tubular function is not too severely impaired.

Product licence number 0001/5002.

ANTURAN* 200 MG TABLETS

Presentation Tablets containing 200 mg Sulphinpyrazone BP, light yellow, sugar-coated, round, biconvex approximately 10.6 mm diameter printed GEIGY on one side.

Mode of action Regulation of platelet function.

Anturan has been shown to increase platelet survival time and decrease platelet turnover in thromboembolic conditions. In addition to inhibiting platelet adhesion and aggregation, Anturan has also been shown to inhibit the platelet release reaction and prostaglandin synthesis, processes known to be important in thromboembolism.

pregnancy; there is evidence of harmful effects in pregnancy in animals, when given in exceptionally high doses.

Nursing mothers should be advised to cease breast feeding.

Drug interactions: Anafranil should not be given concurrently, or within 2 weeks of cessation of therapy, with monoamine oxidase inhibitors.

Anafranil may decrease the antihypertensive effect of guanethidine, debrisoquine, bethanidine and possibly clonidine, and methyl dopa. It would be advisable to review all antihypertensive therapy during treatment with tricyclic antidepressants.

Anafranil should not be given with sympathomimetic agents such as adrenaline, ephedrine, isoprenaline, noradrenaline, phenylephrine and phenylpropanolamine.

Barbiturates may decrease and methylphenidate and neuroleptics may increase the plasma level of clomipramine.

Side-effects: The following adverse effects, although not necessarily all reported with Anafranil have occurred with other tri/tetracyclic antidepressants:

Atropine-like side effects including dry mouth, disturbances of accommodation, tachycardia, constipation and hesitancy of micturition may occur early in treatment, but usually lessen.

Other possible adverse effects include nausea, drowsiness, sweating, postural hypotension, hypomania, tremor, paraesthesia, ataxia and, rarely, skin rashes.

Male patients may occasionally experience ejaculation disorders and, more rarely, impotence. Women occasionally experience orgasmic impotence.

Epileptiform convulsions have been experienced in a small number of patients.

Serious adverse effects are rare; these include impaired liver function and jaundice, bone marrow depression, including leucopenia, eosinophilia and thrombocytopenia. Agranulocytosis has occasionally occurred in patients receiving tricyclic antidepressants. It is advisable to perform blood counts during treatment with Anafranil especially if the patient develops fever, sore throat or other signs of infection. Cardiac arrhythmias and severe hypotension are likely to occur with high dosage or in deliberate overdose. They may also occur in patients with pre-existing heart disease taking normal dosage.

Although not indicative of addiction, withdrawal symptoms may occur on abrupt cessation of therapy and include insomnia, irritability and excessive perspiration.

Withdrawal symptoms in neonates whose mothers receive tri/tetracyclic antidepressants during the third trimester have also been reported.

Psychotic manifestations, including mania and paranoid delusions, may be exacerbated during treatment with tricyclic antidepressants.

Accidental overdose: Major symptoms of overdose include coma, convulsions, cardiovascular disturbances. Gastric lavage should be performed immediately and patients removed to an intensive care unit where cardiac monitoring is possible. Although there is no specific antidote, slow intravenous injection of physostigmine has yielded particularly good results in the presence of central nervous disturbances (coma, myoclonia, athetoid movements); physostigmine may possibly also exert a favourable effect on cardiac arrhythmias. The single dosage, which must be adapted to the patient's requirements and can, if necessary, be repeated several times, is 1–4 mg for adults and 0.5 mg for children.

Pharmaceutical precautions *Storage:* Capsules – protect from heat and moisture. Syrup – protect from heat. Keep containers tightly closed. Ampoules – protect from heat and light.

Dilutions: Syrup – dilutions down to 15 mg/5 ml can be prepared with boiled, distilled or de-ionised water. For dilutions below 15 mg/5 ml the recommended diluent is equal parts simple Syrup BP and freshly prepared Mucilage of Tragacanth BP. After dilution the solution should be used within a few days.

Legal category POM.

ANDURSIL*

Presentation *Andursil suspension:* White slightly thixotropic suspension odour and flavour of mint, containing the active ingredients

Aluminium hydroxide gel	≡ Al ₂ O ₃	200 mg
Magnesium hydroxide		200 mg
Aluminium hydroxide/magnesium carbonate co-dried gel		200 mg
Activated polymethylsiloxane		150 mg
		in each 5 ml

Andursil tablets: White, bevelled-edge, five-cornered tablets with the 'GEIGY' signet impressed on to one side, diameter approximately 2.1 cm, containing the active ingredients:

Aluminium hydroxide/magnesium carbonate co-dried gel	750 mg
Activated polymethylsiloxane	250 mg
	in each tablet

Uses *Antacid/antiflatulent:* Symptomatic relief of pain, discomfort, abdominal distension, heartburn (including heartburn of pregnancy), flatulence and vomiting associated with peptic ulceration, hiatus hernia, gastritis, functional gastro-intestinal disorders.

Dosage and administration Andursil is taken orally in either suspension or tablet form.

Andursil Suspension: 5–10 ml three or four times a day and at bedtime or when necessary.

Andursil Tablets: 1 or 2 tablets three or four times a day and at bedtime or when necessary.

Contra-indications, warnings, etc

Contra-indications: With the exception of hypophosphataemia, there are no known contra-indications to Andursil.

Precautions: As with other drugs, the administration of

Geigy Pharmaceuticals

Horsham

West sussex

RH12 4AB

ANAFRANIL*

Presentation The active ingredient, Clomipramine Hydrochloride, is presented as:

Two-tone blue/caramel-coloured capsules, hard gelatin size No. 4, imprinted GEIGY, each containing 50 mg.

Two-tone orange/caramel-coloured capsules, hard gelatin size No. 4, imprinted GEIGY, each containing 25 mg.

Two-tone yellow/caramel-coloured capsules, hard gelatin size No. 4, imprinted GEIGY, each containing 10 mg.

Orange flavoured and coloured syrup containing the equivalent of 25 mg clomipramine hydrochloride in 5 ml.

Ampoules of clear glass containing 25 mg clomipramine hydrochloride in 2 ml.

Uses *Antidepressant:* Endogenous depression, including manic-depressive, periodic and involutional depression. Reactive and neurotic depression. Obsessive and phobic states. Cataplexy associated with narcolepsy.

Dosage and administration *Administration:* Anaftranil is generally given orally in capsule or syrup form, but in severe cases it may be given intramuscularly or by intravenous infusion.

Dosage: Adults: Oral – 10 mg/day initially, increasing gradually to 30–150 mg/day, if required, in divided doses throughout the day or as a single dose at bedtime. Many patients will be adequately maintained on 30–50 mg/day. Higher doses may be needed in some patients, particularly those suffering from obsessional or phobic disorders.

Elderly: (patients over 60 years of age) 10 mg/day initially. The initial dose should be increased with caution under close supervision to a maximum of 75 mg daily.

Children: not established.

Intramuscular administration: In severe cases of depression or in patients who are unco-operative, treatment may be commenced with intramuscular injections of up to 6 × 25 mg ampoules daily, or even more in very severe cases. Once therapy has started to be effective, a change to oral dosage can be made.

Dosage: Intravenous infusion: Any standard giving set may be used but a cannula or fine needle with a flange which can be strapped in position should be chosen. Anaftranil ampoules may be diluted with either physiological saline or 5% Dextrose BP. The required dose of Anaftranil should be introduced into the infusion fluid with a sterile syringe and the contents should be agitated to ensure even distribution of the drug before infusion is commenced, into a forearm vein.

In the first instance a small dose of Anaftranil (25 mg or 50 mg) should be diluted in 200–500 ml of infusion fluid and infused over a period of two hours to assess tolerance. If satisfactory, the dose may be increased by 25 mg daily until an optimum therapeutic dose has been achieved. At the same time the bulk of fluid may be

reduced (to a minimum of 125 ml) and the duration of infusion decreased (to a minimum of 45 minutes).

On average the optimum therapeutic dose will be in the region of 100 mg but higher doses may be required in more severe depressions or in obsessional and phobic states.

Length of treatment: Infusions are usually given for 7–10 days to acutely depressed patients but severely depressed and obsessional and phobic patients may require more prolonged treatment. Regular daily treatment is preferable but when administration is inconvenient on certain days – for instance at weekends, oral therapy using double the intravenous dose may be substituted.

Changeover to oral therapy: Following a satisfactory response to infusion, the quantity of intravenous Anaftranil should be gradually reduced and oral therapy substituted. It is advisable to give double the maximum intravenous dosage orally until the patient's response is assured. Thereafter, a suitable maintenance dose, if considered necessary, can be selected.

Monitoring during treatment: During the course of infusion, patients should be carefully monitored for adverse effects. Particular attention should be paid to blood pressure recording, especially if there are any changes of position after conclusion of the infusion, as hypotension may occur. Patients often feel pleasantly drowsy during treatment and not infrequently fall asleep.

Contra-indications, warnings, etc

Contra-indications: Recent myocardial infarction, cardiac failure, any degree of heart block or other cardiac arrhythmias. Severe liver disease. Concurrent administration with monoamine oxidase inhibitors. Narrow angle glaucoma. Retention of urine.

Precautions: The elderly are particularly liable to experience adverse effects, especially agitation, confusion and postural hypotension. (See dosage).

Avoid if possible in patients with a history of epilepsy or with symptoms of bladder neck obstruction, e.g. prostatic hypertrophy.

Patients posing a high suicide risk require close initial supervision.

Tricyclic antidepressants potentiate the central nervous depressant action of alcohol.

Anaesthetics given during tri/tetracyclic antidepressant therapy may increase the risk of arrhythmias and hypotension. If surgery is necessary, the anaesthetist should be informed that a patient is being so treated.

As improvement may not occur during the first 2–4 weeks of treatment, patients should be closely monitored during this period.

Anaftranil may initially impair alertness. Patients should be warned of the possible hazard when driving or operating machinery.

Do not use during pregnancy, especially during the first and last trimesters, unless there are compelling reasons. There is no evidence as to drug safety in human

RYNACROM*

Presentation *Nasal Spray*: a plastic squeeze bottle containing a clear aqueous solution of Sodium Cromoglycate BP, 2.0% w/v.

Nasal Drops: a plastic dropper bottle containing a clear, aqueous solution of Sodium Cromoglycate BP, 2.0% w/v.

Cartridges: pink, transparent hard gelatin cartridges, each bearing the overprint 'RYNACROM'. Each cartridge contains 10 mg Sodium Cromoglycate BP in powder form for nasal insufflation.

Uses Rynacrom is indicated for the preventive treatment of allergic rhinitis (seasonal and perennial). Sodium cromoglycate inhibits the release from sensitised mast cells of histamine, SRS-A and chemotactic factors which mediate the allergic reaction. In the nose this inhibition of mediator release prevents the symptoms of rhinitis.

Dosage and administration Since therapy with Rynacrom is essentially preventive, it is important that the patient is instructed to maintain regular dosage, as distinct from using the drug intermittently to relieve symptoms.

Adults and children – Rynacrom Nasal Spray: 2 squeezes to each nostril six times daily.

Rynacrom Nasal Drops: Instil 2 drops into each nostril six times daily.

Rynacrom Cartridges: The contents of one cartridge are insufflated into each nostril up to four times daily. The first dose should be insufflated on rising and the last one immediately before retiring.

Contra-indications, warnings, etc There are no specific contra-indications.

Side-effects: Occasional irritation of the nasal mucosa may occur during the first days of use. In rare cases wheezing or tightness of the chest have been reported by patients.

Overdosage: No action other than medical supervision should be necessary.

Pharmaceutical precautions Store below 30°C. Rynacrom Nasal Spray and Nasal Drops should be protected from direct sunlight. Rynacrom Cartridges should be protected from light and kept dry.

Legal category P.

Package quantities Rynacrom Nasal Spray: bottle of 17.5 ml.

Rynacrom Nasal Drops: bottle of 15 ml.

Rynacrom Cartridges: containers of 100 cartridges.

Rynacrom Insufflators are supplied in separate containers. Instructions for use are supplied with each pack.

Further information A reduction in concomitant antihistamine therapy will often be possible.

An alternative presentation for nasal use of a 2% solution of Sodium Cromoglycate is available as Lomusol.

Product licence numbers

Rynacrom Nasal Drops: 0113/0040

Rynacrom Cartridges: 0113/5032

THEO-DUR* ▼

Presentation A slow release tablet containing Theophylline BP (anhydrous), designed to give therapeutic blood levels over 8–12 hours.

200 mg Tablet: Off-white mottled flat elliptical scored tablet.

300 mg Tablet: Off-white mottled bi-convex oblong scored tablet.

Uses As a bronchodilator in the symptomatic or prophylactic relief of bronchospasm associated with asthma and chronic bronchitis.

Dosage and administration

Adults: The initial recommended dose is one 300 mg tablet 12 hourly. This dose can be increased by $\frac{1}{2}$ tablet (150 mg) increments, if sufficient therapeutic effect is not obtained.

Alternatively, treatment can be started with one 200 mg tablet 12 hourly and increased by $\frac{1}{2}$ tablet (100 mg) increments until sufficient therapeutic effect is achieved or side effects occur.

Children: < 35 kg body weight: 100 mg ($\frac{1}{2}$ 200 mg tablet 12 hourly).

> 35 kg body weight: 200 mg 12 hourly.

If sufficient therapeutic effect is not achieved or side effects occur the dose can be adjusted up or down by 100 mg ($\frac{1}{2}$ 200 mg tablet).

Note: The tablet must not be crushed or chewed, but should be swallowed whole or as a half.

Contra-indications, warnings, etc

Contra-indications: None.

Side effects: Side effects of theophylline depend to a great extent on serum concentration and are frequent only at theophylline concentrations exceeding 20 mcg/ml. The Theo-Dur slow release formulation reduces fluctuation in serum levels of theophylline, thereby reducing the incidence of side effects.

Most common side effects are gastro-intestinal disturbances (nausea, vomiting and anorexia) which, in most cases, disappear on reducing the dose.

Severe side effects (cramps, convulsions and supraventricular tachycardia) may appear at very high serum concentration, in which case the medication should be discontinued.

If side effects appear, serum levels of theophylline should be monitored.

Pregnancy and lactation: No influence on the reproduction process is reported. Only small amounts of theophylline pass out to maternal milk. In therapeutic dose there is no risk of influence on the child.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities 100 tablets.

Further information Nil.

Product licence numbers 0113/0081 200 mg
0113/0082 300 mg

* Trade Mark

Overdosage: As Nalcrom is absorbed only to a very limited extent, no action other than medical observation should be necessary.

Pharmaceutical precautions Store in a dry place. Reclose the container tightly after use.

Legal category POM.

Package quantities Containers of 100 capsules.

Further information

1. If oral steroid therapy is to be reduced or withdrawn this should be done cautiously and not more rapidly than 10% per week.

2. Dosages of 2,000 mg daily have been used in some cases of proctocolitis.

3. Sodium cromoglycate has been administered as an enema in addition to oral use in the management of proctitis and ulcerative colitis. The powder contents of the capsules were dissolved in water prior to being given as a retention enema.

Product licence number 0113/0073.

OPTICROM* EYE DROPS

Presentation A clear colourless aqueous solution of Sodium Cromoglycate BP 2% w/v, with benzalkonium chloride 0.01% w/v.

Uses For the relief and treatment of acute allergic conjunctivitis such as hay fever, chronic allergic conjunctivitis and vernal kerato conjunctivitis. Sodium cromoglycate inhibits the release from sensitised mast cells of histamine, SRS-A and chemotactic factors which mediate the allergic reaction.

Dosage and administration One or two drops into each eye four times daily.

Contra-indications, warnings, etc Known hypersensitivity to benzalkonium chloride.

Pharmaceutical precautions Store below 30°C. Protect from direct sunlight.

Legal category POM.

Package quantities 10 ml.

Further information Discard any remaining contents four weeks after opening the bottle. As with other ophthalmic solutions containing benzalkonium chloride, soft contact lenses should not be worn during the treatment period.

Product licence number 0113/0039.

PARACODOL*

Presentation Large, white, soluble, effervescent tablets each containing:

Paracetamol BP 500 mg
Codeine Phosphate BP 8 mg

Uses For the treatment of pain, including muscular and rheumatic pains, headache, migraine, neuralgia, toothache, sore throat, period pains, aches and pains. Discomfort associated with influenza, feverishness and feverish colds.

Dosage and administration The tablets are to be dissolved in water before oral administration.

Adults: 1–2 tablets, which may be repeated every four to six hours with a maximum of 8 in 24 hrs.

Children: Aged 6–12 years: $\frac{1}{2}$ –1 tablet. Not more than 4 doses to be taken in 24 hours.

Under 6 years: To be taken only on the direction of the physician.

Contra-indications, warnings, etc **Precautions:** The tablet base is designed to be equivalent to 1.5 g Sodium Citrate BP equivalent to 352 mg or 15.3 millimole Na⁺. It should therefore be prescribed with caution in long term treatment of patients in whom a restricted salt intake is indicated.

Preparations containing paracetamol should be given with care to patients with impaired liver function.

Overdosage: It is unlikely that a toxic dose of large, effervescent tablets would be ingested. In the event of an overdose, the toxic effects of codeine may be reversed by the administration of naloxone injection. Symptoms of paracetamol overdose are often delayed for at least 24 hours but to prevent hepatic damage, treatment should be given as soon as possible and within 10 hours of ingestion. Treatment is by the administration of oral methionine, oral or intravenous acetylcysteine.

Pharmaceutical precautions Store in a cool dry place.

Legal category P.

Package quantities Boxes of 10 or 100 tablets.

Further information Nil.

Product licence number 0113/5076.

PSOROX* OINTMENT

Presentation A smooth, off-white ointment.

Active ingredients:

Salicylic Acid BP	3.0% w/w
Ammoniated Mercury BP	2.0% w/w
Purified Coal Tar Fractions	2.4% w/w

The coal tar fractions are therapeutically equivalent to 10% crude coal tar and comprise:

Phenol	4.2%	Toluene	8.3%
Pyridine	2.1%	Naphthalene	41.6%
α -Picoline	2.1%	O-Cresol	4.2%
Carbazole	10.4%	Quinoline	2.1%
Xylene	4.2%	Phenanthrene	16.6%
Anthracene	4.2%		

Uses Psoriasis.

Dosage and administration **Adults:** Rub in thoroughly, directly to affected area, twice a day.

Children: Not suitable for use by children.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Tubes of 25 g and 50 g.

Further information Nil.

Product licence number 0113/5081.

70 have been infused. This prevents over-dilution of clotting factors and maintains oxygen-carrying capacity. Where clotting factors are already reduced (e.g. in hypofibrinogenaemia or thrombocytopenia) correction of this condition must be undertaken prior to or concomitantly with the infusion.

Pharmaceutical precautions Do not store in excess of 25°C or expose to undue fluctuations in temperature. Do not use if cloudy or if a deposit is present. Discard any unused solution.

Legal category POM.

Package quantities Bottles of 500 ml.

Further information Nil.

Product licence numbers

Lomodex 70 in Dextrose 0113/5060

Lomodex 70 in Saline 0113/5061

LOMUSOL* NASAL SPRAY

Presentation A metered-dose presentation of a clear aqueous solution of Sodium Cromoglycate BP 2% w/v. The Lomusol pack contains a bottle of solution, and a pump; the appliance is assembled by the patient from these component parts.

Uses Lomusol is indicated for the preventative treatment of allergic rhinitis (seasonal and perennial).

Sodium cromoglycate inhibits the release from sensitised cells of histamine, SRS-A and chemotactic factors which mediate the allergic reaction. In the nose, this inhibition of mediator release prevents the symptoms of rhinitis.

Dosage and administration Since Lomusol therapy is essentially prophylactic, it is important that the patient is instructed to maintain regular dosage, as distinct from using the drug intermittently to relieve symptoms.

Adults and children: 1 squeeze to each nostril six times daily.

One squeeze delivers approximately 2.6 mg of sodium cromoglycate from the metered-dose device.

Contra-indications, warnings, etc

Contra-indications: There are no specific contra-indications.

Side-effects: Occasional irritation of the nasal mucosa may occur during the first days of use. In rare cases wheezing or tightness in the chest have been reported by patients.

Overdosage: No action other than medical supervision should be necessary.

Pharmaceutical precautions Store in a cool place and protect from direct sunlight.

Legal category P.

Package quantities 26 ml bottle and pump.

Further information Concomitant antihistamine therapy can often be reduced or discontinued when the allergic rhinitis has been brought under control.

Alternative presentations for nasal use of a 2% solution of sodium cromoglycate are available as Rynacrom Nasal Spray and Drops.

Product licence number 0113/0066.

NALCROM*

Presentation Nalcrom is a presentation of sodium cromoglycate for oral use. It is presented in clear/clear hard gelatin capsules printed Fisons 101 in black. Each capsule contains 100 mg sodium cromoglycate as a white powder.

Uses a) *Chronic inflammatory bowel disease:* As an adjuvant in the treatment of ulcerative colitis, proctitis and proctocolitis.

Nalcrom may be used in patients with a history of hypersensitivity to or intolerance of sulphasalazine.

Nalcrom may be used in conjunction with steroid therapy and sulphasalazine in the management of ulcerative colitis, proctitis and proctocolitis.

b) *Food allergy:* Food allergy (where adequate investigations have been performed to determine sensitivity to one or more ingested allergens) in conjunction with restriction of main causative allergens.

Sodium Cromoglycate inhibits the release from mast cells of histamine, SRS-A and chemotactic factors which mediate the allergic reaction. In gastro-intestinal disease the release of mediators causes a local inflammation which can either result in gastrointestinal symptoms or may allow absorption of antigenic material leading to systemic allergic reactions.

Dosage and administration *Dosage:*

a) *Chronic inflammatory bowel disease: Initial dose:*

Adults: 2 capsules four times daily before meals.

Children: From 2-14 years: 1 capsule four times daily before meals.

Maintenance dose: To prevent relapses dosage should be maintained indefinitely at 2 capsules four times daily in adults and 1 capsule four times daily in children.

b) *Food allergy: Initial dose: Adults:* 2 capsules four times daily before meals.

Children: From 2-14 years: 1 capsule four times daily before meals.

For adults and children if satisfactory control is not achieved within two to three weeks the dosage may be doubled but should not exceed 40 mg/kg/day.

Maintenance dose: Once a therapeutic response has been achieved the dose may be reduced to the minimum required to maintain the patient free of symptoms.

Patients who are unable to avoid allergenic foods under certain circumstances (e.g. school meals, restaurants) may be able to protect themselves against the effect of these foods by taking a single dose of Nalcrom 15 minutes before the meal. The optimum dosage will need to be determined for each patient and a suitable starting dose would be 200 mg in adults and 100 mg in children.

Administration: The capsules may be swallowed whole or the powder contents may be dissolved in a small quantity of very hot water and diluted with cold water to drink. Administration as a solution in water is probably the method of choice in food allergy.

Contra-indications, warnings, etc

Contra-indications: There are no specific contra-indications.

Warnings: The safety of Nalcrom in pregnancy and for the treatment of children under two years has not yet been established.

Side-effects: Nausea, skin rashes and joint pains have been reported in a few cases.

Dosage and administration

1. *Crush syndrome, fat embolism, severe burns and mesenteric infarction:* 1st day: 500–1,000 ml Lomodex 40 should be given by i.v. infusion, followed by a further 1,000–2,000 ml given slowly over the next 24 hours. 2nd day: 1,000–2,000 ml by slow infusion. 3rd day: 500–1,000 ml by slow infusion (N.B. larger doses may be required in burns.)

2. *Vascular surgery:* Before surgery: 500 ml by continuous infusion. During surgery: a further 500 ml. After surgery: 500 ml daily for at least three days.

3. *Extra-corporeal circulation procedures:* Lomodex 40 is added to the perfusion fluid (not more than 20 ml Lomodex 40/kg body weight).

4. *Before angiography, e.g. aortography:* 10–15 ml Lomodex 40/kg body weight is administered by intravenous infusion over 30 minutes.

5 and 6. *Plastic surgery and vascular insufficiency:* The rate of infusion and dosage will depend on clinical circumstances, bearing in mind the precautions indicated below.

7. *Peripheral vascular disorders:* 500 ml are given every 12 hours until 2,000 ml have been infused. Repeat infusions are required two to four times a year.

8. *Shock:* A rapid infusion of 500 ml followed by a further 500–1,000 ml over the next three to five hours, depending on the degree of shock.

Contra-indications, warnings, etc *Anaphylactoid reactions* occur rarely. They are more common and may be more severe in patients with a history of asthma.

The most frequently observed signs of such reactions are hypotension and bronchospasm, progressing on very rare occasions to cardiac arrest. In addition, skin manifestations such as erythema and urticaria may be seen.

In view of the above, it is essential to observe patients closely throughout the infusion, particularly during the first few minutes. If there is any suspicion of an anaphylactoid reaction, treatment with Lomodex should be discontinued *immediately* and appropriate resuscitative measures instituted.

Lomodex 40 should not be used in patients with renal failure, with blood urea levels above 10 mmol/litre (60 mg/100 ml) or whose urine output cannot be maintained above 1,500 ml/day.

Renal function should be monitored, especially when treatment is prolonged for more than two to three days consecutively. Lomodex 40 should be withdrawn if the specific gravity of the urine rises above 1.045 or if there is a reduced output of urine. If oliguria occurs, urine output should be stimulated with diuretics and intravenous fluids as appropriate.

Dehydration should preferably be corrected prior to, or at least, concomitantly with, the infusion of Lomodex 40. Until dehydration is corrected, the infusion rate should not exceed 500 ml/hour.

In surgery, dosage for any one infusion should not exceed 20 ml Lomodex 40/kg body weight because of the risk of capillary oozing. When clotting factors are already reduced (e.g. in hypofibrinogenaemia or thrombocytopenia) correction of the condition must be undertaken prior to, or concomitantly with, infusion of Lomodex 40.

With Lomodex 40 there is no necessity to take blood for cross-matching prior to infusion as there is no interference if a sample is subsequently required.

Pharmaceutical precautions Do not store in excess

of 25°C or expose to undue fluctuations in temperature. Do not use if cloudy or if a deposit is present. Discard any unused solution.

Legal category POM.

Package quantities Bottles of 500 ml.

Further information Nil.

Product licence numbers

Lomodex 40 in Dextrose 0113/5062

Lomodex 40 in Saline 0113/5063

LOMODEX* 70 IN DEXTROSE

LOMODEX* 70 IN SALINE

Presentation *Lomodex 70 in Dextrose:* a clear, almost colourless, slightly viscous liquid. Dextran 70 Injection BP in 5% Dextrose. A sterile solution containing 6% w/v dextrans of weight average molecular weight 70,000 in 5% w/v Dextrose Injection BP.

Lomodex 70 in Saline: a clear, almost colourless, slightly viscous liquid. Dextran 70 Injection BP in 0.9% sodium chloride. A sterile solution containing 6% w/v dextran of weight average molecular weight 70,000 in Sodium Chloride Injection BP.

Uses

1. Prevention of post-operative deep vein thrombosis
2. Short-term blood volume expansion.

Dosage and administration

1. *Prevention of post-operative deep vein thrombosis* Continuous infusion before, during and after surgery. A total infusion of 1,000 ml over a period of six hours.

2. *Short-term blood volume expansion: Haemorrhage:* In moderate blood loss 500 ml are infused rapidly taking 15 minutes. A further 500 ml are given more slowly taking 30–45 minutes. In severe haemorrhage 1,000 ml are infused as rapidly as possible. A further 500 ml may be given more slowly, depending on the clinical condition of the patient and the availability of cross-matched blood.

Crush injuries: The loss of plasma proteins into injured tissues and the consequent attraction of water out of the circulation may be combated by the infusion of 500–1,500 ml of Lomodex 70. The rate of infusion is dictated by the degree of shock. Where this is severe, rapid infusion is necessary.

Burns: As a guiding principle, up to 3,000 ml of Lomodex 70 may be given in the first 36–48 hours. Electrolytes, dextrose and possibly blood will also be required according to the clinical situation.

Contra-indications, warnings, etc *Anaphylactoid reactions* occur rarely. They are more common and may be more severe in patients with a history of asthma. The most frequently observed signs of such reactions are hypotension and bronchospasm, progressing on very rare occasions to cardiac arrest. In addition, skin manifestations such as erythema and urticaria may be seen.

In view of the above, it is essential to observe the patients closely throughout the infusion, particularly during the first few minutes. If there is any suspicion of an anaphylactoid reaction, treatment with Lomodex should be discontinued *immediately* and appropriate resuscitative measures instituted.

In continuing haemorrhage, whole blood or packed cells may be indicated after 1,000–1,500 ml of Lomodex

ate and a plastic mouthpiece. Instructions for use are supplied with each pack.

Further information

Concomitant bronchodilator therapy: Where a concomitant aerosol bronchodilator is prescribed, it is recommended that this be administered prior to the Intal inhaler.

Concomitant steroid therapy: In patients currently treated with steroids the addition of Intal Inhaler to the regimen may make it possible to reduce the maintenance dose or to discontinue steroids completely. The patient must be carefully supervised while the steroid dose is reduced; a rate of reduction of 10% weekly is suggested.

If reduction of steroid dosage has been possible Intal inhaler should not be withdrawn until steroid cover has been re-instituted.

Use in pregnancy: As with all medication particular caution must be exercised during the first trimester of pregnancy.

Product licence number 0113/0080.

INTAL* NEBULISER SOLUTION

Presentation Intal Nebuliser Solution is presented in ampoules containing Sodium Cromoglycate BP 20 mg in 2 ml of a clear colourless sterile aqueous solution.

Uses Intal Nebuliser Solution is indicated for the preventive treatment of bronchial asthma which may be due to allergy, exercise, cold air or chemical and occupational irritants. Sodium cromoglycate inhibits the release from sensitised mast cells of histamine, SRS-A and chemotactic factors which mediate the allergic reaction. In the lung this inhibition of mediator release prevents both the immediate and late asthmatic response (i.e. Type I and Type III responses) to immunological stimuli. Sodium cromoglycate also prevents the bronchoconstriction caused by exercise, cold air and chemical irritants.

Dosage and administration Intal Nebuliser Solution should be administered from a power-operated nebuliser at an adequate flow rate, via a face mask or mouthpiece. Information on suitable power operated nebulisers is available on request. Hand operated nebulisers are not suitable for the administration of Intal Nebuliser Solution.

Dosage: Since Intal Nebuliser Solution therapy is essentially preventive, it is important that regular dosage is maintained, as distinct from intermittent use to relieve symptoms.

Adults and children: The contents of one ampoule are administered by nebulisation four times a day, i.e. night and morning and at intervals of 3-6 hours. In severe cases frequency of administration may be increased to 5 or 6 times daily.

Contra-indications, warnings, etc

Contra-indications: There are no specific contra-indications. Intal Nebuliser Solution must not be given by injection.

Side-effects: Occasional irritation of the throat and trachea, and in rare cases severe bronchospasm, have been reported with powder forms of sodium cromoglycate.

Overdosage: No action other than medical observation should be necessary.

Withdrawal of Intal Nebuliser Solution therapy: Since

sodium cromoglycate acts prophylactically, it is important to continue treatment in those patients who benefit. If it is necessary to withdraw Intal Nebuliser Solution this should be done progressively over a period of one week. Symptoms of asthma may recur.

Use in pregnancy: As with all medication, particular caution must be exercised during the first trimester of pregnancy.

Pharmaceutical precautions Store in a cool place protected from sunlight. Should the physician decide to mix Intal Nebuliser Solution with other agents, the mixture should be prepared just prior to use and discarded if any turbidity develops. Any unused solution should be discarded immediately and the chamber of the nebuliser thoroughly cleaned.

Legal category POM.

Package quantities Box containing 48 x 2 ml ampoules.

Further information **Concomitant steroid therapy:** In patients currently treated with steroids, the addition of Intal Nebuliser Solution to the regime may make it possible to reduce the maintenance dose or to discontinue steroids completely. The patient must be carefully supervised while the steroid dose is reduced; a rate of reduction of 10% weekly is suggested. An increase in steroid dosage may be necessary if symptoms increase and at times of infection, severe antigen challenge or stress.

If reduction of steroid dosage has been possible, Intal Nebuliser Solution should not be withdrawn until steroid cover has been re-instituted.

Concomitant bronchodilator therapy: If bronchodilators are used concomitantly, patients may find that the frequency of bronchodilator usage can be reduced as their asthma is stabilised with Intal Nebuliser Solution.

Product licence number 0113/0068.

LOMODEX* 40 IN DEXTROSE LOMODEX* 40 IN SALINE

Presentation *Lomoxed 40 in Dextrose:* a clear, almost colourless, slightly viscous liquid. Dextran 40 Injection BP in 5% dextrose. A sterile solution containing 10% w/v dextrans of weight average molecular weight 40,000 in 5% w/v Dextrose Injection BP.

Lomoxed 40 in Saline: a clear, almost colourless, slightly viscous liquid. Dextran 40 Injection BP in 0.9% sodium chloride. A sterile solution containing 10% w/v dextrans of weight average molecular weight 40,000 in Sodium Chloride Injection BP.

Uses Lomoxed 40 solutions are given by intravenous infusion for the prevention and treatment of intravascular 'sludging':

1. In the management of the crush syndrome, fat embolism, severe burns and mesenteric infarction.
2. In vascular surgery.
3. In extra-corporeal circulation procedures.
4. Before angiography.
5. In plastic surgery e.g. skin grafts.
6. Vascular insufficiency.
7. Peripheral vascular disorders.
8. Short-term plasma expander in shock.

Uses Intal Compound is indicated for the preventive treatment of bronchial asthma which may be due to allergy, exercise, cold air or chemical and occupational irritants. Sodium cromoglycate inhibits the release from sensitised mast cells of histamine, SRS-A and chemotactic factors which mediate the allergic reaction. In the lung this inhibition of mediator release prevents both the immediate and late asthmatic response (i.e. Type I and Type III responses) to immunological stimuli. Sodium cromoglycate also prevents the bronchoconstriction caused by exercise, cold air and chemical irritants. Isoprenaline sulphate is included to offset the transient bronchospasm which occurs in some patients on inhalation of a fine dry powder.

Dosage and administration Intal Compound is presented in a single dose cartridge, the 'Spincap', for use in a specially developed turbo-vibratory inhaler, the 'Spinhaler'. Inhalation of the drug is controlled by the patient's inspiratory effort. Intal Compound is not effective if the 'Spincap' is swallowed because prevention of the asthmatic attack depends upon local application to the lung.

Dosage: Since Intal Compound therapy is essentially preventive, it is important that the patient is instructed to maintain regular dosage, as distinct from inhaling the drug intermittently to relieve symptoms.

Adults and children: The normal dose is one 'Spincap' four times daily, i.e. one night and morning and at intervals of 3-6 hours in between. It may be necessary to increase this to 6-8 times daily in more severe cases or during periods of severe antigen challenge. Additional doses may be taken before exertion to prevent exercise induced asthma or before exposure to other trigger factors.

When the asthmatic condition is stabilised, it may be possible to reduce the dosage provided that adequate control of the asthma is maintained.

Contra-indications, warnings, etc

Contra-indications: There are no specific contra-indications.

Side-effects: Occasional irritation of the throat and trachea may occur. In rare cases severe bronchospasm has been reported, usually at the beginning of treatment, necessitating withdrawal of the drug.

Precautions: The precautions normally applying to isoprenaline should be observed. Where concomitant bronchodilator therapy is prescribed, the possibility of isoprenaline overdose should be remembered.

Overdosage: No action other than medical observation should be necessary.

Withdrawal of Intal Compound therapy: Since Intal Compound acts prophylactically, it is important to continue treatment in those patients who benefit. If it is necessary to withdraw Intal Compound, this should be done progressively over a period of one week. Symptoms of asthma may recur.

Use in pregnancy: As with all medications, particular caution must be exercised during the first trimester of pregnancy.

Pharmaceutical precautions Store in a moisture-proof container in a cool, dry place protected from light.

Legal category POM.

Package quantities Containers of 50 'Spincap' cartridges are available singly or in packs of two. 'Spinhaler'

in insufflators are supplied in individual containers. Instructions for use are supplied with each pack.

Further information *Concomitant steroid therapy:* In patients currently treated with steroids, the addition of Intal Compound to the regime may make it possible to reduce the maintenance dose or to discontinue steroid completely. The patient must be carefully supervised while the steroid dose is reduced; a rate of reduction of 10% weekly is suggested. An increase in steroid dosage may be necessary if symptoms increase and at times of infection, severe antigen challenge or stress.

If reduction of steroid dosage has been possible Intal Compound should not be withdrawn until steroid cover has been re-instituted.

Concomitant bronchodilator therapy: If additional bronchodilators are used concomitantly, patients may find that the frequency of bronchodilator usage can be reduced as their asthma is stabilised with Intal Compound.

Product licence number 0113/5023.

INTAL* INHALER ▼

Presentation Metered dose pressurised aerosol delivering 200 inhalations each containing a total of 1.0 mg Sodium Cromoglycate, BP.

Uses Intal Inhaler is indicated for the treatment of bronchial asthma, including the prevention of exercise induced asthma.

Dosage and administration Since Intal Inhaler therapy is essentially preventative it is important that the patient is instructed to maintain regular dosage, as distinct from inhaling the drug intermittently to relieve symptoms.

Adults and Children: Two inhalations of the inhaler four times daily for routine prevention of asthma. The dose may be increased to two inhalations six or eight times daily in more severe cases or during periods of severe antigen challenge. Additional doses before exercise may also be taken.

Contra-indications, warnings, etc

Contra-indications: There are no specific contra-indications.

Side-effects: No significant side-effects have been reported. Although it has not been reported with Intal Inhaler, where Intal Spincaps have been administered via the Spinhaler, rare cases involving severe bronchospasm have been reported.

Overdosage: No action other than medical observation should be necessary.

Withdrawal of Intal Inhaler Therapy: Since the therapy is essentially prophylactic it is important to continue therapy in those patients who benefit. If it is necessary to withdraw this treatment, it should be done progressively over a period of one week. Symptoms of asthma may recur.

Pharmaceutical precautions Store the inhaler in a cool place. The Intal Inhaler canister is pressurised. The canister should be protected from direct sunlight and must not be punctured or burnt, even when empty.

Legal category POM.

Package quantities Each pack contains a canister delivering 200 metered inhalations of sodium cromogly-

Nevertheless, as iron deficiency anaemia occurring in the first trimester can be adequately treated with oral iron, or by a series of intramuscular injections of Imferon not exceeding 5 ml per day, it is recommended that total dose infusion and large intravenous doses of undiluted Imferon be reserved for use in the second and third trimesters.

Adverse reactions: Rarely, anaphylactoid reactions (sometimes severe, including fatal) have been reported; also occasional transient reactions such as urticaria and other rashes; arthralgia; lymphadenopathy; pyrexia. Local phlebitis at injection site (i.v. injection, Total Dose Infusion). Possible exacerbation of joint pain and swelling in rheumatoid arthritis.

Pharmaceutical precautions Protect from heat. Do not freeze.

Legal category POM.

Package quantities Ampoules of 2 ml (100 mg Fe) in boxes of 10 and 100.

Ampoules of 5 ml (250 mg Fe) in boxes of 5 and 50. TDI ampoules of 20 ml (1,000 mg Fe) in boxes of 5.

Further information The intramuscular and subcutaneous injection of iron-carbohydrate complexes in very large doses under experimental conditions in animals produced sarcomas in rats, mice, rabbits, possibly hamsters but not in guinea-pigs. Cumulative information and independent assessment indicates if there is a risk, it is minimal. Iron-dextran complex (Imferon) contains very little free ionic iron, allowing initially high serum iron levels without completely saturating or exceeding the iron binding capacity. The absence of untoward reactions to high serum levels of iron and low toxicity is due to the very high stability of the iron-dextran complex.

Product licence number 0113/5073.

INTAL*

Presentation Intal is a presentation for inhalation of sodium Cromoglycate BP 20 mg in micronised powder form. It is presented in a yellow/colourless, transparent, hard gelatin cartridge, bearing the overprint 'FISONS INTAL P'.

Uses Intal is indicated for the preventive treatment of bronchial asthma which may be due to allergy, exercise, cold air or chemical and occupational irritants. Sodium cromoglycate inhibits the release from sensitised mast cells of histamine, SRS-A and chemotactic factors which mediate the allergic reaction. In the lung this inhibition of mediator release prevents both the immediate and late asthmatic response (i.e. Type I and Type III responses) to immunological stimuli. Sodium cromoglycate also prevents the bronchoconstriction caused by exercise, cold air and chemical irritants.

Dosage and administration Intal is presented in a single dose cartridge, the 'Spinicap', for use in a specially developed turbo-vibratory inhaler, the 'Spinhaler'. Inhalation of the drug is controlled by the patient's inspiratory effort. Intal is not effective if the 'Spinicap' is swallowed because the prevention of the asthmatic attack depends upon local application to the lung.

Dosage: Since Intal therapy is essentially preventive, it is important that the patient is instructed to maintain regular dosage, as distinct from inhaling the drug intermittently to relieve symptoms.

Adults and children: The normal dose is one 'Spinicap' four times daily, i.e. one night and morning and at intervals of 3-6 hours in between. It may be necessary to increase this to 6-8 times daily in more severe cases or during periods of severe antigen challenge. Additional doses may be taken before exertion to prevent exercise induced asthma or before exposure to other trigger factors.

When the asthmatic condition is stabilised, it may be possible to reduce the dosage provided that adequate control of the asthma is maintained.

Contra-indications, warnings, etc

Contra-indications: There are no specific contra-indications.

Side-effects: Occasional throat irritation or coughing may occur in some patients sensitive to the inhalation of a dry powder. These can usually be overcome by changing to Intal Compound. In rare cases, severe bronchospasm has been reported, usually at the beginning of treatment, necessitating withdrawal of the drug.

Overdosage: No action other than medical observation should be necessary.

Withdrawal of Intal therapy: Since Intal acts prophylactically, it is important to continue treatment in those patients who benefit. If it is necessary to withdraw Intal, this should be done progressively over a period of one week. Symptoms of asthma may recur.

Use in pregnancy: As with all medications, particular caution must be exercised during the first trimester of pregnancy.

Pharmaceutical precautions Store in a moisture-proof container in a cool, dry place protected from light.

Legal category POM.

Package quantities Containers of 50 'Spinicap' cartridges are available singly or in packs of two. 'Spinhaler' insufflators are supplied in individual containers. Instructions for use are supplied with each pack.

Further information *Concomitant steroid therapy:* In patients currently treated with steroids, the addition of Intal to the regime may make it possible to reduce the maintenance dose or to discontinue steroids completely. The patient must be carefully supervised while the steroid dose is reduced; a rate of reduction of 10% weekly is suggested. An increase in steroid dosage may be necessary if symptoms increase and at times of infection, severe antigen challenge or stress.

If reduction of steroid dosage has been possible Intal should not be withdrawn until steroid cover has been re-instituted.

Concomitant bronchodilator therapy: If bronchodilators are used concomitantly, patients may find that the frequency of bronchodilator usage can be reduced as their asthma is stabilised with Intal.

Product licence number 0113/5022.

INTAL* COMPOUND

Presentation Intal Compound is a presentation for inhalation of Sodium Cromoglycate BP 20 mg (micronised) and Isoprenaline Sulphate BP 0.1 mg in powder form. It is presented in an orange/colourless, transparent, hard gelatin cartridge bearing the overprint 'FISONS 670C'.

when ergometrine is given alone and the effect is approximately that of intravenous ergometrine.

As an aid to local anaesthesia in ophthalmology: The solution employed consists of a 2% solution of procaine hydrochloride and 0.4% potassium sulphate. One drop of adrenaline hydrochloride (1:1,000) and approximately 150 international units of Hyalase are added to each 5 ml of the solution.

Two further drops of adrenaline are added for cone injections if this is not contra-indicated.

As an aid to local anaesthesia in fracture reduction:

For Colles' fracture: 20 ml of 1% procaine are mixed with 1,500 international units of Hyalase. Two injections are made: the bulk of the solution is put directly into the fracture haematoma from the extensor aspect of the forearm, and 2-3 ml are infiltrated around the ulnar styloid process. The anaesthetic solution diffuses rapidly all around the injured area and the fracture can be manipulated as soon as the needle is withdrawn.

For Pott's fracture: 40 ml of 1% procaine are mixed with 1,500 international units of Hyalase.

Radiography: The contents of 1 ampoule of Hyalase are dissolved in 1 ml water for injections (a fresh solution must be prepared on each occasion).

Half a millilitre of Hyalase solution is then added to 5 ml of 35% diiodone solution and made up to 15 ml with water for injections.

Fifteen millilitres of the mixture are injected subcutaneously in the scapular region and are followed immediately by a further 15 ml at another site, e.g. the contralateral scapular region.

The area of injection is massaged vigorously to aid dispersion. Normally renal secretion commences five minutes after injection; adequate concentration is obtained in 24-25 minutes and is equal to that obtained by the intravenous method.

Note - The volumes stated are also applicable to children aged from a few weeks to five years provided that renal function is not grossly impaired.

Contra-indications, warnings, etc

Contra-indications: Not to be used to reduce the swelling of bites or stings, or at sites where infection or malignancy is present.

Not to be used for intravenous injections.

Pharmaceutical precautions Store in a cool dry place. Solutions of Hyalase rapidly lose activity and should be used within 12-24 hours of preparation.

Legal category POM.

Package quantities Boxes of 5, 20 and 100 ampoules.

Further information Nil.

Product licence number 0113/5021.

IMFERON®

Presentation Imferon is presented as ampoules containing a dark brown, slightly viscous solution containing iron (50 mg/ml) in the form of a complex of ferric hydroxide with a low molecular weight dextran in a 0.9% sodium chloride solution for injection.

Uses For the rapid and complete correction of proven iron deficiency.

Dosage and administration *Routes of administration:* A series of deep intramuscular injections.

A series of intravenous injections.

One or two large-volume intravenous injections.

Continuous intravenous infusion diluted with normal saline or 5% dextrose solution.

Recommended dosage: Adults and children: The total dose of Imferon required is calculated for each patient individually and is dependent on body weight and haemoglobin level. Tables are provided with each pack of ampoules, and dosage calculators are available on request.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to the product.

The Total Dose Infusion (TDI) method of administration should not be used for patients with a history of asthma. Imferon should not be used in the acute phase of infectious kidney disease.

Warnings: The preparation should be used with extreme care in patients with serious impairment of liver function.

Intramuscular use: In patients with a known history of allergy or chronic infection, a graded series of injection: is strongly recommended, e.g. 0.5 ml, 1 ml then 2 ml until the course is complete.

Intravenous use: Test dose: Undiluted Imferon: Prior to receiving their first Imferon therapeutic dose all patients should be given a *slowly administered* intravenous test dose of not more than 0.5 ml Imferon diluted with patient's own blood. Acute anaphylactoid reactions in these circumstances are usually evident within a few minutes, and this is the *minimum* time period of observation prior to completing the dose - still under strict medical supervision and by slow injection not exceeding 1 ml per minute.

A time interval of an hour or more between test dose and subsequent administration of the complete dose may be desirable in individual circumstances.

The total dose may be divided and given as a series of intravenous injections adopting the same technique.

Test dose: Total dose infusion (TDI): The initial rate of infusion should not exceed 5 drops per minute for 15 minutes *under strict medical supervision*. If this test dose is well tolerated the rate of infusion may be increased to 45 to 60 drops per minute.

Outpatients should be kept under supervision for about an hour after infusion is complete before returning home.

As a high incidence of post-infusion arthralgia has been reported after the total dose infusion method in rheumatoid arthritis, this method of administration should only be used when other forms of iron therapy have been found to be unsuccessful in such patients.

If at any time during the administration of Imferon by TDI or undiluted by the intravenous route signs of hypersensitivity reaction or intolerance are detected stop administration immediately and institute appropriate treatment.

Patients with a history of allergy should be under effective antihistamine therapy at the time of intravenous administration/infusion.

Use in pregnancy: Studies in non-anaemic pregnant animals have indicated that at high single doses of Imferon > 2.5 ml/kg, teratogenic effects may occur. No such effects have been produced at lower levels of 1 ml/kg. For clinical human use the highest dose normally required is in the order of 1 ml/kg or less.

Pharmaceutical precautions Store in cool place. Protect from freezing. Discard four weeks after first opening container.

Legal category POM.

Package quantities Dropper bottle of 5 ml.

Further information Nil.

Product licence number 0113/5090.

FRAMYGEN® EYE OINTMENT

Presentation A smooth, pale yellow ointment containing Framycetin Sulphate BP 0.5% w/w.

Uses The treatment of blepharitis and styes, blepharconjunctivitis, infected conjunctivitis and infected corneal abrasions.

Dosage and administration Direct application to the eye four to six times daily.

Contra-indications, warnings, etc

Contra-indications: Known hypersensitivity to framycetin.

Warnings: Cross sensitivity can occur in neomycin sensitive patients.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Tube of 3.5 g.

Further information Nil.

Product licence number 0113/5069.

GENISOL®

Presentation A clear, golden-yellow liquid containing sodium sulphosuccinated undecylenic monoalkolamide 1% w/v, purified coal-tar fractions 0.25% w/v designed to be therapeutically equivalent to 2% Prepared Coal Tar 3P and comprising:

Phenol	8% w/w	o-Cresol	8% w/w
Quinoline	4% w/w	Pyridine	2% w/w
o-Picoline	2% w/w	Toluene	16% w/w
Xylene	8% w/w	Phenanthrene	32% w/w
Carbazole	20% w/w		

Uses Seborrhoeic dermatitis of the scalp (dandruff) and psoriasis of the scalp.

Dosage and administration To be used once per week or more frequently if required, in the manner of a shampoo. Stir about 10 ml of Genisol into half a tumblerful of warm water. Wet the hair thoroughly, apply half the solution and work into the scalp with the fingers. Rinse and repeat the application. Finally, rinse the hair thoroughly in clean water.

Contra-indications, warnings, etc When washing the hair, care should be taken to keep the solution away from the eyes.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Bottles of 58 ml, 250 ml and 500 ml.

Further information Nil.

Product licence number 0113/5020.

HYALASE®

Presentation A white, fluffy, odourless powder. Each ampoule contains 1,500 international units of Hyaluronidase BP (Ovine).

Uses Hyaluronidase has a temporary and reversible depolymerising action on the polysaccharide hyaluronic acid which is present in the intracellular matrix of connective tissue. This action allows the rapid dispersal and absorption of substances given by subcutaneous or intramuscular injection. Hyaluronidase also facilitates the dispersal of extravasated fluid and haematomatous swellings.

Dosage and administration Adults: *In hypodermoclysis:* a two-way subcutaneous infusion set is required with the fluid container supported about 1 metre above the patient. Suitable hypodermic needles are attached to the connecting tubes after any contained air has been expelled. The needles are then inserted into the subcutaneous tissues at selected sites and the fluid allowed to run in by gravity. The contents of one ampoule of Hyalase (1,500 international units), dissolved in one ml of water for injections, are injected through the rubber tubing about 2 cm from each needle, at the beginning of the infusion.

When this method is employed, approximately 200 ml of fluid can be administered in 20 minutes.

Repeated infusions may be given as required, but it is advisable to change the site of injection.

Injection may alternatively be given from a syringe directly into a site into which 1 ml water for injections containing 1,500 international units of Hyalase has previously been injected. The needle should be maintained in the site adopted throughout the procedure which, in this case, should not be unduly prolonged.

It is not advisable to raise the temperature of the fluid prior to infusion since this has been observed to reduce the rate of absorption.

Site of injection. The possible sites of administration are numerous, irrespective of the position of the patient. Choice may be made, for example, from the axillae, pectoral regions, subscapular and trunk areas, thighs and calves.

In general 1,500 international units of Hyalase are sufficient for the administration of 500–1,000 ml of most fluids. In the case of whole blood, however, 3,000 units may be required.

Obstetric anaesthesia: The anaesthetic mixture is prepared as follows:—

Hyalase – 1,500 international units.

Adrenaline hydrochloride – 0.5 ml of 1:1,000 dilution.

Procaine hydrochloride – 30 ml of 1% solution.

Heins' method is as follows: The needle is passed horizontally to the ischial spine, and 5 ml of the solution is deposited here to anaesthetise the pudendal nerve as it enters Alcock's canal. Next, 5 ml of the mixture is infiltrated in the superior portion of the labia minora to anaesthetise the perineal branches of the ilioinguinal nerve. The same procedure is carried out on both sides of the perineum.

Prevention of post-partum haemorrhage: 1,500 international units of Hyalase are dissolved in 1 ml of a solution containing 0.5 mg ergometrine for intramuscular injection. The injection is given in the thigh at the moment of crowning or delivery of the foetal head. When ergometrine is given with Hyalase in this way, the oxytocic effect is apparent 3–4 minutes earlier than

corticosteroids can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for long periods.

In infants, long-term continuous topical therapy should be avoided. Adrenal suppression can occur even without occlusion.

Cross sensitivity can occur in neomycin sensitive patients.

Pharmaceutical precautions Store in a cool place. Protect from freezing. Shake well before use. Discard two weeks after first opening container.

Legal category POM.

Package quantities Dropper bottle of 5 ml.

Further information Nil.

Product licence number 0113/5089.

FRAMYCORT* EYE OINTMENT

Presentation Smooth, pale yellow ointment containing:

Framycetin Sulphate BP	0.5% w/w
Hydrocortisone Acetate BP	0.5% w/w

Uses The treatment of superficial bacterial eye infections, conjunctivitis, blepharitis, marginal corneal ulceration.

Dosage and administration To be applied to the eye two or three times daily.

Contra-indications, warnings, etc

Contra-indications: Viral infections. Known hypersensitivity to framycetin.

Precautions: In pregnant animals, administration of corticosteroids can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for long periods.

In infants, long-term continuous topical therapy should be avoided. Adrenal suppression can occur even without occlusion.

Cross sensitivity can occur in neomycin sensitive patients.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Tube of 3.5 g.

Further information Nil.

Product licence number 0113/5065.

FRAMYCORT* OINTMENT

Presentation Off-white ointment containing:

Framycetin Sulphate BP	0.5% w/w
Hydrocortisone Acetate BP	0.5% w/w

Uses Subacute and chronic eczema-dermatitis complicated by secondary infection, seborrhoeic dermatitis, anogenital pruritus.

Dosage and administration *Topical application:* Rub in gently and thoroughly two to three times daily,

leaving a light surface layer over the affected area. Cover with a light dressing.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to framycetin.

Precautions: In pregnant animals, administration of corticosteroids can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroid should not be used extensively in pregnancy, i.e. in large amounts or for long periods.

In infants, long-term continuous topical therapy should be avoided. Adrenal suppression can occur even without occlusion.

Cross sensitivity can occur in neomycin sensitive patients.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Tube of 15 g.

Further information Nil.

Product licence number 0113/5067.

FRAMYGEN* CREAM

Presentation Smooth, white cream containing Framycetin Sulphate BP 0.5% w/w.

Uses All uncomplicated bacterial skin infections including: sycosis barbae, impetigo and other pyogenic infections.

Dosage and administration Topical application smeared directly on to lesions or as a spread on dressing two to three times a day.

Contra-indications, warnings, etc

Contra-indications: Known hypersensitivity to framycetin.

Warnings: Cross sensitivity can occur in neomycin sensitive patients.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Tube of 15 g.

Further information Nil.

Product licence number 0113/5068.

FRAMYGEN* EYE AND EAR DROPS

Presentation A clear, very pale fawn coloured fluid containing Framycetin Sulphate BP 0.5% w/w.

Uses *In ophthalmology:* Treatment of styes, blepharitis, conjunctivitis and other superficial eye infections, corneal abrasions.

In otology: Otitis externa.

Dosage and administration To be applied to the eye or into the auditory canal, 1-4 drops three to four times daily, or as directed by the physician.

Contra-indications, warnings, etc

Contra-indications: Known hypersensitivity to framycetin or benzalkonium chloride.

Warnings: Cross sensitivity can occur in neomycin sensitive patients.

njection BP in 5% dextrose. A sterile solution containing 6% w/v dextrans of weight average molecular weight 10,000 in 5% w/v Dextrose Injection BP.

Dextraven 110 in Saline: a clear, almost colourless, slightly viscous liquid. Dextran 110 Injection BP in 0.9% sodium chloride. A sterile solution containing 6% w/v dextrans of weight average molecular weight 110,000 in Sodium Chloride Injection BP.

Dextraven 150 6% in Dextrose: a clear, almost colourless, slightly viscous liquid. A sterile solution containing 6% w/v dextrans of weight average molecular weight 150,000 in 5% w/v Dextrose Injection BP.

Dextraven 150 6% in Saline: a clear, almost colourless, slightly viscous liquid. A sterile solution containing 6% w/v dextrans of weight average molecular weight 150,000 in Sodium Chloride Injection BP.

Uses For the restoration and maintenance of blood volume where this has been reduced as a result of haemorrhage, extravasation of blood or plasma, accidental or surgical wounds, and in burns. Prophylactically, in major surgery to maintain blood volume and pressure during prolonged operations.

Dosage and administration *Haemorrhage:* In moderate blood loss 500 ml are infused rapidly, taking 15 minutes. A further 500 ml are given more slowly, taking 30–45 minutes. In severe haemorrhage 1,000 ml are infused as rapidly as possible. A further 500 ml may be given more slowly, depending on the clinical condition of the patient and the availability of cross-matched blood.

Crush injuries: The loss of plasma proteins into injured tissues and the consequent attraction of water out of the circulation may be combated by the infusion of 500–1,500 ml of Dextraven 110 or Dextraven 150. The rate of infusion is dictated by the degree of shock. Where this is severe, rapid infusion is necessary.

Burns: As a guiding principle up to 3,000 ml of Dextraven 110 or Dextraven 150 may be given in the first 36–48 hours. Electrolytes, dextrose and possibly blood will also be required according to the clinical situation.

Prophylaxis: Prior to major surgery a Dextraven 110 or Dextraven 150 drip at the rate of 10–20 drops a minute is set up as soon as the patient is anaesthetised. The drip rate may be adjusted to maintain the blood pressure during the operation. It is seldom necessary to continue the infusion after the operation is complete.

Contra-indications, warnings, etc *Anaphylactoid reactions* occur rarely. They are more common and may be more severe in patients with a history of asthma.

The most frequently observed signs of such reactions are hypotension and bronchospasm, progressing on very rare occasions to cardiac arrest. In addition, skin manifestations such as erythema and urticaria may be seen.

In view of the above it is essential to observe patients closely throughout the infusion, particularly during the first few minutes. If there is any suspicion of an anaphylactoid reaction, treatment with Dextraven should be discontinued immediately and appropriate resuscitative measures instituted.

In continuing haemorrhage, whole blood or packed cells may be indicated after 1,000–1,500 ml of Dextraven 110 or Dextraven 150 have been infused. This prevents over-dilution of clotting factors and maintains oxygen-carrying capacity. Where clotting factors are already

reduced (e.g. in hypofibrinogenaemia or thrombocytopenia) correction of this condition must be undertaken prior to or concomitantly with the Dextraven infusion.

Pharmaceutical precautions Do not store in excess of 25°C or expose to undue fluctuations in temperature. Do not use if cloudy or if a deposit is present. Discard any unused solution.

Legal category POM.

Package quantities Bottles of 500 ml.

Further information If blood samples are required for grouping and cross-matching, they should be taken when possible before infusion.

DIMYRIL* LINCTUS

Presentation Faintly opalescent, red liquid, each 5 ml of which contains 40 mg isoaminile citrate.

Uses For the treatment of cough associated with acute and chronic bronchitis, influenza, common cold, laryngitis and measles.

Dosage and administration *Oral: Adults:* 5 ml three to five times per day.

Children: 2.5–5 ml three to five times per day.

Infants: As recommended by the physician.

Contra-indications, warnings, etc *Side-effects:* Dizziness, nausea and constipation occur rarely.

Overdosage: Symptoms: Hallucinations and mania. Treatment: Withdrawal of drug; induction of vomiting/gastric lavage if large quantities taken; medical observation and supportive measures as necessary.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Bottle of 150 ml.

Further information Nil.

Product licence number 0113/5012.

FRAMYCORT* EYE AND EAR DROPS

Presentation Clear, very pale fawn coloured supernatant fluid with a fine white deposit which readily disperses on shaking. Contains:

Framycetin Sulphate BP	0.5% w/v
Hydrocortisone Acetate BP	0.5% w/v

Uses Treatment of superficial bacterial eye infections, conjunctivitis, blepharitis, marginal corneal ulceration and otitis externa.

Dosage and administration Direct application to the eye or into the auditory canal, 1–4 drops three to four times daily, or as directed by the physician.

Contra-indications, warnings, etc

Contra-indications: Viral infections. Known hypersensitivity to framycetin or benzalkonium chloride.

Precautions: In pregnant animals, administration of

Fisons plc
Pharmaceutical Division
12 Derby Road
Loughborough, Leics LE11 0BB

FISONS
Pharmaceuticals

ACNIL*

Presentation A smooth, soft, brownish-pink cream containing:

Precipitated Sulphur BP	3.0% w/w
Resorcinol BP	0.5% w/w
Cetrimide BP	0.5% w/w

Uses Acnil is a mild antiseptic and keratolytic for the treatment of acne vulgaris.

Dosage and administration *Adults:* Spread sparingly over the affected area only, twice daily until the spots disappear.

Children: At the discretion of the physician.

Contra-indications, warnings, etc

Contra-indication: Rosacea.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Tube of 25 g.

Further information Nil.

Product licence number 0113/5000.

AURALGICIN*

Presentation A pale yellow, viscous liquid containing:

Benzocaine BP	1.4% w/v
Ephedrine Hydrochloride BP	1.0% w/v
Phenazone BPC	5.5% w/v
Chlorbutol BP	1.0% w/v
Potassium Hydroxyquinoline Sulphate BPC	0.1% w/v
Glycerol BP	to 100%

Uses Antibacterial, analgesic ear drops for the treatment of acute and subacute otitis media.

Dosage and administration *Adults and children:*

1. The patient should be lying on his side – affected ear uppermost.
2. Pour the ear drops from the bottle into the affected ear until the ear is filled. (The patient will find it more soothing if the ear drops are warmed before placing them in the ear. This can be achieved by placing a teaspoon in warm water and then pouring the drops onto the dried warm spoon. The drops can now be applied to the ear from the spoon.)
3. Wait a few minutes before placing a plug of cotton wool into the ear.
4. Repeat the treatment hourly until no further pain is felt.
5. Thereafter the treatment should be repeated three-hourly for a period of 24 hours or until the doctor advises that no further treatment is necessary.

Note: If pain and inflammation persist after 24 hours the doctor should be consulted again.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to benzocaine or other ingredients. Not recommended for use in patients with perforated ear drums.

Pharmaceutical precautions *Important:* Replace the cap immediately after use. Do not use if cloudy as the effectiveness will be reduced.

For external use only.

Legal category P.

Package quantities Bottle of 12 ml.

Further information Appropriate systemic therapy may also be required.

Product licence number 0113/5003.

BARQUINOL* HC

Presentation Smooth, buff cream containing:

Hydrocortisone Acetate BP	0.5% w/w
Clioquinol BP	3.0% w/w

Uses Infective eczema, fungal infections, seborrhoeic dermatitis and pruritis.

Dosage and administration Apply directly to the affected area as a smear or as a spread on a dressing. Apply two or three times daily.

Contra-indications, warnings, etc *Precautions:* In pregnant animals, administration of corticosteroids can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for long periods.

In infants, long-term continuous topical therapy should be avoided. Adrenal suppression can occur even without occlusion.

Side-effects: Clioquinol may occasionally cause severe irritation.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Tube of 15 g.

Further information Nil.

Product licence number 0113/5004.

DEXTRAVEN* 110 IN DEXTROSE

DEXTRAVEN* 110 IN SALINE

DEXTRAVEN* 150 6% IN DEXTROSE

DEXTRAVEN* 150 6% IN SALINE

Presentation *Dextraven 110 in Dextrose:* a clear almost colourless slightly viscous liquid. *Dextran 110*

oses are required, 3–4 capsules may be given over 24 ours.

Contra-indications, warnings, etc Tetracyclines re selectively absorbed by developing bones and teeth nd may cause dental staining and enamel hypoplasia. r addition, these compounds readily cross the placental rrier and therefore Tetralysal 300 should not be dministered to pregnant women or children below the ge of 8 years unless in the opinion of the physician no ther less toxic agents are available.

As lymecycline is mainly excreted by the kidneys, it hould not be administered to patients with renal ufficiency.

Its use is also contra-indicated in patients sensitive to tetracyclines.

The absorption of tetracyclines may be affected by the imultaneous administration of milk, antacids and iron reparations.

It should also be borne in mind that the prolonged use f broad spectrum antibiotics may result in the appear- nce of resistant organisms and superinfection.

Overdosage: There is no specific treatment, but gastric vage should be performed as soon as possible. upportive measures should be instituted as required, nd a high fluid intake maintained.

Pharmaceutical precautions The capsules should be stored in air-tight containers in a cool place protected from light.

Legal category POM.

Package quantities Tetralysal 300 is available in bottles of 100 capsules.

Further information The active constituent of Tetralysal 300 is lymecycline, tetracycline chemically bonded to the amino acid L-lysine. It has been estimated that Tetralysal 300 (lymecycline 408 mg) is equivalent in its action to 500 mg of tetracycline hydrochloride.

Lymecycline is approximately 5,000 times more soluble than tetracycline base, and unlike tetracycline hydrochloride, it is soluble at all physiological pH values. (A 5% aqueous solution does not precipitate in the presence of serum.)

Product licence number Tetralysal 3433/0044.

**Trade Mark*

other intra-abdominal and intrapelvic infections; gonorrhoea; female genital tract infections; septicaemia; urinary tract infections; respiratory tract infections; bone and joint infections; skin and soft-tissue infections.

Mefoxin is also indicated for adjunctive therapy in the surgical treatment of infections, including abscesses, infection complicating hollow visceral perforations, cutaneous infections, and infections of serous surfaces, whether caused by aerobes, mixed aerobes and anaerobes, or anaerobes.

Clinical experience has demonstrated that Mefoxin can be administered to patients who are receiving carbenicillin, kanamycin, gentamicin, tobramycin, or amikacin.

Prevention: Mefoxin is indicated for the prevention of certain post-operative infections in patients undergoing contaminated or potentially contaminated surgical procedures or where the occurrence of post-operative infection could be serious.

Microbiology: Mefoxin is active in vitro against: Aerobic bacteria: *Gram-positive cocci* including: *Staphylococci*: (including coagulase-positive, coagulase-negative, and penicillinase-producing strains); Group A beta-haemolytic streptococci (*Streptococcus pyogenes*); Group B beta-haemolytic streptococci (*Streptococcus agalactiae*); *Streptococcus pneumoniae* (*Diplococcus pneumoniae*); other streptococci (except group D streptococci including enterococci, most strains of which are resistant, e.g. *Streptococcus faecalis*), *Gram-negative cocci* including: *Neisseria gonorrhoeae* (including penicillinase-producing strains); *Neisseria meningitidis*. *Gram-negative rods (facultative anaerobes)* including: *Escherichia coli*; *Klebsiella pneumoniae*; *Klebsiella spp.*; *Proteus mirabilis*. *Proteus* (indole-positive): *Proteus vulgaris*; *Proteus rettgeri*; *Proteus morganii*; *Haemophilus influenzae*; *Serratia marcescens*; *Providencia spp.*; *Salmonella* and *Shigella spp.*

Anaerobic bacteria: *Gram-positive cocci* including: *Peptococcus spp.*; *Peptostreptococcus spp.*; Microaerophilic streptococcus. *Gram-positive rods* including: *Clostridium perfringens*; *Clostridium spp.*; *Eubacterium spp.*; *Propionibacterium acnes*. *Gram-negative cocci* including: *Veillonella spp.* *Gram-negative rods* including: *Bacteroides fragilis*; *Bacteroides melaninogenicus*; *Bacteroides spp.* (including both penicillin-susceptible and penicillin-resistant strains); *Fusobacterium spp.*

Mefoxin is active against some strains of the following bacteria: *Acinetobacter calcoaceticus* var. *anitratum* (*Herellea vagincola*); *Acinetobacter calcoaceticus* var. *Iwoffi* (*Mima polymorpha*); *Alcaligenes faecalis*; *Citrobacter spp.* and *Flavo-bacterium spp.*; *Enterobacter spp.*

Mefoxin is not active against *Pseudomonas spp.*, most strains of enterococci, many strains of *Enterobacter cloacae*, and methicillin-resistant staphylococci.

Human pharmacology: Mefoxin administered parenterally, produces high serum and urine concentrations. It is excreted virtually unchanged as active Mefoxin by the kidneys, and has a mean terminal serum half-life of approximately one hour. Mefoxin passes rapidly into body fluids such as pleural, bile, and ascitic fluids. Probenecid slows tubular excretion and increases and prolongs blood levels.

Intravenous: Peak serum concentration of Mefoxin following 1 g infused intravenously over three minutes was 125 mcg/ml, infused over 30 minutes was 72 mcg/ml, and infused over 120 minutes was 25 mcg/ml. Following 2 g infused intravenously over

three minutes, peak serum concentration was 221 mcg/ml.

In a number of studies using 0.5 g, 1 g, or 2 g intravenous doses of Mefoxin mean total urinary recovery ranged from 77% to 99% of the cefoxitin dose.

Intramuscular: When Mefoxin was reconstituted for intramuscular injection with 0.5% or 1% lignocaine hydrochloride, the lignocaine had no effect on the absorption or elimination of Mefoxin.

Intramuscular injections of 1 g of Mefoxin in 0.5% lignocaine hydrochloride solution produced a peak serum concentration of 30 mcg/ml at 20 minutes. Approximately 85% of an intramuscular dose is excreted by the kidneys in the first six hours; this results in high urine levels (e.g. >3,000 mcg/ml between one and two hours after a 1 g dose).

Dosage and administration Mefoxin may be administered intravenously or intramuscularly. (See reconstitution directions for each route below.) Dosage and route of administration should be determined by severity of infection, susceptibility of the causative organisms, and condition of the patient.

Therapy may be started while awaiting the results of susceptibility testing.

Adults: Dosage: The usual adult dosage is 1 g or 2 g of Mefoxin every eight hours. (See 'Usual adult dosage' chart.)

In adults with renal insufficiency, an initial loading dose of 1 g to 2 g may be given. After a loading dose, the following recommendations for maintenance dosage may be used as a guide.

In the patients undergoing haemodialysis, the loading dose of 1–2 g should be given after each haemodialysis, and the maintenance dose should be given as indicated in the chart giving 'Maintenance dosage of Mefoxin in adults with reduced renal function'.

Children: Children three months of age and older: the recommended dosage in children of three months of age and older is 80–160 mg/kg of body weight per day divided into 4–6 equal doses. The total daily dosage may be increased to 200 mg/kg but not to exceed 12 g per day for severe infections.

No recommendation is made for children under three months of age.

In children with renal insufficiency dosage frequency should be reduced as indicated for adults.

Uncomplicated urinary tract infections: In uncomplicated urinary tract infections due to susceptible organisms, 1 g intramuscularly twice a day has been shown to be effective.

Uncomplicated gonorrhoea: For single dose therapy of uncomplicated gonorrhoea, including that caused by penicillinase-producing strains, the recommended dose is 2 g of Mefoxin intramuscularly given with 1 g of probenecid by mouth (at the same time or up to one hour before).

Prophylactic administration for adults: 2 g intramuscularly or intravenously just prior to surgery (approximately $\frac{1}{2}$ –1 hour before incision), then 2 g every 6 hours. Prophylactic therapy does not usually continue for more than 24 hours.

Prophylactic administration for children (3 months of age and older): 30–40 mg/kg at the times given for adults.

Caesarean section: 2.0 g intravenously as soon as the umbilical cord is clamped; and 2.0 g intravenously or intramuscularly 4 and 8 hours after the initial dose.

Subsequent doses may be given every six hours with usually no need to continue for more than 24 hours.

Intravenous administration: Reconstitute Mefoxin with Water for Injections BP: 1 g is soluble in 2 ml. Although Mefoxin is very soluble, for intravenous use it is preferable to add 10 ml of Water for Injections BP to the 1 g vial or to the 2 g vial. Shake to dissolve and then withdraw entire contents of vial into syringe.

Solutions of Mefoxin range from clear to light amber in colour. The pH of freshly reconstituted solutions usually ranges from 4.2 to 7.0.

For direct intravenous injection, Mefoxin may be slowly injected into the vein over a period of three to five minutes or may be given through the tubing when the patient is receiving parenteral solutions.

An intermittent intravenous infusion of Mefoxin may be employed when large amounts of fluid are to be given. However, during infusion of the solution containing Mefoxin, it may be advisable temporarily to discontinue administration of any other infusion solution at the same site (by using an appropriate IV infusion set).

A solution of Mefoxin may also be given by continuous intravenous infusion (see overleaf for compatibility and stability).

Intramuscular administration ONLY: Reconstitute Mefoxin 1 g with 2 ml of Water for Injections BP, or 0.5% or 1% lignocaine hydrochloride (without adrenaline) solution. Mefoxin is given by deep injection into a large muscle mass. Avoid injection into a blood vessel.

Note: Some patients may be hypersensitive to lignocaine.

Preparation of solution: The following table is provided for convenience in reconstituting Mefoxin for both intravenous and intramuscular administration.

Strength	Amount of diluent to be added (ml*)	Approximate average concentration (mg/ml)
1 gram vial	2 (Intramuscular)	400
1 gram vial	10 (IV)	95
2 gram vial	10 or 20 (IV)	180 or 95

* Shake to dissolve and let stand until clear.

Compatibility and stability: A solution of Mefoxin in Water for Injections BP may be added to the following solutions: 0.9% Sodium Chloride Injection BP, 5% or 10% Dextrose Injection BP, Dextrose and Sodium Chloride Injection BP (5%/0.9%, 5%/0.45%, or 5%/0.2%), Lactated Ringer's Injection USP, 5% Dextrose Injection in 0.02% sodium bicarbonate solution, 5% Dextrose in Lactated Ringer's Injection, 5% or 10% invert sugar in water, 10% invert sugar in saline solution, 4.2% Sodium Bicarbonate Injection BP, M/6 Sodium Lactate Injection BP, insulin (in normal saline or 10% invert sugar), heparin (100 units/ml and 0.1 units/ml), mannitol (2.5%, 5% and 10%).

Mefoxin has been shown to be chemically and visually compatible with aminoglycosides such as amikacin, gentamicin, kanamycin, and tobramycin mixed in 200 ml of 0.9% sodium chloride or 5% dextrose in water.

Contra-indications, warnings, etc

Contra-indications: Mefoxin is contra-indicated in persons who have shown hypersensitivity to cefoxitin. In the absence of clinical experience, Mefoxin should not be administered to patients who have shown hypersensitivity to cephalosporins.

Usual adult dosage

Type of infection	Dose (g)	Frequency (hrs)	Total daily dosage
Uncomplicated	1	Every 8 (occasionally every 6)	3 g (4 g)
Moderately severe or severe	2	Every 8 (occasionally every 6)	6 g (8 g)
Infections generally needing antibiotics in higher dosage	3 (2)	Every 6 (every 4)	12 g

Maintenance dosage of Mefoxin in adults with reduced renal function

Renal function	Creatinine clearance (ml/min)	Dose (g)	Frequency (hrs)
Mild impairment	50-30	1-2	Every 8-12
Moderate impairment	29-10	1-2	Every 12-24
Severe impairment	9-5	0.5-1	Every 12-24
Essentially no function	<5	0.5-1	Every 24-48

Precautions: There is some clinical and laboratory evidence of partial cross-allergenicity between cephamycins and other beta-lactam antibiotics, penicillins, and cephalosporins. Severe reactions (including anaphylaxis) have been reported with most beta-lactam antibiotics.

Before therapy with Mefoxin, careful inquiry should be made concerning previous hypersensitivity reactions to beta-lactam antibiotics. Mefoxin should be given cautiously to penicillin-allergic patients.

Any patient who has demonstrated some form of allergy, particularly to drugs, should receive antibiotics cautiously. If an allergic reaction to Mefoxin occurs, the drug should be discontinued.

The total daily dosage should be reduced when Mefoxin is administered to patients with transient or persistent reduction of urinary output due to renal insufficiency because high and prolonged serum antibiotic concentrations can occur from usual dosages.

Interference with laboratory tests: A false-positive reaction to glucose in the urine may occur with reducing substances but not with the use of specific glucose oxidase methods.

Using the Jaffe technique, falsely high creatinine values in serum may occur if Mefoxin serum concentrations exceed 100 mcg/ml. Serum samples from patients treated with Mefoxin should not be analysed for creatinine if withdrawn within two hours of drug administration.

Use in pregnancy: Use of the drug in women of childbearing potential requires that the anticipated benefits be weighed against possible hazards. Reproductive and teratogenic studies have been performed in mice and rats and have revealed no evidence of impaired fertility or harm to the foetus due to Mefoxin. There are no controlled studies with Mefoxin in pregnant women.

Nursing mothers: Mefoxin is excreted in human milk.

Infants under three months of age: Clinical trials are proceeding in infants under three months of age. Pending the outcome of these trials, dosage recommendations for such infants remain to be established.

Side-effects: Mefoxin is generally well tolerated. Side-effects rarely require stopping treatment and usually have been mild and transient.

Local reactions: Thrombophlebitis has occurred with intravenous administration. Pain, induration and tenderness after intramuscular injections have been reported.

Allergic: Maculopapular rash, urticaria, pruritus, eosinophilia, fever and other allergic reactions have been noted rarely.

Gastro-intestinal: Nausea, vomiting, and diarrhoea have been reported rarely.

Blood: Transient leucopenia, neutropenia and haemolytic anaemia have been reported. Some individuals, particularly those with azotaemia, may develop positive direct Coombs tests during therapy with Mefoxin.

Liver function: Transient elevations in SGOT, SGPT, serum LDH, and serum alkaline phosphatase have been reported rarely.

Kidney: Elevations in serum creatinine and/or blood urea levels have been observed. The role of Mefoxin in changes in renal function tests is difficult to assess, since factors predisposing to pre-renal azotaemia or to impaired renal function usually have been present.

Treatment of overdosage: No information is available at present.

Pharmaceutical precautions Mefoxin, as reconstituted with Water for Injections BP, Water for Injections BP preserved with parabens or benzyl alcohol, 0.9% Sodium Chloride Injection BP, 5% Dextrose Injection BP, or 0.5% and 1.0% lignocaine hydrochloride (preserved in parabens), maintains satisfactory potency for 24 hours at room temperature, for one week under refrigeration (below 5°C) and for at least 30 weeks in the frozen state and will maintain potency after thawing for at least 24 hours at room temperature.

After reconstitution with Water for Injections BP and subsequent storage in disposable plastic syringes, Mefoxin is stable for 24 hours at room temperature and 48 hours under refrigeration.

After the periods mentioned above, any unused solutions or frozen material should be discarded. Do not refreeze.

Note: Mefoxin in the dry state should be stored below 30°C. Avoid exposure to temperatures above 50°C. The dry material as well as solutions tend to darken, depending on storage conditions; product potency, however, is not adversely affected.

Legal category POM.

Package quantities Sterile Mefoxin is supplied in vials containing 1 g or 2 g of cefoxitin as the sodium salt.

Further information Nil.

2 g 0025/0131

MINTEZOL*

Presentation Orange-coloured chewable tablets,

marked 'MSD 907', containing 500 mg Thiabendazole BPC.

Uses Anthelmintic.

For the following intestinal helminthiases (singly or in combination): enterobiasis (threadworm disease), strongyloidiasis, ascariasis (large roundworm disease), uncinariasis (hookworm disease – *Necator americanus*, *Ancylostoma braziliense*, and *Ancylostoma duodenale*), trichuriasis (whipworm disease), Dracunculiasis (guinea worm).

Mintezol kills adult worms, and also the eggs of threadworm (*Enterobius vermicularis*, sometimes called pinworm), roundworm, and hookworm. It interferes with the embryonation and larval stage development of strongyloides. The anthelmintic activity against whipworm (*Trichuris trichiura*) is not predictable.

Mintezol is also indicated in cutaneous larva migrans (creeping eruption). In trichinosis, Mintezol can relieve symptoms and fever and reduce eosinophilia during the invasion stage, but its effect on the larvae of *Trichinella spiralis* which have migrated to muscle is questionable.

Dosage and administration Dosage depends on the body weight of the patient and is independent of the condition being treated. Usually, 2 doses are given each day. For patients weighing less than 60 kg (132 lb), each dose is based on 25 mg thiabendazole per kg body weight. For patients weighing 60 kg or more, each dose is 1.5 g thiabendazole. The maximum daily dosage for adults weighing 60 kg or more is 3 g.

Mintezol should be taken with meals. Dietary restrictions, complementary medications and cleansing enemas are not necessary.

The table below relates dosage to body weight:

Duration of therapy does depend on the particular nematode infestation, and is as follows:

Enterobiasis: 2 doses on one day, repeated a week later. This regime is intended to reduce the risk of reinfection due to viable eggs in the environment. If this is not practicable, the patient can be given 2 doses a day for two successive days.

Patient's weight		Dose (twice daily)
kg	lb	Tablets (500 mg thiabendazole)
10	22	$\frac{1}{2}$
20	44	1
30	66	1½
40	88	2
50	110	2½
60	132 (or more)	3

Strongyloidiasis, ascariasis, uncinariasis and trichuriasis: 2 doses a day for two successive days. Alternatively, a single dose of 50 mg/kg may be given, but a high incidence of side-effects would be expected.

(Clinical experience with thiabendazole in the treatment of the conditions in the above paragraph in children weighing less than 15 kg has been limited.)

Cutaneous larva migrans: 2 doses a day for two successive days. If active lesions are still present two days after completion of this therapy, a second similar course is recommended.

Trichinosis: 2 doses a day for two to four successive days, according to the response of the patient. The

optimum dosage in trichinosis has not yet been established. (Clinical experience with thiabendazole in the treatment of this condition in children weighing less than 15 kg has been limited.)

Dracunculiasis: 50–100 mg/kg in two equally divided doses for one day. The lower dosage for patients with 1 or 2 visible worms; the higher dosage for patients with multiple infection (3 or more worms). In massive infections (10 worms or more), 50 mg/kg can be given five to eight days after treatment, if required.

Further considerations: In certain patients, 2 doses a day may lead to a higher incidence of side-effects. In these circumstances, 25 mg per kg body weight may be given after the largest meal on the first day and repeated 24 hours later after a similar meal on the second day.

For mass treatment, a single dose of 50 mg/kg after the evening meal is highly effective and most convenient, though a higher incidence of side-effects may be expected.

Contra-indications, warnings, etc

Contra-indications: A history of hypersensitivity to thiabendazole.

Precautions: If any hypersensitivity reactions occur, therapy should be discontinued immediately and not resumed. Erythema multiforme, including a fatal case of Stevens-Johnson syndrome, has been associated with thiabendazole therapy in children.

Mintezol may impair alertness in some patients, who should avoid driving, operating machinery, or other activities made hazardous by diminished alertness.

Ideally, anaemic, dehydrated or malnourished patients should be given supportive therapy before starting treatment with Mintezol. Liver and renal function should be carefully monitored in patients with disorders of these organs.

Use in pregnancy and lactation: Clinical experience and follow-up studies of the effect of thiabendazole in pregnancy and lactation have been limited. The use of Mintezol in these conditions requires that the potential benefits should be weighed against possible hazards to mother or child. It is excreted in the milk of cattle. Reproduction studies of successive generations of mice, rats, pigs, rabbits, cattle and sheep have shown no foetal abnormalities which could be directly attributable to thiabendazole.

Side-effects: The most common are anorexia, nausea, vomiting and dizziness. Diarrhoea, epigastric distress, pruritus, weariness, giddiness, headache and drowsiness occur less often.

Fever, facial flushing, chills, conjunctival injection, angioneurotic oedema, anaphylaxis, lymphadenopathy, erythema multiforme including Stevens-Johnson syndrome, peri-anal rash and skin rash have occurred infrequently; whether these represent hypersensitivity to thiabendazole, to the parasite, or a manifestation of the disease, is uncertain.

Rare side-effects are tinnitus, collapse, abnormal sensation in the eyes, blurring of vision, hyperirritability, numbness, hyperglycaemia, yellow vision, enuresis, hypotension, cholestasis and parenchymal liver damage, and a transitory rise in cephalin flocculation and SGOT. The appearance of live ascaris in the mouth and nose has been reported on rare occasions.

Some patients excrete a metabolite which imparts a characteristic odour to their urine, similar to that which occurs after eating asparagus. This odour lasts for about

one day after therapy is completed. Crystalluria, with and without haematuria, has been reported, but it promptly subsided when therapy was stopped. A few patients on Mintezol have developed transient leucopenia, but a cause and effect relationship has not been established.

Treatment of overdose: Symptomatic and supportive: there is no specific antidote. The stomach should be emptied by emesis or gastric lavage.

Pharmaceutical precautions Keep container tightly closed; store in a cool place, protect from light.

Legal category P.

Package quantities *Tablets:* Packs of 6.

Further information Mintezol should always be taken after a full meal.

Product licence number 0025/5031.

MODURETIC*

Presentation Peach-coloured, half-scored, diamond-shaped tablets, marked 'MSD 917', containing 5 mg amiloride hydrochloride and 50 mg Hydrochlorothiazide BP.

Aniseed/peppermint-flavoured solution containing 5 mg amiloride hydrochloride and 50 mg hydrochlorothiazide BP in each 5 ml.

Uses Potassium-conserving diuretic and anti-hypertensive.

For the treatment of patients with hypertension, congestive heart failure, or hepatic cirrhosis with ascites, in whom potassium depletion might be anticipated. The presence of amiloride hydrochloride in Moduretic minimises the likelihood of excessive potassium loss during vigorous diuresis for long-term therapy. Moduretic is particularly indicated in conditions where potassium balance is especially important, e.g. patients with congestive heart failure receiving digitalis.

In hepatic cirrhosis with ascites, Moduretic usually provides satisfactory diuresis with diminished potassium loss and less risk of metabolic alkalosis.

Dosage and administration The rate of loss of weight and the serum electrolyte levels should determine the dosage. The most satisfactory rate of weight loss after initiation of diuresis is about 0.5–1.0 kg/day.

Moduretic is not recommended for children.

Hypertension: Usually 1 or 2 tablets (or 1 or 2 teaspoonfuls, 5 or 10 ml) once-a-day or in divided doses. The dosage may be increased if necessary, but not exceeding 4 tablets (or 4 teaspoonfuls) a day.

Moduretic may be used alone or as an adjunct to other antihypertensive drugs such as Aldomet* (methyldopa, MSD) or Blocadren* (timolol maleate, MSD). Since Moduretic enhances the action of these agents, the dosage of the antihypertensive drugs may have to be reduced to avoid an excessive drop in blood pressure.

Studies have shown that Blocadren and Moduretic can be used together once daily. The majority of patients will respond to 10–20 mg Blocadren once daily and 1 tablet (or 1 teaspoonful) of Moduretic.

Congestive heart failure: Initially 1 or 2 tablets (or 1 or 2 teaspoonfuls) a day, subsequently adjusted if required, but not exceeding 4 tablets (or 4 teaspoonfuls) a day. Optimal dosage is determined by the diuretic response

and the serum potassium level. Once an initial diuresis has been achieved, reduction in dosage may be attempted for maintenance therapy. Maintenance therapy may be on an intermittent basis.

Hepatic cirrhosis with ascites: Initially 1 tablet (or 1 teaspoonful) a day, increased gradually if necessary until there is effective diuresis, but not exceeding 4 tablets (or 4 teaspoonfuls) a day. A gradual weight reduction is especially desirable in cirrhotic patients, to reduce the likelihood of untoward reactions associated with diuretic therapy. Maintenance dosage may be lower than those required to initiate diuresis; dosage reduction should therefore be attempted when the patient's weight is stabilised.

Contra-indications, warnings, etc

Contra-indications: Hyperkalaemia (serum potassium over 5.5 mEq/litre); other potassium-conserving diuretics, and potassium supplements; anuria; acute renal failure, severe progressive renal disease, diabetic nephropathy; patients with blood urea over 60 mg per 100 ml or serum creatinine over 1.5 mg per 100 ml, in whom serum electrolyte and blood urea levels cannot be monitored carefully and frequently; prior sensitivity to amiloride hydrochloride or hydrochlorothiazide. In renal impairment, use of potassium-conserving agent may result in rapid development of hyperkalaemia. The safety of amiloride hydrochloride for use in children has not been established; Moduretic is therefore not recommended in children. For 'Use in pregnancy and the nursing mother', see 'Precautions'.

Precautions: **Diabetes mellitus:** Hyperkalaemia has commonly occurred in diabetic patients on amiloride hydrochloride, especially those with chronic renal disease or pre-renal azotaemia. The status of renal function should therefore be determined before Moduretic is given to known or suspected diabetics.

Moduretic should be discontinued before giving a glucose-tolerance test, as one patient with poorly controlled diabetes mellitus, who became severely hyperkalaemic while receiving amiloride hydrochloride, died following two repeated intravenous glucose-tolerance tests. The insulin requirements of diabetic patients may need to be changed. Diabetes mellitus which has been latent may become manifest during thiazide administration.

Metabolic or respiratory acidosis: Potassium-conserving therapy should be initiated only with caution in severely ill patients in whom metabolic or respiratory acidosis may occur, e.g. patients with cardiopulmonary disease or decompensated diabetes. Shifts in acid-base balance alter the balance of extracellular/intracellular potassium, and the development of acidosis may be associated with rapid increases in serum potassium.

Hyperkalaemia (serum potassium level over 5.5 mEq/litre): This has been observed in patients receiving amiloride hydrochloride, either alone or with other diuretics, particularly in the aged, in diabetics, and in hospital patients with hepatic cirrhosis or congestive heart failure who had known renal involvement, were seriously ill, or were undergoing vigorous diuretic therapy. Such patients should be carefully observed for clinical, laboratory and ECG evidence of hyperkalaemia (not always associated with an abnormal ECG). Some deaths have been reported in this group of patients. Should hyperkalaemia develop, Moduretic should be discontinued immediately, and if necessary, active measures taken to reduce the serum potassium to normal.

Electrolyte imbalance and blood urea increases: Hypo-natraemia and hypochloreaemia may occur, although the likelihood of hypochloreaemic alkalosis is reduced with Moduretic. Any chloride deficit may be corrected by the use of ammonium chloride (except in patients with liver disease), and largely prevented by a near-normal salt intake.

Reversible increases in blood urea have been reported accompanying vigorous diuresis, especially in seriously ill patients, such as those with hepatic cirrhosis with ascites and metabolic alkalosis or those with resistant oedema; serum electrolyte and blood urea levels should be carefully monitored in these patients.

Moduretic should be used with caution in patients with renal impairment. Special care should be taken to avoid cumulative or toxic effects due to a reduced excretion of its components. In addition, azotaemia may be precipitated or increased by hydrochlorothiazide. If increasing azotaemia and oliguria occur during treatment, Moduretic should be discontinued.

Effects in cirrhotic patients: Oral diuretic therapy is more frequently accompanied by adverse reactions in patients with hepatic cirrhosis and ascites because these patients are intolerant of acute shifts in electrolyte balance, and because they often have pre-existing hypokalaemia as a result of associated aldosteronism. Hepatic encephalopathy, manifested by tremors, confusion and coma, has been reported in patients on amiloride hydrochloride. Patients with liver disease should be observed for this complication when Moduretic is given. In cirrhotic patients receiving amiloride hydrochloride alone, a deepening of jaundice has occurred, but the relationship to amiloride is uncertain.

Other precautions: Sensitivity reactions to thiazides may occur in patients with or without a history of allergy or bronchial asthma. Hydrochlorothiazide potentiates the action of other antihypertensive agents. Therefore the dosage of these agents, especially the ganglionic blockers, may need to be reduced when Moduretic is added to the regimen. Lithium should generally not be given to patients receiving diuretics, since the risk of lithium toxicity is very high in such patients. The possibility that the thiazides may activate or exacerbate systemic lupus erythematosus has been reported.

Hydrochlorothiazide may decrease arterial responsiveness to noradrenaline, but not enough to prevent noradrenaline being effective in therapeutic usage. Thiazides may increase responsiveness to tubocurarine. The antihypertensive effect of thiazides may be enhanced in the post-sympathectomy patient. Orthostatic hypotension may occur, and may be potentiated by alcohol, barbiturates and narcotics.

Calcium excretion is decreased by hydrochlorothiazide and magnesium excretion is increased.

Thiazides may decrease serum PBI levels without signs of thyroid disturbance. Pathological changes in the parathyroid glands, accompanied by hypercalcaemia and hypophosphataemia, have been reported in a few patients receiving prolonged thiazide therapy. The common complications of hyperparathyroidism have not been observed. Thiazides should be discontinued before carrying out tests for parathyroid function.

Hyperuricaemia may occur, or gout may be precipitated, in certain patients receiving thiazides.

As with any drug, patients should be observed regularly for the possible occurrence of liver dysfunction, idiosyncratic reactions, or blood dyscrasias.

Use in pregnancy and the nursing mother: As clinical

experience is limited, Moduretic is not recommended for use during pregnancy. Thiazides appear in breast milk. If use of the drug is deemed essential, the patient should stop nursing. Since thiazides cross the placental barrier and appear in cord blood, the use of Moduretic where pregnancy is present or suspected requires that the benefits of the drug be weighed against possible hazards to the foetus. These hazards include foetal or neonatal jaundice, thrombocytopenia, and possibly other side-effects that have occurred in the adult. The routine use of diuretics in otherwise healthy pregnant women with or without mild oedema is not indicated.

Side-effects: *Gastro-intestinal:* Anorexia, nausea, vomiting, abdominal fullness, gastric irritation, cramps, pain, constipation and diarrhoea. Studies performed in normal subjects have shown no significant effect of amiloride on gastric secretion.

Related to diuresis: Dry mouth, thirst, paraesthesiae, transient blurred vision, salivary gland inflammation, dizziness, vertigo, weakness, susceptibility to fatigue, muscle cramps, orthostatic hypotension.

Other side-effects: Reversible adverse reactions reported with Moduretic are skin rash, pruritus, and such minor psychiatric disturbances as confusion. Transient visual disturbances have also been noted.

Side-effects associated with thiazide therapy are headache, restlessness, jaundice (intrahepatic cholestatic jaundice), pancreatitis, yellow vision, hyperglycaemia, glycosuria, hyperuricaemia. Thrombocytopenia, leucopenia, agranulocytosis, aplastic anaemia, haemolytic anaemia, purpura, rash, urticaria, photosensitivity, necrotising angitis (vasculitis, cutaneous vasculitis), fever, respiratory distress including pneumonitis and anaphylactic reactions have also been reported.

There have been isolated instances of gastro-intestinal bleeding in patients with a history of gastro-intestinal disease receiving amiloride hydrochloride alone; a causal relationship to amiloride has not been established. Rare reversible abnormalities, thought to be related to amiloride hydrochloride, have been observed in liver function tests. One patient with pre-existing partial heart block developed complete heart block after receiving amiloride hydrochloride.

Whenever side-effects are moderate or severe, the dosage of Moduretic should be reduced, or therapy withdrawn.

Treatment of overdosage: Dehydration, electrolyte imbalance and hepatic coma are treated by the established procedures. There is no specific antidote. If ingestion is recent, emesis should be induced or gastric lavage performed. Treatment is symptomatic and supportive. If hyperkalaemia occurs, active measures should be taken to reduce the serum potassium levels. For respiratory impairment, oxygen or artificial respiration should be administered.

Pharmaceutical precautions Keep container tightly closed; store in a cool place, protected from light.

Legal category POM.

Package quantities

Bottles of 100 and 500 tablets.
Bottles of 200 ml solution.

Further information Oral potassium supplements must not be given with Moduretic.

Onset of diuretic action begins within two to four hours after administration of Moduretic, and reaches a

peak at about the fourth hour; there is detectable activity for about 24 hours.

Tablets 0025/5016
Solution 0025/0165

PERIACTIN*

Presentation White, half-scored tablets, marked 'MSD 62', containing Cyproheptadine Hydrochloride BP equivalent to 4 mg anhydrous cyproheptadine hydrochloride.

A yellow syrup containing, in each 5 ml, Cyproheptadine Hydrochloride BP equivalent to 2 mg anhydrous cyproheptadine hydrochloride.

Uses *As an appetite stimulant:* Periacetin is recommended for those patients with decreased appetite or poor eating habits with resulting underweight, where stimulation of appetite, with weight gain, is desirable.

In allergy and pruritus: Periacetin has a wide range of anti-allergic and antipruritic activity, and can be used successfully in treatment of acute and chronic allergic and pruritic conditions, such as: dermatitis, including neurodermatitis and neurodermatitis circumscripta; eczema; eczematoid dermatitis; dermatographism; mild, local allergic reactions to insect bites; hay fever and other seasonal rhinitis; perennial allergic and vasomotor rhinitis; allergic conjunctivitis due to inhalant allergies and foods; urticaria; angioneurotic oedema; drug and serum reactions; anogenital pruritus; pruritus of chickenpox.

Periacetin is indicated as adjunctive therapy to adrenaline and other standard measures for the relief of anaphylactic reactions after the acute manifestations have been controlled.

In migraine headache: Periacetin has been reported to have beneficial effects in a significant number of patients having vascular types of headache. Many patients who have responded inadequately to all other agents have reported amelioration of symptoms with Periacetin. The characteristic headache and feeling of malaise may disappear within an hour or two of the first dose.

Dosage and administration There is no recommended dosage for children under 2 years old. Periacetin is not recommended for elderly debilitated patients.

As an appetite stimulant: Daily dosage may be given as a single dose once a day in the evening or alternatively in divided doses. Dosage should be individualised according to the needs and response of the patient.

Adults and adolescents: The usual dosage appears to be 4 mg (1 tablet or two 5 ml spoonfuls) three times a day. Larger doses are neither required nor recommended for appetite stimulation.

Children aged 7-14 years: The dosage should not exceed 12 mg (3 tablets or six 5 ml spoonfuls) a day.

Children aged 2-6 years: The dosage should not exceed 8 mg (2 tablets or four 5 ml spoonfuls) a day.

The effect of Periacetin on appetite and weight gain only occurs during the period of its administration. After therapy is stopped, there may be some weight loss, but usually not to pre-treatment levels.

In allergy and pruritus: Dosage must be determined on an individual basis. The effect of a single dose usually lasts for four to six hours. For continuous effective relief,

the daily requirement should be given in divided doses, three or four times a day, or as often as necessary.

Adults: 4–20 mg a day, most patients requiring 12–16 mg a day.

Maximum: 32 mg a day.

Children aged 7–14 years: Usually 4 mg three times a day, according to the patient's weight and response. Any additional dosage should be given at bedtime. Maximum 16 mg a day.

Children aged 2–6 years: Initially 2 mg three times a day, adjusted according to the patient's weight and response. Any additional dosage should be given at bedtime. Maximum 12 mg a day.

In vascular headache and migraine: For both prophylactic and therapeutic use at an initial dose of 4 mg repeated if necessary after half an hour. Patients who respond usually obtain relief with 8 mg, and this dose should not be exceeded within a 4- to 6-hour period.

Maintenance: 4 mg every four to six hours.

Contra-indications, warnings, etc

Contra-indications: Concurrent use with monoamine oxidase inhibitors; glaucoma; predisposition to urinary retention; stenosed peptic ulcer; pyloroduodenal obstruction; symptomatic prostatic hypertrophy; bladder neck obstruction; during an acute asthmatic attack; elderly debilitated patients; nursing mothers; newborn or premature infants; known sensitivity to cyproheptadine hydrochloride.

Precautions: Antihistamines should not be used to treat lower respiratory tract symptoms including those of acute asthma. Alertness may be impaired in some patients. Driving a car or other activities made hazardous by diminished alertness should be avoided. Antihistamines are more likely to cause dizziness, sedation and hypotension in the elderly; and conversely, occasionally excitation in the young child. Patients receiving Periacin should be warned not to take alcohol or other CNS depressants. When Periacin is considered for patients who present with symptoms of severe loss of appetite, care should be taken to exclude and serious underlying pathology.

Rarely, prolonged therapy with antihistamines may cause blood dyscrasias.

The use of any drug in pregnancy or in women of child-bearing age requires that the potential benefits be weighed against its possible hazards to mother and child.

Drug interactions: MAO inhibitors prolong and intensify the anticholinergic effects of antihistamines.

Patients should be cautioned against taking alcohol and other central nervous system depressants.

Side-effects: The only side-effects that appear frequently are drowsiness and somnolence; many patients who initially complain of these may no longer do so after the first three or four days of continuous therapy. Drowsiness may be desirable in children by decreasing the emotional tension often associated with anorexia; and in patients with dermatitis and pruritus since it tends to increase the threshold of perception and reduce emotional tension. Dry mouth, dizziness, apprehensiveness, faintness, dryness of the mucous membranes, headache, nausea, and allergic manifestations of skin rash and oedema have been reported in low incidence. On rare occasions, CNS stimulation (as manifested by agitation, confusion, visual hallucinations) may occur. Other side-effects reported rarely are fatigue, excitation, disturbed co-ordination, tremor, irritability, insomnia, and vomiting. Also, photo-

sensitivity, epigastric distress, diarrhoea, palpitations, nervousness, restlessness, paraesthesiae, blurred vision, and thrombocytopenia.

Treatment of overdosage: Emesis should be induced or gastric lavage performed. A saline cathartic should be given and respiration maintained. Convulsive stimulants should be avoided. Generally, treatment is symptomatic and supportive.

Pharmaceutical precautions Periacin should be kept in a cool, dry place; the syrup should also be protected from freezing. Periacin Syrup may be diluted with Syrup BP; the mixture should be used within 14 days.

Legal category P.

Package quantities *Tablets:* Bottles of 100 and 500. *Syrup:* Bottles of 200 ml.

Further information Periacin is the first clinically proved appetite stimulant. At the recommended dosage, it increases the desire to eat in a high proportion of patients. Gain in weight usually results from the increased food intake, and is generally seen after the first week of therapy. There is no clinical evidence of fluid retention or disturbance of endocrine function.

Tablets 0025/5017
Syrup 0025/5018

SALURIC*

Presentation White, half-scored tablets, marked 'MSD 432', containing 500 mg Chlorothiazide BP.

Uses Thiazide diuretic.

Oedema associated with congestive heart failure, hepatic cirrhosis, premenstrual tension, drug-induced oedema, and in oedema due to various forms of renal dysfunction (i.e. nephrotic syndrome, acute glomerulonephritis and chronic renal failure). Hypertension, either alone or as an adjunct to other hypertensive drugs, such as Aldomet* (methyldopa, MSD) or Blocadren* (timolol maleate, MSD).

Dosage and administration *Adults – for oedema:* Usually 1 or 2 tablets (0.5–1.0 g) once or twice a day. Many patients respond to intermittent therapy: every other day, or three to five consecutive days a week. Intermittent therapy is less likely to produce excessive diuretic response with resulting electrolyte imbalance.

In oedema accompanying premenstrual tension: $\frac{1}{2}$ –1 tablet once or twice a day, from the first morning of symptoms until the onset of the menses.

Adults – for control of hypertension: Initially, usually 0.5 g or 1.0 g a day as a single or divided dose, increased or decreased according to response. Some patients may need 4 tablets (2.0 g) a day (in divided doses).

Thiazides may add to or potentiate the action of other antihypertensives. If Saluric is added to therapy with other antihypertensive agents, dosage reduction of such agents may be necessary to prevent an excessive drop in blood pressure.

Infants and children: Usually 25 mg per kg body weight a day, given in 2 doses. Infants under 6 months may need up to 35 mg per kg a day, in 2 doses.

On this basis, infants up to 2 years of age may be given

125–375 mg of Saluric daily in 2 doses. Children from 2 to 12 years of age may be given 375 mg to 1.0 g daily in 2 doses. Dosage in both age groups should be based on body weight.

Contra-indications, warnings, etc

Contra-indications: Anuria, known hypersensitivity to chlorothiazide. See also 'Use in pregnancy and the nursing mother', under 'Precautions'.

Precautions: Azotaemia may be precipitated or increased by Saluric. Cumulative effects of chlorothiazide may develop in patients with impaired renal function. If increasing azotaemia and oliguria occur during treatment of severe progressive renal disease, Saluric should be discontinued.

Thiazides should be used with caution in patients with impaired hepatic function or progressive liver disease, since minor alterations of fluid and electrolyte balance, or of serum ammonia, may precipitate hepatic coma.

Sensitivity reactions may occur in patients with or without a history of allergy or bronchial asthma.

Saluric adds to or potentiates the action of other antihypertensive agents. Potentiation occurs with ganglion- or adrenergic-blocking drugs.

The possibility of exacerbation or activation of systemic lupus erythematosus has been reported.

Patients should be carefully monitored for signs of fluid and electrolyte imbalance (hyponatraemia, hypomagnesaemia, hypochlorhaemic alkalosis and hypokalaemia). It is particularly important to make serum and urine electrolyte determinations when the patient is vomiting excessively or receiving parenteral fluids. Warning signs, irrespective of cause, are: dryness of mouth, thirst, weakness, lethargy, drowsiness, restlessness, muscle pains or cramps, muscular fatigue, hypotension, oliguria, tachycardia and gastro-intestinal disturbances.

Hypokalaemia may develop, especially with brisk diuresis, when severe cirrhosis is present, or during concurrent steroid or ACTH administration. Interference with adequate electrolyte intake will contribute to hypokalaemia. Hypokalaemia can sensitise or exaggerate the response of the heart to the toxic effects of digitalis (e.g. increased ventricular irritability).

Hypokalaemia may be avoided or treated in the adult by concurrent use of Midamor* (amiloride hydrochloride), a potassium-conserving agent. It also may be avoided by giving potassium chloride or foods with a high potassium content. (Note that symptoms and signs which might indicate ulceration or obstruction of the small bowel in patients taking tablets or capsules containing potassium salts are indications for stopping treatment with such preparations immediately.)

Any chloride deficit is generally mild and does not usually require specific treatment except under unusual circumstances (as in liver or renal disease). Dilutional hyponatraemia may occur in oedematous patients in hot weather; except in rare instances when hyponatraemia is life-threatening, appropriate therapy is water restriction rather than administration of salt. In actual salt depletion, appropriate replacement is the therapy of choice.

Thiazides may increase responsiveness to tubocurarine. The antihypertensive effect of the thiazide may be enhanced in the post-sympathectomy patient. Chlorothiazide may decrease arterial responsiveness to noradrenaline, but not enough to prevent noradrenaline being therapeutically useful. Orthostatic hypotension may occur, and may be potentiated by alcohol, barbiturates or narcotics.

Thiazides may decrease serum protein-bound iodine levels without signs of thyroid disturbances.

Saluric decreases calcium excretion.

Pathological changes in the parathyroid glands, with hypercalcaemia and hypophosphataemia, have been observed in a few patients on prolonged thiazide therapy. The common complications of hyperparathyroidism such as renal lithiasis, bone resorption and peptic ulceration have not been seen. Thiazides should be discontinued before carrying out tests for parathyroid function.

Hyperuricaemia may occur, or gout may be precipitated, in certain patients receiving thiazide therapy.

Insulin requirements in diabetic patients may be increased, decreased or unchanged. Latent diabetes mellitus may become manifest during thiazide administration.

Lithium should generally not be given to patients receiving diuretics, since the risk of lithium toxicity is very high in such patients.

Use in pregnancy and the nursing mother: Thiazides appear in breast milk. If use of the drug is deemed essential the patient should stop nursing. Thiazides cross the placental barrier and appear in the cord blood. Therefore, the use of Saluric, when pregnancy is present or suspected, requires that the benefits of the drug be weighed against the possible hazards to the foetus. These hazards include foetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. The routine use of diuretics in otherwise healthy, pregnant women with or without mild oedema is not indicated.

Side-effects: Gastro-intestinal system: Anorexia, gastric irritation, nausea, vomiting, cramps, diarrhoea, constipation, jaundice (intrahepatic cholestatic jaundice), pancreatitis, salivary gland inflammation.

Central nervous system: Dizziness, vertigo, paraesthesiae, headache, yellow vision.

Haematological: Leucopenia, agranulocytosis, thrombocytopenia, aplastic anaemia, haemolytic anaemia.

Cardiovascular: Orthostatic hypotension (may be aggravated by alcohol, barbiturates, narcotics).

Hypersensitivity: Purpura, photosensitivity, rash, urticaria, necrotising angitis (vasculitis, cutaneous vasculitis), fever, respiratory distress including pneumonitis, anaphylactic reactions.

Other: Hyperglycaemia, glycosuria, hyperuricaemia, muscle spasm, weakness, restlessness, transient blurred vision.

Whenever side-effects are moderate or severe, thiazide dosage should be reduced or therapy withdrawn.

Treatment of overdosage: Symptomatic and supportive; no specific antidote. If ingestion is recent the stomach should be emptied by emesis or gastric lavage. Dehydration, electrolyte imbalance, hepatic coma, and hypotension should be corrected by standard methods. For impaired respiration, oxygen or artificial respiration should be given.

Pharmaceutical precautions Keep container tightly closed; store in a cool place, protected from light.

Legal category POM.

Package quantities Bottles of 100 and 500.

Further information Diuresis usually begins within two hours, is at a peak after four hours and persists for six to twelve hours. No rigid dietary salt restriction required.

Product licence number 0025/5019.

SINEMET®

Presentation The standard strength is known as Sinemet-275 and is supplied as dapple-blue, half-scored, oval tablets, marked 'MSD 654', containing 25 mg carbidopa (as carbidopa monohydrate) and 250 mg Levodopa BP.

Sinemet-Plus is available as yellow, half-scored, oval tablets, marked 'SINEMET PLUS', containing 25 mg carbidopa (as carbidopa monohydrate) and 100 mg levodopa.

Sinemet-110 is available as dapple-blue, half-scored, oval tablets, marked 'MSD 647', containing 10 mg carbidopa (as carbidopa monohydrate) and 100 mg Levodopa BP.

Uses Antiparkinsonian agent.

For treatment of Parkinson's disease and syndrome. Sinemet is useful in relieving many of the symptoms of parkinsonism, particularly rigidity and bradykinesia. It is frequently helpful in the management of tremor, dysphagia, sialorrhoea, and postural instability associated with Parkinson's disease and syndrome.

When response to levodopa alone is irregular, and signs and symptoms of Parkinson's disease are not controlled evenly through the day, substitution of Sinemet usually reduces fluctuations in response. By reducing certain adverse reactions produced by levodopa alone, Sinemet permits more patients to obtain adequate relief of the symptoms of Parkinson's disease.

Sinemet may be given to patients with Parkinson's disease and syndrome who are taking vitamin preparations that contain pyridoxine.

Dosage and administration The optimum daily dosage of Sinemet must be determined by careful titration for each patient.

Sinemet Tablets are available as:

Sinemet-110 containing 10 mg carbidopa and 100 mg levodopa.

Sinemet-Plus containing 25 mg carbidopa and 100 mg levodopa.

Sinemet-275 containing 25 mg carbidopa and 250 mg levodopa.

General considerations: Studies show that the peripheral enzyme dopa decarboxylase is fully inhibited (saturated) by carbidopa at doses between 70 and 100 mg a day. The formulations of Sinemet are designed to provide a range of doses with sufficient carbidopa to inhibit peripheral dopa decarboxylase and thus exert optimal therapy.

Patients who require less than 700 mg levodopa given as Sinemet-275 will theoretically not receive sufficient carbidopa to saturate peripheral dopa decarboxylase. Sinemet-Plus may be helpful, especially for patients with nausea and vomiting.

Most patients can be maintained on divided doses of three to six tablets of Sinemet-275 a day. Tablets are scored for easy division should the frequency of daily dosage need to be increased. During the titration period, Sinemet-Plus may be more convenient.

Patients on Sinemet-Plus who need a higher dosage should be switched to Sinemet-275. Dosage with either form should not exceed eight tablets a day. If patients do show a need for higher doses, levodopa should be added.

Because both beneficial and adverse effects are seen more rapidly with Sinemet than with levodopa, patients should be carefully monitored during the dosage adjustment period. Involuntary movements, particularly ble-

pharospasm, is a useful early sign of excess dosage in some patients.

Sinemet-110 can be used as an alternative to Sinemet-Plus.

Patients not receiving levodopa: Dosage may be initiated with one tablet of Sinemet-Plus three times a day, and adjusted as necessary by small increments to a maximum daily dosage of eight tablets. If patients need more levodopa, one tablet of Sinemet-275 should be substituted three or four times a day. If further titration is necessary, the dosage of Sinemet-275 may be increased gradually to a maximum of eight tablets a day.

Patients receiving levodopa: Discontinue levodopa at least twelve hours (24 hours for slow-release preparations) before starting therapy with Sinemet. The easiest way to do this is to give Sinemet as the first morning dose after a night without any levodopa. The dose of Sinemet should be approximately 20% of the previous daily dosage of levodopa.

The suggested starting dose for most patients is one tablet of Sinemet-275 three or four times a day.

Patients requiring less than 1,500 mg levodopa a day should be started on one tablet of Sinemet-Plus three or four times a day.

The dosage may then be adjusted gradually, but this should not exceed eight tablets a day.

Patients receiving levodopa with another decarboxylase inhibitor: When transferring a patient to Sinemet from levodopa combined with another decarboxylase inhibitor, its dosage should be discontinued at least twelve hours before Sinemet is started. Begin with a dosage of Sinemet that will provide the same amount of levodopa as contained in the other levodopa/decarboxylase inhibitor combination.

Patients receiving other antiparkinsonian agents: Current evidence indicates that other standard antiparkinsonian agents may be continued when Sinemet is introduced (as indicated above), though dosage may have to be adjusted.

Contra-indications, warnings, etc

Contra-indications: Concurrent use with monoamine oxidase inhibitors (these must be discontinued at least two weeks before starting Sinemet), narrow-angle glaucoma; known hypersensitivity to this medication.

Because levodopa may activate a malignant melanoma, it should not be used in patients with suspicious undiagnosed skin lesions or a history of melanoma.

See also 'Pregnancy and lactation' under 'Precautions'.

Precautions: Sinemet may be given to patients already receiving levodopa alone; however, the levodopa must be discontinued at least 12 hours before Sinemet is started. Sinemet should be substituted at a dosage that will provide approximately 20% of the previous levodopa dosage (see 'Dosage and administration').

Sinemet is not recommended for the treatment of drug-induced extrapyramidal reactions. Sinemet should be administered cautiously to patients with severe cardiovascular or pulmonary disease, bronchial asthma, renal, hepatic or endocrine disease.

All patients should be monitored carefully for the development of mental changes, depression with suicidal tendencies, and other serious antisocial behaviour. Patients with current psychoses should be treated with caution. Patients with a history of severe involuntary movements or psychotic episodes when treated with levodopa alone should be observed carefully when Sinemet is substituted. These reactions are thought to be

due to increased brain dopamine following administration of levodopa, and use of Sinemet may cause a recurrence. Concomitant administration of psychoactive drugs such as phenothiazines and butyrophenones should be carried out with caution, and the patient carefully observed for loss of antiparkinsonian effect. Patients with a history of convulsions should be treated with caution.

Phenytoin and papaverine have been reported to reverse the beneficial effects of levodopa.

Patients with chronic wide-angle glaucoma may be treated cautiously with Sinemet, provided the intra-ocular pressure is well controlled and the patient monitored carefully for changes in intra-ocular pressure during therapy.

Care should be exercised when Sinemet is administered to patients with a history of myocardial infarction who have atrial, nodal or ventricular arrhythmias. Cardiac function should be monitored with particular care in such patients during the period of initial dosage adjustment.

As symptoms of postural hypotension have occasionally been reported, Sinemet should be given with caution to patients receiving antihypertensive agents. Adjustment of the dosage of the antihypertensive agent may be required when Sinemet is started. (For patients on pargyline, see the contra-indication on monoamine oxidase inhibitors.)

As with levodopa, there is a possibility of upper gastrointestinal haemorrhage in patients with a history of peptic ulcer. If general anaesthesia is required, therapy with Sinemet may be continued as long as the patient is permitted to take fluids and medication by mouth. If therapy is interrupted temporarily, the usual daily dosage may be administered as soon as the patient is able to take oral medication.

Transient abnormalities in laboratory test results may occur, but have not been associated with clinical evidence of disease. These include elevated blood urea, SGOT, SGPT, LDH, bilirubin, alkaline phosphatase, and protein-bound iodine levels.

Positive Coombs tests have been reported, both with Sinemet and levodopa alone, but haemolytic anaemia is extremely rare.

Usage in children: The safety of Sinemet in patients under 18 years of age has not been established.

Pregnancy and lactation: Although the effects of Sinemet on human pregnancy and lactation are unknown, both levodopa and combinations of carbidopa and levodopa have caused visceral and skeletal malformations in rabbits. Therefore, use of Sinemet in women of child-bearing potential requires that the anticipated benefits of the drug be weighed against possible hazards should pregnancy occur. Sinemet should not be given to nursing mothers.

Drug interactions: Clinical experience with concurrent administration of Sinemet and other standard antiparkinsonian drugs, e.g. benzotropine mesylate, benzhexol hydrochloride, is limited. To date, however, there has been no indication of interactions that would preclude concurrent use. No adverse reactions have been reported that do not occur with the various agents alone.

Side-effects: Side-effects that occur frequently with Sinemet are those due to the central neuropharmacological activity of dopamine. These reactions can usually be diminished by dosage reduction. The most common are choreiform, dystonic and other involuntary movements. Muscle twitching and blepharospasm may be taken as early signs to consider dosage reduction.

Less common are mental changes, including paranoid ideation and psychotic episodes; depression, with or without development of suicidal tendencies; and dementia. Convulsions have occurred, but a causal relationship has not been established.

Less frequent side-effects are cardiac irregularities and/or palpitations, orthostatic hypotensive episodes, bradykinetic episodes (the 'on-off' phenomenon), anorexia, nausea, vomiting and dizziness.

Gastro-intestinal bleeding, development of duodenal ulcer, hypertension, phlebitis, leucopenia and agranulocytosis have occurred rarely.

Positive Coombs tests have been reported both with Sinemet and with levodopa alone, but haemolytic anaemia is extremely rare.

Other side-effects that have been reported include:

Psychiatric: Euphoria, lethargy, sedation, stimulation, fatigue and malaise, confusion, insomnia, nightmares, hallucinations and delusions, agitation and anxiety.

Neurological: Ataxia, faintness, headache, increased hand tremor, trismus, oculogyric crisis, weakness, numbness, bruxism.

Gastro-intestinal: Constipation, diarrhoea, epigastric and abdominal distress and pain, flatulence, hiccups, sialorrhoea, difficulty in swallowing, bitter taste, dry mouth, burning sensation of the tongue.

Dermatological: Sweating, oedema, hair loss, rash, unpleasant odour, dark sweat.

Respiratory: Hoarseness, bizarre breathing pattern.

Urogenital: Urinary retention, incontinence, haematuria, dark urine, priapism.

Special senses: Blurred vision, diplopia, dilated pupils, activation of latent Horner's syndrome.

Other: Hot flushes, weight gain or loss, flushing, abnormalities in laboratory tests (see 'Precautions').

Treatment of overdosage: General supportive measures should be employed, along with immediate gastric lavage. Intravenous fluids should be administered judiciously, and an adequate airway maintained. ECG monitoring should be instituted, and the patient carefully observed for the possible development of arrhythmias; if required, appropriate anti-arrhythmic therapy should be given.

The possibility that the patient may have taken other drugs as well as Sinemet should be taken into consideration. To date, no experience has been reported with dialysis, and hence its value in the treatment of overdosage is not known. Pyridoxine has no effect in reversing the effects of Sinemet.

Pharmaceutical precautions Keep container tightly closed; store in a cool place, protected from light.

Legal category POM.

Package quantities Bottles of 100.

Further information Levodopa relieves the symptoms of Parkinson's disease, presumably by being decarboxylated to dopamine in the brain. Carbidopa, which does not cross the blood-brain barrier, inhibits only the extracerebral decarboxylation of levodopa, making more levodopa available for transport to the brain and subsequent conversion to dopamine. This obviates the need for large doses of levodopa at frequent intervals. The lower dosage reduces or eliminates many adverse reactions, some of which are attributable to dopamine being formed in extracerebral tissues.

11 PARA-AMINOHIPPURATE

Preparation A clear, colourless to slightly yellow solution for intravenous injection, containing in each ml of sterile solution 2 g sodium para-aminohippurate. Active ingredient: Sodium Hydroxide BP.

Uses As a diagnostic agent for the estimation of effective renal plasma flow (RPF). In research procedures, for the measurement of the functional capacity of the renal tubular secretory mechanism (Tm_{PAH}).

Dosage and administration For intravenous use only.

For the measurement of RPF, the concentration of sodium para-aminohippurate in the plasma is maintained at 2 mg per 100 ml. As a research procedure for the measurement of Tm_{PAH} , the plasma level of sodium para-aminohippurate must be sufficient to saturate the capacity of the tubular secretory cells. Concentrations of from 40 to 60 mg per 100 ml are necessary.

Contra-indications, warnings, etc

Precautions: Intravenous solutions must be administered with caution in patients with low cardiac reserve, since a rapid increase in plasma volume can precipitate congestive heart failure.

For measurement of RPF, small doses of sodium para-aminohippurate are used. However, in research procedures for Tm_{PAH} determinations high plasma levels are required to saturate the capacity of the tubular cells. During these procedures the intravenous administration of sodium para-aminohippurate solutions should be carried out slowly and with caution. The patient should be continuously observed for any adverse reactions.

Renal clearance measurement of sodium para-aminohippurate cannot be made with any significant accuracy in patients receiving sulphonamides, procaine or thiazolesulphone. These compounds interfere with chemical colour development essential to the analytical procedures.

Probenecid depresses tubular secretion of certain weak acids such as sodium para-aminohippurate. Therefore patients receiving probenecid will have erroneously low RPF and Tm_{PAH} values.

Effects: Vasomotor disturbances, flushing, tingling, vomiting, cramps. Patients may have a sensation of heat or the desire to defaecate or urinate during or after the administration of a primary dose.

Effect of overdosage: Not applicable.

Precautions No special requirements.

Form POM.

Containers Vials of 10 ml and 50 ml.

Instructions for use Methods of calculating renal plasma flow found in the package leaflet.

Product number 0025/5080.

Trade name

colourless to light yellow, sterile

Uses

glaucoma, reduction of intra-ocular pressure, conditions, hypertension, coma, including secondary glaucoma

Dosage and administration

is one drop 0.25% solution 4 times a day.

If clinical response is not obtained, the dose may be changed to one drop 0.5% solution 4 times a day. If needed, the dose may be increased with miotics, adrenaline or sympathomimetics, but not with carbonic anhydrase inhibitors.

Intra-ocular pressure should be reassessed approximately four weeks after starting treatment because response to Timoptol may take a few weeks to stabilise.

Provided that the intra-ocular pressure is maintained at satisfactory levels, many patients can then be placed on once-a-day therapy. Because of naturally occurring diurnal variations in intra-ocular pressure, satisfactory response is best determined by measuring the intra-ocular pressure at different times during the day.

Transfer from other agents: When only a single antiglaucoma agent is being used, continue the agent and add one drop of 0.25% Timoptol in each affected eye twice a day. On the following day, discontinue the previous agent completely, and continue with Timoptol. If a higher dosage of Timoptol is required, substitute one drop of 0.5% solution in each affected eye twice a day.

When several antiglaucoma agents are being used, the patient should be assessed individually. It may be possible to discontinue some or all the other agents; adjustments should be made to one agent at a time.

Clinical trials have shown the addition of Timoptol to be useful in patients who respond inadequately to maximum antiglaucoma drug therapy.

Contra-indications, warnings, etc

Contra-indications: Bronchospasm, including bronchial asthma, or chronic obstructive pulmonary disease; uncontrolled cardiac failure; and hypersensitivity.

Precautions: Like other topically applied ophthalmic drugs, Timoptol may be absorbed systemically. Timoptol should be used with caution in patients with known contra-indications to systemic use of beta-adrenergic receptor blocking agents. These include sinus bradycardia and greater than first degree heart block; cardiogenic shock; diabetes, especially labile diabetes. Cardiac failure should be adequately controlled before beginning therapy with Timoptol. Patients with a history of severe cardiac disease should be watched for signs of cardiac failure and have their pulse rates checked.

Patients who are already on an oral beta-adrenergic blocking agent should be observed for a potential additive effect on either intra-ocular pressure or the known systemic effects of beta-blockade when given Timoptol.

Although Timoptol alone has little or no effect on pupil size, mydriasis has occasionally been reported when Timoptol is given with adrenaline.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenergic receptor blocking drugs. The reported incidence is small and is

When treatment with the drug should be initiated, it is not otherwise explicitly contraindicated by involving beta-blockade.

Contraindications: Timoptol has not been studied in pregnancy. The use of Timoptol requires that the potential benefit be weighed against possible hazards.

Use in children: Since clinical studies in children have not been conducted, Timoptol is not currently recommended for use in children.

Side-effects: Timoptol is usually well tolerated.

Signs and symptoms of ocular irritation, including conjunctivitis, blepharitis, and keratitis have been reported occasionally. Visual disturbances including refractory changes (due to withdrawal of miotic therapy) have been reported infrequently.

Hypersensitivity reactions, including localised and generalised rash, and urticaria, have been reported rarely.

Aggravation or precipitation of certain cardiovascular, pulmonary and other disorders have been reported, presumably related to the effects of beta blockade. These include bradyarrhythmia, hypotension, syncope, and bronchospasm (predominantly in patients with pre-existing bronchospastic disease). Respiratory failure, congestive heart failure and masked symptoms of hypoglycaemia in insulin-dependent diabetes have been reported rarely. In clinical trials, slight reduction of the resting heart rate in some patients (mean reduction 2.9 beats/minute, standard deviation 10.2) has been observed.

The following adverse effects have been reported rarely, and a causal relationship to Timoptol has not been established: aphakic cystoid macular oedema, headache, dry mouth, anorexia, dyspepsia, nausea, dizziness, CNS effects, (fatigue, confusion, depression, somnolence, and anxiety), palpitation, and hypertension.

Pharmaceutical precautions Timoptol is stable at room temperature.

Legal category POM.

Package quantities Both the 0.25% and 0.5% w/v solution of timolol maleate are presented in special metered-dose Ocumeter® dispensers, each containing 5 ml.

Further information Unlike miotics, Timoptol reduces IOP with little or no effect on accommodation or pupil size. In patients with cataracts, the inability to see around lenticular opacities when the pupil is constricted is avoided. When changing patients from miotics to Timoptol a refraction might be necessary when these effects of the miotic have passed.

Diminished response after prolonged therapy with Timoptol has been reported in some patients.

Timoptol has been generally well tolerated in glaucoma patients wearing conventional hard contact lenses. Timoptol has not been studied in patients wearing lenses made with material other than polymethylmethacrylate (PMMA).

0.5% Ophthalmic Solution	0025/0136

TYROZETS®

Presentation Pink, aniseed-flavoured lozenges,

marked 'MSD' one side and Tyrozets the other, containing 1 mg tyrothricin and 5 mg Benzocaine.

Uses Antibiotic and local analgesic-anaesthetic.

For minor mouth and throat irritations; irritation following tonsillectomy and other oral and throat surgery.

Dosage and administration *Usual dosage:* 1 lozenge every three hours; maximum, 8 lozenges in 24 hours. An adequate response is not evident within two hours; consider stopping Tyrozets.

To allow maximum contact with inflamed tissue Tyrozets should not be chewed or swallowed whole, but allowed to dissolve slowly in the mouth.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to tyrothricin or to benzocaine. If evidence of sensitivity occurs during therapy, Tyrozets should be discontinued.

Precautions: The use of antibiotics may cause overgrowth of non-susceptible organisms. If new infections due to bacteria or fungi appear during therapy, Tyrozets should be stopped and appropriate measures taken.

Topical use of Tyrozets as an aid to prevention of local infection in no way alters the need for adequate systemic therapy if an infection should develop.

Side-effects: Blackness or soreness of the tongue may occur, but usually disappears when therapy is stopped.

Treatment of overdose: Symptomatic and supportive; emesis should be induced or gastric lavage performed.

Pharmaceutical precautions Store in a cool, dry place.

Legal category P.

Package quantities Vials of 12 lozenges.

Further information Since tyrothricin is used only locally and has a low index of sensitisation and toxicity, cross-sensitisation with antibiotics used systemically in more serious infections is unlikely.

Product licence number 0025/5072.

VIRVINA®

Presentation Dark-brown elixir containing, in 5 ml, 0.676 mg Thiamine Hydrochloride BP (Vitamin B₁), 0.338 mg Riboflavin BP (Vitamin B₂), 0.02 mg Pyridoxine Hydrochloride BP (Vitamin B₆), 5 mg Nicotinamide BP, 21.5 mg calcium glycerophosphate, 43.5 mg sodium glycerophosphate, 4 mg of potassium glycerophosphate, and 2.5 mg manganese glycerophosphate, in a palatable base containing 17% alcohol.

Uses Tonic.

For the prevention or treatment of Vitamin B deficiency (but not pernicious anaemia).

Dosage and administration *Adults:* 15 ml three times a day before meals.

Children, 6 years old or over: 5-10 ml three times a day before meals.

Contra-indications, warnings, etc Hypersensitivity to any of the ingredients, or to alcohol, has been reported.

Overdosage: Should be treated symptomatically. Severe effects may be expected if taken together with symptomatic treatment for excessive heat.

Pharmaceutical precautions Store in a cool, dry place, closed, and protected from light.

SODIUM PARA-AMINOHIPPURATE

Presentation A clear, colourless to slightly yellow solution for intravenous injection, containing in each 10 ml of sterile solution 2 g sodium para-aminohippurate. Inactive ingredient: Sodium Hydroxide BP.

Uses As a diagnostic agent for the estimation of effective renal plasma flow (RPF). In research procedures, for the measurement of the functional capacity of the renal tubular secretory mechanism (Tm_{PAH}).

Dosage and administration For intravenous use only.

For the measurement of RPF, the concentration of sodium para-aminohippurate in the plasma is maintained at 2 mg per 100 ml. As a research procedure for the measurement of Tm_{PAH} , the plasma level of sodium para-aminohippurate must be sufficient to saturate the capacity of the tubular secretory cells. Concentrations of from 40 to 60 mg per 100 ml are necessary.

Contra-indications, warnings, etc

Precautions: Intravenous solutions must be administered with caution in patients with low cardiac reserve, since a rapid increase in plasma volume can precipitate congestive heart failure.

For measurement of RPF, small doses of sodium para-aminohippurate are used. However, in research procedures for Tm_{PAH} determinations high plasma levels are required to saturate the capacity of the tubular cells. During these procedures the intravenous administration of sodium para-aminohippurate solutions should be carried out slowly and with caution. The patient should be continuously observed for any adverse reactions.

Renal clearance measurement of sodium para-aminohippurate cannot be made with any significant accuracy in patients receiving sulphonamides, procaine or thiazolesulphone. These compounds interfere with chemical colour development essential to the analytical procedures.

Probenecid depresses tubular secretion of certain weak acids such as sodium para-aminohippurate. Therefore, patients receiving probenecid will have erroneously low RPF and Tm_{PAH} values.

Side-effects: Vasomotor disturbances, flushing, tingling, nausea, vomiting, cramps. Patients may have a sensation of warmth or the desire to defaecate or urinate during or shortly after the administration of a primary dose.

Treatment of overdosage: Not applicable.

Pharmaceutical precautions No special requirements.

Legal category POM.

Package quantities Vials of 10 ml and 50 ml.

Further information Methods of calculating renal function are to be found in the package leaflet.

Product licence number 0025/5080.

TIMOPTOL®

Presentation Clear, colourless to light yellow, sterile

eye drops, available as a 0.25% and 0.5% w/v solution of timolol maleate.

Uses Timoptol Ophthalmic Solution is a beta-adrenergic receptor blocking agent used topically in the reduction of elevated intra-ocular pressure in various conditions including the following: patients with ocular hypertension; patients with chronic open-angle glaucoma including aphakic patients; some patients with secondary glaucoma.

Dosage and administration Recommended therapy is one drop 0.25% solution in the affected eye twice a day.

If clinical response is not adequate, dosage may be changed to one drop 0.5% solution in each affected eye twice a day. If needed, Timoptol may be used with miotics, adrenaline or systemically-administered carbonic anhydrase inhibitors.

Intra-ocular pressure should be reassessed approximately four weeks after starting treatment because response to Timoptol may take a few weeks to stabilise.

Provided that the intra-ocular pressure is maintained at satisfactory levels, many patients can then be placed on once-a-day therapy. Because of naturally occurring diurnal variations in intra-ocular pressure, satisfactory response is best determined by measuring the intra-ocular pressure at different times during the day.

Transfer from other agents: When only a single antiglaucoma agent is being used, continue the agent and add one drop of 0.25% Timoptol in each affected eye twice a day. On the following day, discontinue the previous agent completely, and continue with Timoptol. If a higher dosage of Timoptol is required, substitute one drop of 0.5% solution in each affected eye twice a day.

When several antiglaucoma agents are being used, the patient should be assessed individually. It may be possible to discontinue some or all the other agents; adjustments should be made to one agent at a time.

Clinical trials have shown the addition of Timoptol to be useful in patients who respond inadequately to maximum antiglaucoma drug therapy.

Contra-indications, warnings, etc

Contra-indications: Bronchospasm, including bronchial asthma, or chronic obstructive pulmonary disease; uncontrolled cardiac failure; and hypersensitivity.

Precautions: Like other topically applied ophthalmic drugs, Timoptol may be absorbed systemically. Timoptol should be used with caution in patients with known contra-indications to systemic use of beta-adrenergic receptor blocking agents. These include sinus bradycardia and greater than first degree heart block; cardiogenic shock; diabetes, especially labile diabetes. Cardiac failure should be adequately controlled before beginning therapy with Timoptol. Patients with a history of severe cardiac disease should be watched for signs of cardiac failure and have their pulse rates checked.

Patients who are already on an oral beta-adrenergic blocking agent should be observed for a potential additive effect on either intra-ocular pressure or the known systemic effects of beta-blockade when given Timoptol.

Although Timoptol alone has little or no effect on pupil size, mydriasis has occasionally been reported when Timoptol is given with adrenaline.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenergic receptor blocking drugs. The reported incidence is small and in

most cases the symptoms have cleared when treatment was withdrawn. Discontinuation of the drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy involving beta-blockade should be gradual.

Use in pregnancy: Timoptol has not been studied in human pregnancy. The use of Timoptol requires that the anticipated benefit be weighed against possible hazards.

Use in children: Since clinical studies in children have not been conducted, Timoptol is not currently recommended for use in children.

Side-effects: Timoptol is usually well tolerated.

Signs and symptoms of ocular irritation, including conjunctivitis, blepharitis, and keratitis have been reported occasionally. Visual disturbances including refractory changes (due to withdrawal of miotic therapy) have been reported infrequently.

Hypersensitivity reactions, including localised and generalised rash, and urticaria, have been reported rarely.

VIRVINA®

Presentation Dark-brown elixir containing, in each 5 ml, 0.676 mg Thiamine Hydrochloride BP (Vitamin B₁), 0.338 mg Riboflavin BP (Vitamin B₂), 0.017 mg Pyridoxine Hydrochloride BP (Vitamin B₆), 5 mg Nicotinamide BP, 21.5 mg calcium glycerophosphate, 43.5 mg sodium glycerophosphate, 4 mg of potassium glycerophosphate, and 2.5 mg manganese glycerophosphate, in a palatable base containing 17% alcohol.

Uses Tonic.

For the prevention or treatment of Vitamin B deficiency (but not pernicious anaemia).

Dosage and administration *Adults:* Usually 10–15 ml three times a day before meals.

Children, 6 years old or over: 5–10 ml three times a day before meals.

Contra-indications, warnings, etc No side-effects have been reported.

Overdose: Should be treated as for ethyl alcohol, together with symptomatic and supportive measures.

Pharmaceutical precautions Keep container tightly closed, and protected from sunlight and excessive heat.

Legal category P.

Package quantities Bottles of 200 ml and 1,000 ml.

Further information Nil.

Product licence number 0025/5073.

ZINAMIDE*

Presentation White, half-scored tablets, marked 'MSD 504', containing 500 mg Pyrazinamide BP.

Uses Antituberculous agent.

Indicated in patients with active tuberculosis in whom problems of drug resistance or patient intolerance preclude therapy with some combination of isoniazid, streptomycin and/or para-aminosalicylic acid. Zinamide should be given only with other effective antituberculous agents.

Dosage and administration *Usual adult dosage:* 20–35 mg/kg a day divided into three or four doses; the maximum daily dosage is 3 g regardless of body weight. Zinamide should be administered with at least one other effective antituberculous drug. The use of Zinamide in combination therapy does not modify the accepted dosages of other antituberculous agents.

Contra-indications, warnings, etc

Contra-indications: Severe hepatic damage. Safety for use in children has not been established (see also 'Precautions').

Precautions: Zinamide should only be used when close daily observation of the patient is possible, and when laboratory facilities are available for performing frequent liver function tests and blood uric acid determinations. Pre-treatment examinations should include *in vitro* sensitivity tests of recent cultures of *M. tuberculosis* from the patient as measured against the usual antituberculous drugs. Liver function tests, especially serum glutamic pyruvic transaminase (SGPT) and serum glutamic oxaloacetic transaminase (SGOT) determinations, should be carried out prior to therapy, and then every two to four weeks during therapy. Therapy with Zinamide should be withdrawn and not reinstated if signs of hepatocellular damage occur.

If hyperuricaemia accompanied by an acute gouty arthritis occurs, therapy should be discontinued and not reinstated. Zinamide should be used with caution in

patients with a history of gout or diabetes mellitus, as their management may become more difficult.

The safety of Zinamide for use in children has not been established. Because of its potential toxicity, the use of Zinamide in children should be avoided unless it is considered crucial.

There has been one report that the use of Zinamide increased the incidence of fatal haemoptysis. Despite the absence of evidence confirming this, the possibility of an adverse effect on blood clotting time or vascular integrity should be considered.

Side-effects: A hepatic reaction is the most common side-effect of Zinamide. This varies from a symptomless abnormality of hepatic cell function, detectable only by laboratory tests, through a mild syndrome of fever, anorexia, malaise, liver tenderness, hepatomegaly and splenomegaly, to more serious reactions such as clinical jaundice, and rare cases of progressive fulminating acute yellow atrophy and death.

Other side-effects – active gout, sideroblastic anaemia, arthralgias, anorexia, nausea and vomiting, dysuria, malaise, fever, urticaria, aggravation of peptic ulcer.

Treatment of overdosage: The stomach should be emptied by emesis or gastric lavage. Short-acting barbiturates may be given for manifestations of CNS stimulation, anaesthetics for coma, and artificial respiration and oxygen for respiratory failure. In the event of shock, a vasopressor agent (e.g. Aramine, metaraminol tartrate, MSD – see separate entry) should be given.

Pharmaceutical precautions Keep container tightly closed; store in a cool place, protected from light.

Legal category POM.

Package quantities Bottles of 100 and 500. Pure pyrazinamide powder, for sensitivity tests, is available on request.

Further information Zinamide has been used with other 'second line' agents, such as ethionamide and cycloserine, in cases where all three 'standard' drugs were contra-indicated. The use of such combinations has produced sputum conversion in a high proportion of patients able to continue therapy for at least six months.

Product licence number 0025/5038.

CLOMID*

Presentation Beige, round, flat, bevelled tablets. The upper surface bisected and the lower surface engraved 'M' within two circles. Each tablet contains 50 mg Clomiphene Citrate BP.

Uses The treatment of ovulatory failure in women wishing to become pregnant. Clomid is indicated only in patients with ovarian dysfunction. Commonly associated diagnoses include polycystic ovary syndrome, lactation amenorrhoea syndrome, psychogenic amenorrhoea, and certain cases of secondary amenorrhoea of undetermined aetiology. An additional diagnosis is post-oral contraceptive amenorrhoea.

Dosage and administration The recommended dose for the first course of Clomid is 50 mg (1 tablet) daily for five days. When ovulation occurs at this dosage there is no advantage in increasing the dose in subsequent cycles of treatment. If ovulation occurs at this dosage but is not followed by pregnancy, subsequent courses for a total maximum of 6 cycles of Clomid treatment may be administered.

If ovulation appears not to have occurred after the first course of therapy, a second course of 100 mg daily (two 50 mg tablets given as a single daily dose) for five days should be given. If ovulatory menses do not occur, this dose may be repeated for two additional cycles, but failure to induce ovulation after 3 consecutive cycles at this dosage should constitute an adequate therapeutic trial. If, however, ovulation does occur at this dosage but is not followed by pregnancy, subsequent courses for a total maximum of 6 cycles of Clomid treatment may be administered. The importance of properly timed coitus cannot be overemphasised.

Therapy may be started at any time in a patient who has had no recent uterine bleeding; but if progestin-induced bleeding is planned, or if spontaneous uterine bleeding occurs prior to therapy, the course of Clomid should be started on or about the fifth day of the cycle.

Contra-indications *Pregnancy:* Although there is no evidence that Clomid has a harmful effect on the human foetus, Clomid does damage rat and rabbit foetuses when given in high doses to the pregnant animal. Therefore, Clomid should not be administered during pregnancy. To avoid inadvertent Clomid administration during early pregnancy, the basal body temperature should be recorded throughout all treatment cycles, and the patient should be carefully observed to determine whether ovulation occurs. If the basal temperature following Clomid is biphasic and is not followed by menses, the patient should be examined carefully and should have a pregnancy test.

Liver disease: Clomid should not be given to patients with known liver disease or a history of liver dysfunction.

Abnormal uterine bleeding: Clomid should not be given until the cause of the bleeding has been determined. It is most important to ensure that neoplastic lesions are not overlooked.

Precautions *Visual symptoms:* Patients should be advised that blurring or other visual symptoms may occasionally occur during Clomid therapy. The significance of these symptoms is not yet understood. If they do occur, Clomid should be discontinued; and a complete ophthalmological evaluation should be made. No further courses of Clomid should be administered.

Diagnosis prior to Clomid therapy: Careful evaluation and selection of patients, and close attention to dosage instructions, contra-indications and side-effects, are mandatory. Since Clomid is indicated only in patients with ovarian dysfunction, other possible causes of infertility should be excluded or treated before giving Clomid.

Pelvic examination should be made before each course of Clomid is given.

Overstimulation of the ovary during Clomid therapy: Since Clomid stimulates the ovaries, it may cause abnormal ovarian enlargement due to overstimulation in some patients. With the exception of patients with polycystic ovary syndrome, Clomid should not be given in the presence of an ovarian cyst, since further enlargement of the ovary may occur. Patients known to have polycystic ovaries should be given the smallest dose possible of Clomid with expectation of favourable results. It should be borne in mind that maximal ovarian enlargement may not occur until several days after the treatment cycle is completed. Patients who complain of pelvic pain after receiving Clomid should be examined with care. If enlargement of the ovary occurs, additional courses of Clomid should not be given until the ovaries have returned to pre-treatment size, and then a shorter course or smaller dose should be administered. Ovarian enlargement and cyst formation that are occasionally associated with Clomid therapy regress spontaneously within a few days or weeks after discontinuing treatment. Unless surgical indication for laparotomy exists, such cystic enlargement should be managed conservatively.

Multiple pregnancy: The incidence of multiple pregnancy is increased when conception takes place during a cycle in which Clomid is given. In a large series of closely monitored patients who became pregnant after receiving Clomid, there were 6.9% (165) twins, 0.5% (11) triplets, 0.3% (7) quadruplets and 0.13% (3) quintuplets. Of these multiple pregnancies, 357 live infants were born of 165 multiple births. After excluding 60 neonatal deaths, 297 survived, including 27 of 61 live infants from triplet, quadruplet and quintuplet pregnancies. In addition, one sextuplet pregnancy has been reported in a patient treated with Clomid. Patients (and their husbands)

should be advised of the possibility and potential complications of multiple pregnancy associated with Clomid therapy.

Side-effects Side-effects are not prominent and infrequently interfere with treatment when the recommended dosage of Clomid is given.

Side-effects are dose-related, being more frequent and more severe when higher doses of Clomid are administered.

The more common side-effects are hot flushes, abdominal discomfort (distension, bloating, pain or soreness), ovarian enlargement and visual blurring. The vasomotor symptoms resembling menopausal hot flushes are not usually severe and disappear soon after treatment is discontinued. Abdominal symptoms are most often related to ovulatory (*mittelschmerz*) or premenstrual phenomena, or to ovarian enlargement. At recommended dosage the normal variation in ovarian size may be exaggerated. Rare instances of massive ovarian enlargement and rupture of a lutein cyst with haemoperitoneum have been reported.

Visual symptoms, described usually as 'blurring' or spots or flashes (scintillating scotomata), increased in incidence with increasing total dose and disappeared within a few days or weeks after Clomid was discontinued. These symptoms appear to be due to intensification and prolongation of after-images. Symptoms often first appear or are accentuated with exposure to a more brightly lit environment. While measured visual acuity has not generally been affected, one patient taking 200 mg daily developed visual blurring on the seventh day of treatment, which progressed to severe diminution of visual acuity by the tenth day. No other abnormality was found and the visual acuity returned to normal on the third day after treatment was stopped. One patient treated during clinical studies developed scotomata during prolonged Clomid administration, which disappeared by the 32nd day after stopping therapy.

The following conditions have been reported in association with Clomid therapy: relationship of cause and effect has neither been proved nor disproved; Ophthalmologically definable scotomata and retinal cell function (electroretinographic) changes have also been reported.

Posterior capsular cataract (4, all in investigational studies), detachment of the posterior vitreous (1), spasm of retinal arteriole (1), in original 2,369 investigational pregnancies.

Other less frequently reported symptoms included nausea or vomiting, increased nervous tension, depression, fatigue, dizziness or lightheadedness, insomnia, headache, breast soreness, heavier menses, intermenstrual spotting, weight gain, urticaria and allergic dermatitis, increased urinary frequency and moderate reversible hair loss.

Defects at birth have been reported in 58 infants from 2,369 delivered pregnancies in mothers treated with Clomid. Four of the infants were in the abortion/stillbirth category, 14 were from multiple pregnancies, and the remaining were single births. The defects have included Down's syndrome (5 infants), congenital heart lesions (8 infants), microcephaly (2 infants), harelip and cleft palate (2 infants), hypospadias (3 infants), undescended testes (2 infants), club foot (4 infants), gastro-intestinal malformations (4 infants), congenital hip (2 infants) and polydactyly (both of twins).

Eight of the total of 58 infants were born to 7 of 158

mothers who received (inadvertently) a course of Clomid during the first six weeks after conception.

Clomid, when given continuously for prolonged periods, may interfere with cholesterol synthesis. Serum from patients treated in this way appears to have elevated desmosterol levels. In patients taking recommended doses of Clomid serum sterol patterns are not significantly altered.

Bromsulphthalein (BSP) retention of greater than 5% has been reported in 32 of 141 patients in whom it was measured. Other liver function tests were usually normal. Retention was usually minimal unless associated with prolonged continuous Clomid administration or with apparently unrelated liver disease. In some patients, pre-existing BSP retention decreased even though Clomid therapy was discontinued. One patient developed jaundice on the 14th day of Clomid treatment; liver biopsy revealed bile stasis without evidence of hepatitis. Clomid has not been reported to cause significant abnormality in the haematopoietic or renal systems, the protein-bound iodine or in serum cholesterol.

Overdosage There is no experience of overdosage with Clomid.

Pharmaceutical precautions Clomid tablets should be protected from light, moisture and excessive heat.

Legal category POM.

Package quantities Clomid is obtainable in packs of 30 and 100 tablets in blister packs.

Further information Clomid is prescribable under the supervision of an appropriate specialist.

Pharmacological classification: Clomid is a triarylethylene compound (related to chlorotrianisene and triparanol). It is a non-steroidal agent taken by mouth which stimulates ovulation in a high percentage of appropriately selected anovulatory women.

Actions: The ovulatory response to cyclic Clomid therapy appears to be mediated through increased output of pituitary gonadotrophins, which in turn stimulates the maturation and endocrine activity of the ovarian follicle and the subsequent development and function of the corpus luteum. The role of the pituitary is indicated by increased urinary excretion of gonadotrophins and the response of the ovary is manifested by increased urinary oestrogen excretion.

Product licence number 4425/5900.

DEBENDOX*

Presentation White, round, biconvex tablet containing:

Decapryn (doxylamine succinate USNF 1975)	10 mg
Pyridoxine Hydrochloride BP	10 mg

in a special timed-release coating designed to release active ingredients four to six hours after ingestion.

Uses Debendox is indicated for nausea and vomiting of pregnancy which are unresponsive to conservative measures and are sufficiently distressing to require drug intervention.

Dosage and administration Two tablets at bedtime. In severe cases or when nausea occurs during the day, 1 additional tablet on arising and another in mid-afternoon.

Contra-indications, warnings, etc *Contra-indications:* Known idiosyncrasy to any of the ingredients.

Precautions: Because of potential drowsiness, patients should be warned not to engage in activities requiring mental alertness such as operating motor vehicles or other machinery, or perform hazardous work, while taking Debendox.

There have been a large number of epidemiological studies of Debendox. Although there have been some reports of congenital malformations associated with its administration in early pregnancy, a causal relationship has not been established.

For no medicinal product can a small risk of teratogenic effect be excluded with absolute certainty and so the use of any drug during early pregnancy should be avoided if at all possible.

Side-effects: Doxylamine succinate may cause drowsiness; vertigo; nervousness; epigastric pain; headache; palpitation; diarrhoea; disorientation; or irritability. Pyridoxine hydrochloride is a vitamin that is generally recognised as having no adverse effects.

Overdosage: The tablets are designed to release their active ingredients four to six hours after ingestion. On one occasion intense purging produced recognisable tablets per rectum. Gastric lavage, emetics, and Universal Antidote (activated charcoal 2 parts, tannic acid 1 part, magnesium oxide 1 part) are recommended.

Because of the delayed release characteristics of Debendox, symptoms of overdosage may not become evident for some hours after ingestion of the tablets. It is recommended that patients who have or may have taken an overdose be admitted without delay to hospital for treatment or observation.

Pharmaceutical precautions Debendox Tablets should be stored in a cool dry place.

Legal category POM.

Package quantities Blister strips of 25 in packs of 50.

Further information Nil.

Product licence number 4425/5901.

DESTOLIT* ▼

Presentation Plain white tablet containing 150 mg ursodeoxycholic acid.

Uses Destolit is indicated for the dissolution of radiolucent (i.e. non-radio opaque) cholesterol gallstones in patients with a functioning gallbladder.

Dosage and administration The daily dose for most patients is 3 or 4 tablets of 150 mg according to body weight. This dose should be divided into 2 administrations after meals, with one administration always to be taken after the evening meal.

A daily dose of about 8 to 10 mg/kg will produce cholesterol desaturation of bile in the majority of cases. The measurement of the lithogenic index on bile-rich duodenal drainage fluid after 4-6 weeks of therapy may be useful for determining the minimal effective dose. The lowest effective dose has been found to be 4 mg/kg.

The duration of treatment required to achieve gallstone dissolution will usually not be extended beyond 2 years and should be monitored by regular cholecystograms. Treatment should be continued for 3-4 months after the radiological disappearance of the gallstones.

Any temporary discontinuation of treatment, if prolonged for 3-4 weeks, will allow the bile to return to a state of supersaturation and will extend the total time required for litholysis. In some cases stones may recur after successful treatment.

Contra-indications, warnings, etc In common with all drugs, it is advised that ursodeoxycholic acid should not be given during the first trimester of pregnancy. (In the rabbit, embryotoxicity has been observed, but this has not been seen in the rat.) Treatment in women of child-bearing age should only be undertaken if measures to prevent pregnancy are used. Non-hormonal contraceptive measures are recommended. In cases of conception during treatment, therapy should be discontinued. Active gastric or duodenal ulcers are contra-indications, as are hepatic and intestinal conditions interfering with the enterohepatic circulation of bile acids (ileal resection and stoma, regional ileitis, extra and intra-hepatic cholestasis, severe, acute, and chronic liver diseases). A product of this class has been found to be carcinogenic in animals. The relevance of these findings to the clinical use of ursodeoxycholic acid has not been established.

Excessive dietary intake of calories and cholesterol should be avoided; a low cholesterol diet will probably improve the effectiveness of Destolit tablets. It is also recommended that drugs known to increase cholesterol elimination in bile, such as oestrogenic hormones, oral contraceptive agents and certain blood cholesterol lowering agents should also not be prescribed concomitantly.

Side-effects: Destolit is normally well tolerated. Diarrhoea has been found to occur only occasionally. No significant alterations have so far been observed in liver function.

Overdosage: It is unlikely that overdosage will cause serious adverse effects. Diarrhoea may occur and it is recommended that liver function tests be monitored. Ion-exchange resins may be useful to bind bile acids in the intestines.

Pharmaceutical precautions Destolit tablets have a shelf life of 3 years under normal room temperature storage conditions.

Legal category POM.

Package quantities Blister packs of 60 tablets.

Further information Nil.

Product licence number 4425/0045.

KOLANTICON* GEL

Presentation Kolanticon Gel is a white, viscous, peppermint-flavoured suspension, each 5 ml containing:

Merbentyl* (Dicyclamine Hydrochloride BP)	2.5 mg
Dried Aluminium Hydroxide Gel BP	200 mg
Light Magnesium Oxide BP	100 mg
Dimethylsiloxane BPC	20 mg

Uses Kolanticon is an antacid-antiflatulent-anti-spasmodic-demulcent indicated for the treatment and prophylaxis of symptoms of peptic ulcer and functional dyspepsia especially in patients in whom gastric distress results from hyperacidity, smooth muscle spasm and flatulence. Also indicated for symptomatic relief in oesophagitis, hiatus hernia, gastritis and iatrogenic gastritis.

Dosage and administration Two to four 5 ml spoonfuls every four hours as required.

Contra-indications Known idiosyncrasy to any of the ingredients.

Precautions Magnesium salts, in the presence of renal insufficiency, may cause central nervous system depression. Aluminium hydroxide, in the presence of low phosphorus diets, may cause phosphorus deficiency. Aluminium hydroxide may reduce absorption of tetracyclines when given concomitantly. Products containing dicyclomine hydrochloride should be used with caution in any patient with or suspected of having, glaucoma. Use with care in patients with hiatus hernia associated with reflux oesophagitis because anticholinergic drugs may aggravate this condition.

Side-effects In particularly sensitive patients dicyclomine hydrochloride may cause atropine-like side-effects such as dry mouth, blurred vision, urinary retention or constipation.

Overdosage Signs and symptoms of dicyclomine hydrochloride overdose include: headache, nausea and vomiting, blurred vision, dilated pupils, hot dry skin, dizziness, vertigo, dryness of mouth, difficulty in swallowing, and CNS stimulation.

Treatment should include: Universal Antidote (activated charcoal 2 parts, tannic acid 1 part, magnesium oxide 1 part), emetics, gastric lavage, barbiturates for sedation, pilocarpine 0.01 g subcutaneously every half-hour until the mouth becomes moist.

Pharmaceutical precautions *Kolanticon Gel*: Store in a cool place. Shake well before use.

Legal category P.

Package quantities *Kolanticon Gel*: Amber glass bottles of 125 ml and 500 ml.

Further information Nil.

Product licence number 4425/0032.

KOLANTYL* GEL AND TABLETS

Presentation *Kolantyl Gel* is a white, viscous, peppermint-flavoured suspension, each 5 ml containing:

Merbentyl* (Dicyclomine Hydrochloride BP)	2.5 mg
Dried Aluminium Hydroxide Gel BP	200 mg
Light Magnesium Oxide BP	100 mg

Kolantyl Tablets are white, round tablets, marked 'K' inside two concentric circles. Each tablet contains:

Merbentyl (Dicyclomine Hydrochloride BP)	5 mg
Magnesium Trisilicate BP	90 mg
Dried Aluminium Hydroxide Gel BP	240 mg
Magnesium Hydroxide BPC	144 mg

Uses Antacid and antispasmodic for the treatment of symptoms of peptic ulcer and for prophylaxis in the ulcer-prone patient: for the relief of symptoms of gastric hyperacidity with or without pylorospasm in conditions such as: oesophagitis, hiatus hernia, and acute, iatrogenic and chronic gastritis.

Dosage and administration *Kolantyl Gel*: Two to four 5 ml spoonfuls every four hours as required.

Kolantyl Tablets: 1-2 chewed or allowed to dissolve in the mouth every four hours as required.

Contra-indications Known idiosyncrasy to any of the ingredients.

Precautions Magnesium salts, in the presence of renal insufficiency, may cause central nervous system depression. Aluminium hydroxide, in the presence of low phosphorus diets, may cause phosphorus deficiency. Aluminium hydroxide may reduce absorption of tetracyclines when given concomitantly. Products containing dicyclomine hydrochloride should be used with caution in any patient with, or suspected of having glaucoma. Use with care in patients with hiatus hernia associated with reflux oesophagitis because anticholinergic drugs may aggravate this condition.

Side-effects Side-effects are uncommon. When they occur, they are usually related to the dicyclomine hydrochloride in the formula, which, in a few susceptible individuals, may cause atropine-like side-effects. Such side-effects rarely necessitate a discontinuance of the drug.

Overdosage Universal Antidote (activated charcoal 2 parts, tannic acid 1 part, magnesium oxide 1 part), emetics, gastric lavage. Barbiturates and pilocarpine may be helpful when indicated.

Pharmaceutical precautions *Kolantyl Gel*: Store in a cool place. Shake well before use.

Kolantyl Tablets: None.

Legal category P.

Package quantities *Kolantyl Gel*: Bottles of 500 ml.

Kolantyl Tablets: Blister packs of 50.

Further information Nil.

<i>Kolantyl Gel</i>	0027/5002
<i>Kolantyl Tablets</i>	4425/0033

LURSELLE* ▼

Presentation Lurselle is presented as plain white, non-coated tablets imprinted on one face with the name 'Lurselle,' each tablet containing 250 mg probucol [4-4' (iso-propyldenedithio) bis (2,6-di-t-butylphenol)].

Uses Lurselle is indicated as ancillary therapy to diet for the reduction of elevated serum cholesterol in patients with hypercholesterolaemia, or in patients with combined hypercholesterolaemia and hypertriglyceridaemia where levels of cholesterol are a cause of concern.

Dosage and administration The recommended dose for adults is two tablets of 250 mg twice a day with the morning and evening meals.

Paediatric dosage has not yet been established.

Contra-indications, warnings, etc Reproduction studies in animals have not demonstrated any impairment of fertility or any harm to the foetus or offspring due to Lurselle. As yet there are no adequate studies in pregnant women, and the use of Lurselle during pregnancy is therefore not recommended. If a patient wishes to become pregnant, it is recommended that the drug be withdrawn and birth control procedures should be continued for at least six months due to the persistence of the drug in the fatty tissues of the body.

In animals it has been shown that some of the drug is excreted in the milk. It is recommended that nursing mothers should not be treated with Lurselle.

Before instituting therapy with Lurselle an attempt should be made to control elevated serum cholesterol by appropriate dietary regimens, weight reduction, and the treatment of any underlying disorder which might be the cause of the hypercholesterolaemia. Serum cholesterol and triglyceride levels should be monitored during the first months of treatment with Lurselle and periodically thereafter.

A favourable trend in cholesterol reduction should be evident during the first two months of Lurselle administration. An assessment should be made by the sixth month whether adequate reduction is being attained. A discontinuation in Lurselle treatment is usually followed by a gradual return of cholesterol to pre-treatment values.

If a marked sustained rise in serum triglycerides occurs during Lurselle therapy, consideration should be given to improving dietary compliance; alcohol abstinence; further restriction of calories, or adjustment of carbohydrate intake. If hypertriglyceridaemia persists, Lurselle should be discontinued.

Overdosage: In cases of overdosage symptomatic treatment and supportive measures should be instituted according to the individual symptoms.

Side-effects: The side effects associated with Lurselle are generally mild to moderate and of short duration. They include diarrhoea, which occurs in about one in 10 patients, flatulence, abdominal pain, nausea and vomiting. These reactions are usually transient and seldom require the drug to be discontinued.

During the clinical studies in which patients have been treated for as long as 9 years, Lurselle had to be discontinued in less than 3 percent of the patients because of adverse gastrointestinal reactions.

Angio-neurotic oedema has been observed very occasionally and a single hypersensitivity reaction with dizziness, palpitation and syncope has been reported.

Concomitant Therapy

The dosage of hypoglycaemic agents and oral anticoagulants need not usually be modified when given with Lurselle and these drugs do not alter the effect of Lurselle on serum cholesterol.

Administration of Lurselle with a second lipid lowering drug has been shown to produce further significant reductions in serum cholesterol. The most effective combinations were Lurselle with either ion exchange resins or nicotinic acid.

Pharmaceutical precautions Lurselle tablets should be stored in a well closed container, protected from light, heat and moisture.

Legal category POM.

Package quantities 120 tablets.

Further information Absorption of Lurselle from the gastrointestinal tract is limited; food intake improves absorption and consequently induces higher and less variable peak blood levels. Lurselle is eliminated slowly from the body; the major pathway of excretion is the biliary tract.

Studies in man on the mode of action of Lurselle are still underway but they have shown that Lurselle lowers serum cholesterol by increasing the excretion of bile acids and by inhibiting an early stage of cholesterol biosynthesis. In addition there may be a slight decrease in absorption of dietary cholesterol.

Studies with Lurselle have shown no evidence of biliary tract pathology or related gallstone formation.

Product licence number 4425/0043.

MERALEN*

Presentation Hard gelatin capsule with light blue body and dark blue cap. Both halves printed Merrell. Each 100 mg capsule contains Flufenamic Acid BP 100 mg.

Uses Meralen is an anti-inflammatory analgesic for the relief of pain in rheumatoid arthritis, osteoarthritis and ankylosing spondylitis.

Dosage and administration *Adults:* 600 mg daily, in divided doses, preferably with food. After four weeks continuous therapy, reduced maintenance dosage of 400 mg daily may be satisfactory in some patients. For those weighing less than 45 kg (100lb) dosage should not exceed 10 mg per kg body weight daily.

Children: Meralen should not be given to children of 14 years or less.

Contra-indications, warnings, etc Contra-indicated in pregnancy; in inflammatory bowel disease and in patients suffering from gastric and/or intestinal ulceration; and in renal or hepatic disease.

Precautions: Concurrent therapy with other plasma protein binding drugs, e.g. anticoagulants, may necessitate a modification in dosage.

Side-effects: Discontinue administration of Meralen if diarrhoea or abnormalities in liver function tests occur.

The commonest side-effect is gastro-intestinal upset, characterised by nausea, vomiting, or epigastric discomfort. If gastro-intestinal intolerance occurs and the physician attributes this to the drug, the dose of Meralen may be reduced by one half. If signs and symptoms do not subside, the drug may need to be completely discontinued. The physician may be able to increase the daily dosage of Meralen again, once these symptoms have subsided. In some patients the gastro-intestinal symptoms subside spontaneously without reduction of dosage of Meralen.

Meralen should be discontinued in the event of rash suspected to be a sensitivity reaction.

One case of purpura and four of leucopenia have been reported; one of the latter had been diagnosed as spontaneous leucopenia before Meralen therapy had commenced.

Bronchospasm may be precipitated in patients suffering from, or with a previous history of, bronchial asthma or allergic disease.

Overdosage: Gastric lavage in the conscious patient and intensive supportive therapy where necessary; activated charcoal has been shown to be a powerful absorbent for Meralen and its metabolites. Studies in experimental animals showed that a 5 to 1 ratio of charcoal resulted in considerable suppression of absorption of the drug.

Pharmaceutical precautions No special storage precautions.

Legal category POM.

Package quantities 100 mg capsules available in a pack of 100 capsules.

Further information Nil.

Product licence number 4425/0016R.

MERBENTYL* TABLETS AND SYRUP

Presentation Merbentyl Tablets are white, round, plain bi-convex tablets, stamped 'M' in two concentric circles, containing Dicyclomine Hydrochloride BP 10 mg.

Merbentyl Syrup is light red, bitter and raspberry flavoured. Each 5 ml contains 10 mg Dicyclomine Hydrochloride BP.

Uses Merbentyl is a smooth muscle antispasmodic primarily indicated for the treatment of *functional* conditions involving *smooth muscle spasm* of the gastrointestinal tract. The commonest of these are: irritable colon (mucous colitis, spastic colon), spastic constipation, infant colic.

Merbentyl can also be used as *adjunctive medication* in a number of organic gastro-intestinal conditions to relieve associated smooth muscle spasm, e.g. colitis, diverticulosis and diverticulitis, regional enteritis, gastritis, peptic ulcer, ulcerative colitis, cholelithiasis and cholecystitis (but not biliary colic).

Dosage and administration *Adults:* 1–2 tablets or one to two 5 ml spoonfuls (10–20 mg) three times daily before or after meals.

Children (2–12 years): 1–2 tablets or one to two 5 ml spoonfuls (10–20 mg) according to age, three times daily.

Children (6 months–2 years): 5–10 mg three or four times daily, 15 minutes before feeds. Do not exceed a daily dose of 40 mg. If it is necessary to dilute Merbentyl Syrup this may be done using Syrup BP or if diluted immediately prior to use with water.

Infants (up to 6 months): 5 mg three or four times daily, 15 minutes before feeds. Do not exceed daily dose of 20 mg. If it is necessary to dilute Merbentyl Syrup this may be done using Syrup BP or if diluted immediately prior to use with water.

Contra-indications Known idiosyncrasy to Dicyclomine Hydrochloride BP.

Precautions Products containing dicyclomine hydrochloride should be used with caution in any patient with, or suspected of having, glaucoma or prostatic hypertrophy. Use with care in patients with hiatal hernia associated with reflux oesophagitis because anticholinergic drugs may aggravate the condition.

There are rare reports of infants, 6 weeks of age and under, administered dicyclomine hydrochloride syrup, who have evidenced respiratory symptoms (breathing difficulty, shortness of breath, breathlessness, respiratory collapse, apnoea), as well as seizures, syncope, asphyxia, pulse rate fluctuations, muscular hypotonia and coma. The above symptoms have occurred within minutes of ingestion and lasted 20–30 minutes. The timing and nature of the reactions suggest that they were a consequence of local irritation and/or aspiration, rather than to a direct pharmacological effect. No known deaths or permanent adverse effects have been reported. Merbentyl Syrup should be used with caution in this age group.

Side-effects Side-effects seldom occur with Merbentyl. However, in susceptible individuals, dry mouth, thirst

and dizziness may occur. On rare occasions, fatigue, sedation, blurred vision, rash, constipation, anorexia, nausea and vomiting, headache, and dysuria have also been reported.

Overdosage Symptoms of Merbentyl overdosage are headache, dizziness, nausea, dry mouth, difficulty in swallowing, dilated pupils and hot dry skin. Treatment may include Universal Antidote (activated charcoal 2 parts, tannic acid 1 part, magnesium oxide 1 part), emetics, gastric lavage, pilocarpine 0.01 g subcutaneously every half-hour until mouth becomes moist. Barbiturates for sedation.

Pharmaceutical precautions *Merbentyl Tablets:* None.

Merbentyl syrup: Should be stored and dispensed in amber glass bottles.

Legal category POM.

Package quantities *Merbentyl Tablets:* Packs of 50 and 250 tablets.

Merbentyl Syrup: Amber glass bottles of 125 ml and 500 ml.

Further information Nil.

Product licence numbers

Merbentyl Tablets 0027/5007

Merbentyl Syrup 0027/5008

MEROCAINE*

Presentation Merocaine lozenges are green, round, slightly domed lozenges with 'M' indented on both sides. Each lemon/lime flavoured lozenge contains:

Cetylpyridinium Chloride BP 1.4 mg (1:1500)
Benzocaine Ph Eur 10 mg

Uses Merocaine lozenges provide rapid and profound local anaesthetic action and topical antibacterial effects for the temporary relief of pain and discomfort in sore throat and superficial mouth infections. Indicated for relief of minor throat irritations and, adjunctively, for symptomatic relief of pain and discomfort in more serious throat infections, such as tonsillitis and pharyngitis, and following dental procedures involving oral mucosa and gingival surfaces.

Dosage and administration Allow to dissolve slowly in the mouth. One lozenge every 2 hours as needed but not more than 8 lozenges in 24 hours. Not indicated for children under 12 years of age.

Contra-indications, warnings, etc

Contra-indications: Idiosyncrasy to any of the ingredients.

Side-effects: Allergic reactions and methaemoglobinemia have been reported with Benzocaine.

Overdosage: There is no experience of overdosage but normal procedures of gastric lavage and maintenance of respiration and circulation (using vasopressor drugs if necessary) should apply.

Pharmaceutical precautions None.

Legal category P.

Package quantities 3 strips of 8 lozenges per carton.

Further information Nil.

Product licence number 4425/0028.

MEROCKET* SOLUTION

Presentation Merocet Solution is a pale yellow, cinnamon-peppermint flavoured solution containing 1 : 2,000 Cetylpyridinium Chloride BP, Ethanol (96%) BP 14%, phosphate buffers and aromatics.

Uses Cetylpyridinium Chloride BP is a surface-active quaternary compound with bactericidal and anti-fungal properties. Merocet Solution is indicated for the symptomatic treatment of sore throat. It is also indicated for minor irritations of the mouth and throat and for use prophylactically in dentistry and after dental operations. Merocet Solution can also be used for daily oral hygiene.

Dosage and administration *Adults and children over six years:* The solution may be used full strength or diluted with an equal volume of water – warm if desired – every three hours, or as often as required.

Contra-indications, warnings, etc Known idiosyncrasy to cetylpyridinium chloride.

Precautions: None.

Side-effects: Infrequent and transient complaints of a burning sensation of the mouth.

Overdosage: There is no experience of overdosage.

Pharmaceutical precautions Avoid storage at low temperatures.

Legal category GSL.

Package quantities White flint-glass bottles of 200 ml.

Further information Nil.

Product licence number 4425/0017.

NETHAPRIN DOSPAN*

Presentation Nethaprin Dospan Tablets are white, round, flat, bevelled tablets, scored on one side and engraved 'N' on the other. Each tablet contains:

Nethamine* (etafedrine hydrochloride)	50 mg
Butaphyllamine* (bufylline)	180 mg
Decapryn* (doxylamine succinate USNF)	25 mg
Phenylephrine Hydrochloride BP	25 mg

Uses Nethaprin Dospan is a bronchodilator, anti-histamine, mild sedative, decongestant indicated for bronchospasm (wheezing) associated with chronic bronchitis, bronchial asthma or emphysema. Also useful in allergic cough.

Dosage and administration *Adults and children over 12 years:* For relief of mild to moderate attacks and for 12-hour protection: one tablet every 12 hours as required.

Children 6–12 years: $\frac{1}{2}$ tablet every 12 hours as required. Not recommended for children under 6 years.

Contra-indications Do not administer concurrently with monoamine oxidase inhibitors. Hypersensitivity.

Precautions This preparation may cause drowsiness; patients should be advised not to drive or operate machinery if affected.

It is dangerous to exceed the stated dose.

Side-effects While significant sympathomimetic side-effects have not been reported, an occasional sensitive patient may experience side-effects characteristic of this

class of medicine. Nausea or other gastro-intestinal upsets have been reported occasionally.

Overdosage Nethaprin Dospan is a sustained release formulation and releases active ingredients over 10–12 hours. Signs and symptoms of overdosage include salivation, diuresis, dryness of the mouth, excitement, hypertension, dilated pupils, convulsions, insomnia and tachycardia. Treatment may include emetics, gastric lavage, barbiturates, and the patient should be kept cool and quiet.

Pharmaceutical precautions Store in a cool dry place.

Legal category POM.

Package quantities Amber glass bottles of 50.

Further information Nil.

Product licence number 0027/5013.

NETHAPRIN* EXPECTORANT

Presentation Nethaprin Expectorant is an orange-red syrup, with a bitter-ginger flavour, each 5 ml containing:

Nethamine* (etafedrine hydrochloride)	20 mg
Butaphyllamine* (bufylline)	60 mg
Decapryn* (doxylamine succinate USNF)	6 mg
Glyceryl guaiacolate (USNF 1970)	100 mg

Uses Nethaprin Expectorant is a bronchodilator, anti-histamine, mild sedative, expectorant mixture indicated for the treatment of unproductive cough or excessive mucus production associated with bronchospasm (wheezing).

Dosage and administration *Adults and children over 12 years:* One to two 5 ml spoonfuls every three to four hours.

Children 6–12 years: One 5 ml spoonful every three to four hours.

Not recommended for children under 6 years.

Contra-indications Do not administer concurrently with monoamine oxidase inhibitors. Hypersensitivity.

Precautions This product may cause drowsiness; patients should be advised not to drive or operate machinery if affected.

It is dangerous to exceed the stated dose.

Side-effects While significant sympathomimetic side-effects have not been reported, an occasional sensitive patient may experience symptoms characteristic of this class of medicine. Nausea and other gastro-intestinal upsets have been reported occasionally.

Overdosage Signs and symptoms of overdosage include salivation, diuresis, dryness of the mouth, excitement, hypertension, dilated pupils, convulsions, insomnia and tachycardia. Treatment may include emetics gastric lavage, and barbiturates. The patient should be kept cool and quiet.

Pharmaceutical precautions Avoid extremes of temperature.

Legal category POM.

Package quantities Amber glass bottles of 125 ml and 500 ml.

Further information Nil.

Product licence number 0027/5014.

PEXID*

Presentation White, round, flat-faced, bevelled edge tablets. There is a concentric circle 'M' design and on the other side a scored bisect line. Each tablet contains 100 mg of perhexiline maleate.

Uses Pexid is indicated to reduce the frequency of moderate to severe attacks of angina pectoris in patients with coronary artery disease. It is not intended for the treatment of the acute attack. Pexid may be valuable even in patients who do not respond adequately to therapy with other anti-anginal drugs. Sublingual nitroglycerin should be used concomitantly as necessary, for the acute anginal episode if it occurs.

Pexid is also indicated for the management of ventricular extra-systoles in patients with coronary artery disease. It has been proven effective in the elimination or reduction of the extra-systoles, and in the prevention of their recurrence. Until its safety and efficacy have been demonstrated in the acute phase following a myocardial infarction, Pexid should not be used to treat arrhythmias which occur during this period.

Dosage and administration The usual dosage at the beginning of treatment is 100–200 mg per day which may be given in two divided doses. This dosage is to be adjusted progressively up or down at 2 or 4 week intervals based on the results obtained.

It is generally advised not to administer more than 300 mg a day but in certain patients it has been necessary to use 400 mg daily.

The maintenance dose must be the minimum dose which is effective and well-tolerated.

Contra-indications Pexid is contra-indicated in patients with impaired hepatic or renal function and in patients with a known hypersensitivity to the drug.

Precautions During the administration of Pexid, patients must be regularly examined, especially for the appearance of the signs or symptoms described below.

The following clinical and laboratory observations are particularly recommended before and during treatment:

1. Tests for signs and symptoms of peripheral neuropathy, such as paresthesiae, muscle weakness, etc. If the patient complains of visual disturbances, during treatment with Pexid, a complete ophthalmological investigation must be undertaken.
2. Observation for clinical signs of hepatic involvement (weakness, loss of appetite, loss of weight).
3. Determination of serum enzymes (SGPT, SGOT, alkaline phosphatase, LDH) and bilirubin.
4. Determination of blood glucose.
5. Determination of weight.
6. Fundoscopy and tests of visual acuity.

If such medical monitoring proves impractical, Pexid should not be prescribed. Treatment with Pexid should be discontinued in the following instances:

1. Appearance of peripheral neuropathy papilloedema, retinal haemorrhage, or impairment of vision.
2. Appearance of clinical signs of hepatic disease.
3. Persistent elevations in serum enzymes or abnormalities of specific liver function tests.

4. Persistent or marked hypoglycaemia.
5. Excessive weight loss.
6. Other serious side-effects.

Although animal reproductive studies have not indicated adverse effects, Pexid, like most medications, should not be used during the first trimester of pregnancy or during lactation unless, in the opinion of the physician, the potential benefits outweigh the potential risks.

The use of Pexid during the acute phase of myocardial infarction (the period during which clinical and laboratory findings are not stable) has not been established.

Because reported side-effects such as dizziness, lightheadedness and gait disorders may be related to Pexid administration and could be accompanied by syncope or falling, patients with such symptoms should be cautioned about activities such as driving or operating machinery. These symptoms disappear with the cessation of treatment. In many cases, a decrease of the daily dose may cause the side-effects to lessen or disappear.

Pexid should be administered with caution to patients with diabetes.

The effects of Pexid on premature ventricular contractions are consistent with its action on the intraventricular conduction system. Its effects on the same system may also have the potential of producing or aggravating ventricular conduction disturbances.

Pexid has been prescribed with the following medications: nitroglycerin, anticoagulants, digitalis, diuretics, hypolipemics, antihypertensives, tranquilisers and other products.

The safety of concomitant administration with the above products has not yet been established, with the exception of nitroglycerin used in controlled clinical experiments.

In view of the fact that hypoglycaemia has been reported in association with the administration of Pexid, special attention must be paid in the case of concomitant administration of products which could provoke hypoglycaemia, such as antidiabetics and beta-blockers.

In cases where Pexid is discontinued, and another therapy substituted, account must be taken of the half-life of the compound.

Pexid administered orally is rapidly absorbed. It is principally metabolised through hepatic hydroxylation, but the liver has a limited capacity for biotransformation. The metabolites, partially in conjugated form, are eliminated in the urine and faeces. The elimination half-life is in general, two to six days, but may surpass 30 days in certain cases.

Side-effects Adverse reactions may occur in the initial weeks of treatment or the onset may be delayed. Side-effects may be transient and may disappear spontaneously in two to four weeks. More often, they recede only after the dosage is reduced, but sometimes treatment must be discontinued. In general, the appearance and severity of adverse reactions seem to be dose-dependent.

Reported most often are dizziness or a 'drunken' sensation, gait disorders, unsteadiness, as well as nausea, vomiting, headache, anorexia and moderate weight loss (2 to 4 kg).

Frequently reported are moderate and generally transient elevations of serum enzymes (SGOT, SGPT, alkaline phosphatase, LDH) and bilirubin. Increases in total lipids and triglycerides, moderate hypoglycaemia and alterations of the ECG (slight depression of the T-wave and prolongation of the Q-T interval) have also been noted.

Less frequently reported are: profound weakness,

nervousness, lassitude, insomnia, tremors, paraesthesiae, syncope, impaired hearing, genitourinary disorders, changes in libido, flushing or sweating, rash or urticaria.

Rarely reported and not necessarily drug related are: diplopia, visual disturbances, transient loss of vision, papilloedema in the absence of peripheral neuropathy, abdominal pain, extra-pyramidal syndromes, epileptiform seizures, pulmonary alveolitis, autonomic neuropathy, proximal myopathy and jaundice. Delayed nerve conduction velocities have been reported in patients with and without clinical evidence of neuropathy.

Occasionally, more serious side-effects have been reported in patients being treated with Pexid:

Sensori-motor polyradiculoneuritis which can affect the four limbs and which may be accompanied by papillitis and papilloedema and an increase in the protein (albumin) content of the cerebrospinal fluid. This polyradiculoneuritis first appears as paraesthesiae of the extremities, and/or weakness of the legs with difficulty in walking. In addition, signs and symptoms thought to be manifestations of benign intracranial hypertension (pseudotumour cerebri) have been reported. These include papilloedema, decreased visual acuity, retinal haemorrhages and exudates and, in rare instances, sixth nerve palsy, optic atrophy and loss of vision. In such instances Pexid must be discontinued promptly and appropriate treatment instituted.

Polyradiculoneuritis, hypoglycaemia and weight loss usually regress with suspension of treatment with Pexid.

Hepatic disorders, including some cases similar in type to subacute alcoholic hepatitis, which have occasionally shown cirrhotic changes. The state of the liver before treatment with Pexid and the influence of concomitant therapy or aetiological factors such as alcohol and viral hepatitis are not known.

In rare cases, hepatic damage or hypoglycaemia have led to the death of the patient. Intracellular lipid inclusions have been observed by electron microscopy in tissue specimens from some patients with neuropathy and/or hepatitis.

Overdosage Gastric lavage, emetics, and Universal Antidote (activated charcoal 2 parts, tannic acid 1 part, magnesium oxide 1 part) are recommended.

Pharmaceutical precautions Pexid tablets should be protected from light and kept in a cool dry place.

Legal category POM.

Package quantities Blister strips of 25 in cartons of 50 tablets.

Further information Nil.

Product licence number 4425/0019.

RIFADIN*

Presentation Rifadin capsules (blue and red) marked 'Lepetit', containing 150 mg rifampicin.

Rifadin capsules (red) marked 'Lepetit', containing 300 mg rifampicin.

Rifadin syrup (raspberry colour and flavour), containing 100 mg rifampicin in each 5 ml.

Uses Rifadin, used in combination with other active antituberculosis drugs, is indicated in the treatment of all forms of tuberculosis, including fresh, advanced, chronic and drug-resistant cases. It is also effective against many atypical strains of mycobacteria. Rifadin is active *in vitro* at low concentrations against Gram-positive organisms

and at higher concentrations against Gram-negative organisms.

Dosage and administration The daily dose of Rifadin, calculated from the patient's body weight, should preferably be taken before meals to ensure rapid and complete absorption. Rifadin should be given with other effective antituberculosis drugs to prevent the possible emergence of rifampicin-resistant strains of mycobacteria.

Adults: A single, daily oral dose of 600 mg has been found in clinical practice to be well tolerated, effective and safe for adult patients. A more precise daily dosage can be calculated on the basis of 8–12 mg/kg body weight. Doses towards the lower end of this scale are recommended for frail and elderly patients. A daily dose of 8 mg/kg body weight should not be exceeded in patients with impaired liver function.

Children: In children, oral doses of up to 20 mg/kg body weight daily are recommended, although a total daily dose should not usually exceed 600 mg.

Contra-indications, warnings, etc

Contra-indications: Rifadin is contra-indicated in the presence of jaundice. Rifadin is contra-indicated during the first trimester of pregnancy, and should only be used during the second and third trimesters after careful appraisal of all aspects of the patient's condition. Rifadin is contra-indicated in patients who are hypersensitive to the rifamycins.

Precautions: Patients with impaired liver function should be given Rifadin only in cases of necessity, and then with caution and under close medical supervision. Lower doses of rifampicin and monitoring of liver function are recommended in these cases. In patients with impaired liver function, elderly patients, malnourished patients, and, possibly, children under two years of age, caution is particularly recommended when instituting therapeutic regimens in which isoniazid is to be used concurrently with Rifadin. It is rarely necessary, in the absence of clinical findings, to increase the frequency of performing routine liver function tests in patients with normal pretreatment liver function. An isolated report showing a moderate rise in the serum bilirubin and/or transaminase level is not usually in itself an indication for interrupting treatment; rather the decision should be made after repeating the tests, noting the trends in the levels, and considering them in conjunction with the patient's clinical condition. It has been possible in many patients in whom alterations to liver function prompted interruption of Rifadin therapy, to reinstate the drug without ill-effect.

If *p*-aminosalicylic acid and Rifadin are both included in the treatment regimen, they should be given not less than eight hours apart to ensure satisfactory blood levels.

Rifadin has been shown in animals and man to have liver enzyme inducing properties and may reduce the activity of anticoagulants, corticosteroids, digitalis preparations, oral contraceptives and oral hypoglycaemic agents. It may be necessary to adjust the dosage of these drugs if they are given concurrently with Rifadin, particularly when it is initiated or withdrawn.

Patients on oral contraceptives should be advised to use alternative, non-hormonal methods of birth control during Rifadin therapy.

Side-effects: Apart from occasional gastric intolerance and hypersensitivity reactions, Rifadin is generally very well tolerated and accepted by patients.

Eosinophilia and leucopenia have been reported to occur in a small percentage of patients but no clinical significance has been attributed to this. In some patients hyperbilirubinaemia, resulting from competition between Rifadin and bilirubin for the excretory pathways of the liver at cellular level, can occur in the early days of treatment. A rise in serum transaminase levels may also occur at this time but a return to pretreatment levels is to be expected as the liver adjusts to the metabolic handling of Rifadin. Cases of hepatocellular damage associated with antituberculosis drug regimens that have included rifampicin have been reported. The available evidence suggests that the incidence and severity of this may be higher in those patients with pre-existing liver impairment who are simultaneously receiving isoniazid. However, animal toxicology studies and pharmacokinetic investigations in humans have failed to disclose any significant or consistent interaction between the two substances. Side-effects, probably of immunological/allergic origin, such as fever, skin rashes, occasional renal dysfunction and haematological abnormalities (e.g. thrombocytopenia) have been reported, particularly in connection with intermittent, interrupted or repeated treatment.

Occasional disturbances of the menstrual cycle have been reported in women receiving long term antituberculosis chemotherapy using regimens containing rifampicin. The effectiveness of oral contraceptives may also be reduced.

Rifadin may produce a reddish discolouration of the urine, sputum and tears. The patient should be forewarned of this.

Overdosage: In cases of overdosage with Rifadin, gastric lavage should be performed as soon as possible. Intensive supportive measures should be instituted and individual symptoms treated as they arise. Although it has not been observed in man, animal studies suggest a possible neuro-depressant action associated with very high doses of Rifadin.

Pharmaceutical precautions Rifadin capsules have a shelf life of four years when stored below 25°C. Rifadin Syrup has a shelf life of three years. Rifadin syrup should not be diluted. It should be dispensed in clear or amber glass bottles.

If it proves necessary to open a blister pack, Rifadin capsules should be dispensed in amber glass or plastic containers. Protect from moisture.

Legal category POM.

Packaging quantities

Rifadin capsules 150 mg Bottles of 100 capsules.

Rifadin capsules 300 mg Bottles of 100 capsules.

Rifadin syrup 100 mg/5 ml Bottles of 120 ml.

Further information An oral dose of 450–600 mg Rifadin produces therapeutically effective levels in the blood, with the peak concentrations being observed approximately 2 hours after administration. There is good distribution of Rifadin into body tissues and fluids, including lung, bone, lymph nodes and inflammatory exudates. Rifadin is excreted mainly in the bile and urine, and high concentrations are reached in both these fluids. No cross resistance has been shown between Rifadin and other antituberculosis drugs. Rifadin is compatible with other antituberculosis drugs and has been shown clinically to be particularly effective in combination with isoniazid and ethambutol.

RIFINAH*

Presentation *Rifinah 300*: orange, capsule-shaped tablets containing 300 mg rifampicin and 150 mg isoniazid – marked RH 300.

Rifinah 150: cyclamen, round biconvex tablets containing 150 mg rifampicin and 100 mg isoniazid – marked RH 150.

Uses Rifinah 300 and Rifinah 150 are indicated in the treatment of all forms of tuberculosis, including fresh, advanced and chronic cases.

Dosage and administration The daily dose of Rifinah 300 or Rifinah 150 should preferably be taken before meals to ensure rapid and complete absorption. Another antituberculosis drug may be given concurrently until the susceptibility of the infecting organism to rifampicin and isoniazid has been confirmed.

Adults: For patients of 50 kg (8 stone) and over.

Two Rifinah 300 tablets to be taken in a single daily dose before a meal. The patient receives 600 mg rifampicin and 300 mg isoniazid.

For patients of less than 50 kg (8 stone):

Three Rifinah 150 tablets to be taken in a single daily dose before a meal. The patient receives 450 mg rifampicin and 300 mg isoniazid.

Contra-indications, warnings, etc

Contra-indications: Rifinah 300 and Rifinah 150 are contra-indicated in the presence of jaundice. Rifinah 300 and Rifinah 150 are contra-indicated during the first trimester of pregnancy and should only be used during the second and third trimesters after careful appraisal of all aspects of the patient's condition. Rifinah 300 and Rifinah 150 are contra-indicated in patients who are hypersensitive to the rifamycins or isoniazid.

Precautions: Patients with impaired liver function should be given Rifinah 300 or Rifinah 150 only in cases of necessity and then with caution and under close medical supervision. Careful monitoring of liver function is recommended for these patients. Similar care should be exercised in elderly patients, malnourished patients, and children under two years of age. It is rarely necessary in the absence of clinical findings to increase the frequency of performing routine liver function tests in patients with normal pretreatment liver function. An isolated report showing a moderate rise in the serum bilirubin and/or transaminase level is not usually in itself an indication for interrupting treatment; rather the decision should be made after repeating the tests, noting the trends in the levels, and considering them in conjunction with the patient's clinical condition. Experience has shown that in many cases these changes are transient and usually revert towards normal pretreatment levels in about two weeks, even when the treatment is continued. Where alterations in liver function cause treatment with Rifinah 300 or Rifinah 150 to be interrupted it may be possible after an interval to reinstate the drug without ill-effect. If *p*-aminosalicylic acid and Rifinah 300 or Rifinah 150 are both included in the treatment regimen they should be given not less than eight hours apart to ensure satisfactory blood levels. Rifinah has been shown in animals and man to have liver enzyme inducing properties and may reduce the activity of anticoagulants, corticosteroids, digitalis preparations, oral contraceptives and

oral hypoglycaemic agents. It may be necessary to adjust the dosage of these drugs if they are given concurrently with Rifinah, particularly when it is initiated or withdrawn.

Patients on oral contraceptives should be advised to use alternative, non-hormonal methods of birth control during Rifinah therapy.

Side-effects: Rifampicin and isoniazid, the component drugs in Rifinah 300 and Rifinah 150, are well tolerated at the recommended dosage. Occasional gastro-intestinal disturbances and hypersensitivity reactions may occur. Polyneuritis associated with isoniazid, presenting as paraesthesia, muscle weakness, loss of tendon reflexes etc., is unlikely to be associated with the 300 mg of isoniazid contained in the daily adult dose of Rifinah 300 and Rifinah 150. Various haematological disturbances have been associated with isoniazid, including eosinophilia, agranulocytosis and anaemia.

Eosinophilia and leucopenia have been reported to occur in a small percentage of patients treated with rifampicin but no clinical significance has been attached to this. In some patients hyperbilirubinaemia, resulting from competition between rifampicin and bilirubin for the excretory pathways of the liver at cellular level, can occur in the early days of treatment. A rise in serum transaminase levels may also occur at this time but a return to pretreatment levels is to be expected as the liver adjusts to the metabolic handling of rifampicin. Cases of hepato-cellular damage associated with anti-tuberculosis drug regimens that have included rifampicin and isoniazid have been reported. The available evidence suggests that the incidence and severity of this may be higher in those patients with pre-existing liver impairment. However, animal toxicology studies and pharmacokinetic investigations in humans have failed to disclose any significant or consistent interaction between the two substances.

Side-effects associated with rifampicin, probably of immunological/allergic origin, such as fever, skin rashes, occasional renal dysfunction and haematological abnormalities (e.g. thrombocytopenia) have been reported, particularly in connection with intermittent, interrupted or repeated treatment. Occasional disturbances of the menstrual cycle have been reported in women receiving long term anti-tuberculosis chemotherapy using regimens containing rifampicin. The effectiveness of oral contraceptives may also be reduced.

The rifampicin in Rifinah 300 and Rifinah 150 may produce a reddish discolouration of the urine, sputum and tears and the patient should be forewarned of this.

High doses of isoniazid can cause convulsions. Although this is unlikely to happen with the recommended dose of Rifinah 300 or Rifinah 150, the possibility that the frequency of fits may be increased in patients with epilepsy should be borne in mind. Symptoms due to isoniazid occur more frequently in slow inactivators of the drug.

Overdosage: In cases of overdosage with Rifinah 300 or Rifinah 150, gastric lavage should be performed as soon as possible. Intensive supportive measures should be instituted and individual symptoms treated as they arise. Parenteral pyridoxine (Vitamin B₆) should be given. Symptoms are more likely to be related to isoniazid, including coma, respiratory distress, hyperglycaemia and metabolic ketoacidosis.

Although it has not been observed in man, animal studies suggest a possible neuro-depressant action associated with very high doses of rifampicin.

Pharmaceutical precautions Rifinah 300 and Rifi-

nah 150 tablets have a shelf life of four years when stored below 25°C.

If it proves necessary to open a blister pack, Rifinah 300 and Rifinah 150 should be dispensed in amber glass or plastic containers. Protect from moisture.

Legal category POM.

Package quantities

Rifinah 300 4 weeks calendar packs – 56 tablets
Bottles of 100 tablets.
Rifinah 150 4 weeks calendar pack – 84 tablets
Bottles of 100 tablets.

Further information The recommended daily dose of Rifinah 300 or Rifinah 150 produces therapeutically effective blood levels of rifampicin and isoniazid, two of the most powerful anti-tuberculosis drugs. Serum concentrations and the biological half-life of the two component drugs do not differ significantly from values obtained when the drugs are given alone.

SYNDOL®

Presentation Syndol Tablets are yellow, round, flat-faced, bevelled-edge tablets. On one side there is an incised 'S' design and on the other a scored bisect line. Each tablet contains:

Paracetamol BP	450 mg
Codeine Phosphate BP	10 mg
Decapryn® (Doxylamine Succinate USNF)	5 mg
Caffeine BP	30 mg

Uses For the treatment of mild to moderate pain and as an antipyretic. Syndol is recommended for the symptomatic relief of headache, including muscle-contraction or tension headache, migraine, neuralgia, toothache, sore throat, dysmenorrhoea, muscular and rheumatic aches and pains, and for post-operative analgesia following surgical or dental procedures.

Dosage and administration *Adults and children over 12 years:* 1 or 2 tablets every four or six hours as needed for relief. Total dosage over a 24-hour period should not normally exceed 8 tablets.

Not recommended for children under 12 years.

Contra-indications, warnings, etc Idiosyncrasy to any of the ingredients.

Precautions: May cause drowsiness; if affected, patients should be advised not to drive or operate machinery.

Side-effects: Doxylamine succinate may cause drowsiness or dizziness in some patients. Mild constipation may occur associated with the codeine component of Syndol. Agranulocytosis is a very rare complication of treatment with paracetamol.

Overdosage: Treat symptomatically as for paracetamol and codeine.

Pharmaceutical precautions None.

Legal category POM.

Package quantities Blister strips of 10 in packs of 50 tablets.

Further information Nil.

Product licence number 4425/0018.

Product licence number

Tace Tablets 0027/5015

TACE*

Presentation Tace Tablets are off-white, round, convex tablets, scored one side and stamped 'T' in two concentric circles on the reverse. Each tablet contains Chlorotrianisene BP 24 mg.

Uses Tace is an oestrogen indicated for:

1. *Oestrogen deficiency states* – primarily the *menopausal syndrome* (when periods have stopped).
2. *Postpartum breast engorgement* – for prevention and treatment of *painful breast engorgement* in patients who do not nurse their baby.
3. *Prostatic cancer* – for palliative control.

Dosage and administration

1. *Oestrogen deficiency states* (when periods have stopped). One tablet daily for a 30-day course. Often 1 course is sufficient, but in severe cases 2 or more courses, repeated as needed, may be required.
2. *Postpartum breast engorgement* – 2 tablets three times a day for four days. Begin treatment as soon after delivery as possible for best results.
3. *Prostatic cancer* – for palliative control. One tablet daily.

Contra-indications Patients with, or suspected of having, oestrogen-dependent carcinoma of the breast or genital organs.

Warning: Prolonged exposure to unopposed oestrogens may increase the risk of the development of endometrial carcinoma.

Side-effects Tace is well tolerated and side-effects are uncommon when it is used in the recommended dosage. Prolonged continuous administration can lead to endometrial hyperplasia and break-through bleeding. Withdrawal bleeding has also been reported. Gynaecomastia (seldom painful) and reduced potency have occurred in the male. Gastro-intestinal side-effects (nausea and vomiting), often associated with oestrogen therapy, have only occasionally been described with Tace. Although oedema is rare, caution should be exercised when oestrogens must be given to patients whose renal function reserve is low, such as those with borderline cardiac decompensation. Urticarial and other cutaneous reactions have occasionally been reported with Tace.

Overdosage Signs and symptoms of overdosage in the *female* include nausea and vomiting, headache, abdominal distress, anorexia, fluid retention, uterine bleeding; and in the *male*, gynaecomastia, loss of libido and atrophy of sexual organs. Treatment of acute overdosage should include supportive therapy, gastric lavage, diuretics (as indicated) and progestin therapy for uterine bleeding.

Pharmaceutical precautions None.

Legal category POM.

Package quantities Amber glass bottles of 50.

Further information Nil.

TENUATE*

Presentation Tenuate Dospan* Tablets are white, flat, bevelled, oblong tablets, scored on one side and stamped 'Merrell' on the other side. Each contains diethylpropion hydrochloride BP 75 mg in a hydrophilic colloid gum designed to release the ingredient over a 10-hour period.

Uses Anorectic agent indicated for overweight and obesity.

Dosage and administration *Adults and children over 12 years:* One 75 mg tablet swallowed whole in mid-morning.

Not recommended for children under 12 years.

Current medical opinion supports intermittent use of an appetite suppressant. Courses of Tenuate may be given over periods of six to eight weeks, with intervening periods of one month without treatment. Tenuate should be discontinued when patients stop losing weight.

Contra-indications Diethylpropion hydrochloride should not be given concurrently with monoamine oxidase inhibitors, nor should it be given to patients hypersensitive to diethylpropion hydrochloride or to emotionally unstable individuals who are known to be susceptible to drug abuse.

Precautions Although diethylpropion hydrochloride is generally safer than the amphetamines, it should be used with caution in severe hypertension and severe cardiovascular disease. Although rat and human reproductive studies have not indicated adverse effects, diethylpropion hydrochloride, like all medicines, should not be used during the first trimester of pregnancy, unless, in the opinion of the prescribing doctor, the potential benefits outweigh the potential risks.

Since the introduction of diethylpropion in 1958 it has been used by more than 33,000,000 patients. Against this background of extensive clinical use, reports of abuse have been extremely uncommon. Most of the subjects had previously abused other drugs such as amphetamine and phenmetrazine and many were described as having unstable personalities. Addicts have reported relatively little euphoria, and dissatisfaction in the few cases where diethylpropion was administered intravenously. Other abusers after oral administration of diethylpropion have shown marked anxiety and agitation as the effects wore off. After diethylpropion had been taken for 24–72 hours, additional doses did not produce euphoria but agitation and anxiety instead. Hallucinations occurred rarely following relatively high doses of the drug.

Several cases of toxic psychosis have been reported following the excessive use of diethylpropion and a very small number have been reported in which the recommended dose appears not to have been exceeded. The psychosis was temporary and cleared up after the drug was discontinued.

Side-effects Rarely severe enough to require discontinuation of therapy, side-effects associated with diethylpropion hydrochloride have been reported to occur in relatively low incidence. These have included insomnia, nervousness, dryness of the mouth, depressive reactions, headache, tachycardia, constipation, and

allergic rashes. Infrequent occurrences of nausea and vomiting have been noted, but diarrhoea is exceedingly rare.

Overdosage A few unsuccessful suicidal attempts by deliberate overdosage of diethylpropion hydrochloride have been reported. Dosage ranged from 450 to 2,250 mg. Transient sequelae included semicoma or coma, lethargy, increased irritability and nausea.

Accidental overdosage has been reported in several children, 6 months to 3½ years old. Known doses ranged from 50 to 1,100 mg. The most frequent effects were motor hyperactivity, excitability, tachycardia, rapid respiration, pupillary dilatation, and flushing. Treatment usually consisted of gastric lavage, sedation and close observation. Recovery occurred in all patients except one, in whom treatment with a large intravenous dose of sodium amobarbital was implicated.

Pharmaceutical precautions Store in a cool dry place.

Legal category POM.

Package quantities Tenuate Dospan Tablets are in blister strips of 10 in cartons of 100.

Further information Nil.

Product licence number

TRILUDAN* ▼

Presentation White, round, flat faced, bevel edge tablets with 'M' in two concentric circles on one side and a scored bisect line with the code 084 on the other. Each tablet contains 60 mg terfenadine.

Uses Triludan is an antihistamine which is indicated for the symptomatic relief of hay fever, allergic rhinitis and allergic skin conditions.

Dosage and administration *Adults and children over 12 years:* one tablet twice daily.

Children aged 6–12 years: ½ tablet twice daily.

Contra-indications, warnings, etc None known.

Precautions: Although animal reproductive studies have not indicated adverse effects, Triludan, like most medications, should not be used during pregnancy nor during lactation unless, in the opinion of the physician, the potential benefits outweigh any possible risk.

Side-effects: In clinical trials of one or more weeks duration at therapeutic doses drowsiness, usually slight, has been observed, generally with an incidence equal to or less than that observed with placebo in the same trials. Headache, sweating and mild gastro-intestinal disturbances have also been infrequently reported.

Overdosage: There is no experience of overdosage (doses of 600 mg daily have been tolerated with only minor symptoms). Gastric lavage and symptomatic management are advised.

Pharmaceutical precautions None.

Legal category POM.

Package quantities Blister strips of 10 in cartons of 50 tablets.

Further information Nil.

Product licence number 4425/0024.

ATTENUVAX* ▼

Presentation Lyophilised powder for injection. When reconstituted, each dose of Attenuvax Injection contains not less than the equivalent of 1,000 TCID₅₀ (tissue culture infectious doses) of measles virus vaccine expressed in terms of the assigned titre of the FDA Reference Measles Virus. Attenuvax is a more attenuated line of measles virus derived from Enders' attenuated Edmonston strain.

Uses For general immunisation against measles.

Children: The Department of Health recommends that children 12 months of age or older be vaccinated against measles. (Please refer to 'Contra-indications'.)

Attenuvax given immediately after exposure to natural measles may provide some protection. If, however, the vaccine is given a few days before exposure, substantial protection may be provided.

Dosage and administration After suitably cleansing the injection site, the total volume of reconstituted vaccine should be injected subcutaneously, preferably into the outer aspect of the arm. Attenuvax must not be given intravenously.

The dose of vaccine is the same for all patients.

Warning: A sterile syringe and Adrenaline Injection BP (1:1,000) should be ready for immediate use should an anaphylactoid reaction occur.

Contra-indications, warnings, etc *Contra-indications:* Infants below 15 months of age may fail to respond to the vaccine due to the presence of residual measles antibody of maternal origin; the younger the infant, the lower the chance of seroconversion. Children below the age of 12 months should not normally be given Attenuvax unless they are at special risk. Where immunisation below the age of 12 months is deemed necessary, a second dose should be given after the child has reached 15 months of age.

Any active or suspected infection is reason for delaying vaccination. Active untreated tuberculosis. Malignant disease.

Attenuvax should not be given to those with impaired immunoresponsiveness occurring naturally, or as a result of treatment with steroids, radiotherapy, cytotoxic drugs or other agents. This contra-indication does not apply to patients receiving corticosteroids for replacement therapy, e.g. Addison's disease.

Hypersensitivity to neomycin (each dose of reconstituted vaccine contains approximately 25 mcg of neomycin).

Hypersensitivity to eggs, chicken or chicken feathers: Attenuvax is essentially devoid of potentially allergenic substances derived from host tissues (chick embryo). However, since this vaccine is propagated in cell cultures of chick embryos, the benefits of its use in patients hypersensitive to eggs, chicken or chicken feathers must be weighed against the potential risks of hypersensitivity reactions. Significantly, children with known allergies

experienced no reactions other than those already seen in non-allergic children.

Pregnancy: Do not give Attenuvax to pregnant women, because the possible effects of the vaccine on foetal development are unknown at this time. It is recommended that pregnancy at the time of vaccination be ruled out, and that the possibility of pregnancy occurring in the three months following vaccination must be prevented by medically acceptable methods.

Warnings and adverse effects: Attenuvax is for subcutaneous injection only; it must not be given intravenously.

Attenuvax may be given simultaneously with monovalent or trivalent poliovirus vaccine, live, oral, with Meruvax* II (Rubella Virus Vaccine, Live) and/or Mumpsax* (Mumps Virus Vaccine, Live). Attenuvax should not be given less than one month before or after immunisation with other live virus vaccines.

Children with a history of convulsions, or with parental history of epilepsy (non-traumatic) are considered to be at greater risk of convulsions.

In these cases, it is recognised that the simultaneous administration of normal immune globulin (0.6 mg/lb [1.3 mg/kg] bodyweight) could be beneficial, although it should be recognised that the administration of immunoglobulin might increase the proportion of failures to immune.

It may therefore be necessary to undertake a serological test to determine whether immunisation has been successful.

Attenuvax should not normally be given within three months of a transfusion with blood, or human plasma, or treatment with human immunoglobulin. If any of these substances have been used near to the time of vaccination, a test for the presence of measles antibody should be made at a later date.

It has been reported that live attenuated measles virus vaccine may result in a temporary depression of tuberculin skin sensitivity. If a tuberculin test is to be done, it should be administered either before or with Attenuvax.

Children under treatment for tuberculosis have not experienced exacerbation of the disease when immunised with live measles virus vaccine, and no studies have been reported on the effect of measles virus vaccines on untreated tuberculous children.

The occurrence of thrombocytopenia and purpura associated with live virus measles vaccines has been extremely rare.

Because the vaccine is slightly acidic (pH 6.2-6.6), patients may complain of burning and/or stinging at the injection site for a short time.

Moderate fever and rash may occur during the month after vaccination. Rarely, high fever or local reaction may occur. Children developing fever may, on rare occasions, exhibit febrile convulsions.

There have been isolated reports of ocular palsies and Guillain-Barre syndrome occurring after immunisation with vaccines containing live attenuated measles virus. The ocular palsies have occurred approximately 3-24

days following vaccination. No definite causal relationship has been established between either of these events and vaccination.

There have been reports of subacute sclerosing panencephalitis (SSPE) in children who did not have a history of natural measles but did receive measles vaccine. Some of these cases may have resulted from unrecognised measles in the first year of life or possibly from the measles vaccination. Based on estimated nationwide measles vaccine distribution in the USA, the association of SSPE cases to measles vaccination is about one case per million vaccine doses distributed. This is far less than the association with natural measles: 5–10 cases of SSPE per million cases of measles.

Local reactions characterised by marked swelling, redness and vesiculation at the injection site of attenuated live virus measles vaccines have occurred in children who have previously received killed measles vaccine. Allergic reactions such as wheal and flare at the injection site have been reported.

Treatment of overdose: Not applicable.

Pharmaceutical precautions Prior to reconstitution, the vaccine should be shipped and stored between 2°–8°C. *Protect from light.*

Studies have shown that the vaccine contains a minimum of 1,000 TCID₅₀ per dose after storage at any one of the following temperatures for the stated time period:

<i>Dried Vaccine</i>	<i>Retention of Potency</i>
<i>Storage Temperature</i>	<i>1,000 TCID₅₀ per dose</i>
2°–8°C	2 years
20°–25°C	4 months
37°C	2 weeks
45°C	6 days

The vaccine should be reconstituted using only the diluent provided, and used immediately after reconstitution.

Colour: The vaccine when reconstituted is yellow. It is acceptable for use only when clear.

Legal category POM.

Package quantities A single-dose vial of lyophilised, vaccine, packed with an ampoule containing diluent.

Further information Experience from more than 80 million doses of all live measles vaccines given in the USA through 1975 indicates that significant central nervous system reactions such as encephalitis and encephalopathy, occurring within 30 days after vaccination, have been temporally associated with measles vaccine approximately once for every million doses. In no case has it been shown that reactions were actually caused by vaccine. The risk of such serious neurological disorders following live measles virus vaccine administration remains far less than that for encephalitis and encephalopathy caused by natural measles (one per thousand reported cases).

A study suggests that the overall effect of measles vaccine has been to protect against SSPE by preventing measles with its inherent higher risk of SSPE.

Product licence number 0025/0070.

DOLOBID®

Presentation Peach-coloured, capsule-shaped, film-coated tablets, marked 'DOLOBID', containing 250 mg

diflunisal; and orange-coloured, film-coated tablets, marked 'DOLOBID', containing 500 mg diflunisal.

Uses Dolobid is indicated for the relief of pain.

Dolobid is also indicated in the relief of pain and inflammation associated with osteoarthritis and rheumatoid arthritis.

Dosage and administration The initial dosage is 500 mg given twice daily. For longer-term therapy, dosage can be adjusted to 250 mg or 500 mg given twice daily. Dosage should be adjusted to the nature and intensity of the pain being treated and should be given twice a day. Even if the initial dose is taken in the afternoon, a second dose should be taken at bedtime. Tablets should be swallowed whole, not crushed or chewed. The highest dose studied in patients was 1500 mg daily.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to the drug.

In patients who have previously experienced acute asthmatic attacks precipitated by aspirin or non-steroidal anti-inflammatory agents.

The drug should not be administered to patients with active gastro-intestinal bleeding.

The use of Dolobid should be avoided in patients with active peptic ulcer.

Dolobid should not be given to pregnant women, since the safety for this use has not been established. Nursing mothers should not take Dolobid, or should stop nursing.

Precautions: Dolobid should be used with caution in patients having a history of gastro-intestinal haemorrhage or ulcers.

Use with caution in patients receiving anticoagulant therapy since concomitant administration may prolong the prothrombin time.

Co-administration of aluminium hydroxide suspension significantly decreases the absorption of Dolobid by approximately 40%.

The dosage of Dolobid may need to be reduced in patients with renal functional impairment since the major route of excretion is via the kidney. In patients with severe renal impairment, the drug should not be used.

No evidence of renal toxicity has been seen at therapeutic dose levels in man. In rats and dogs, high oral doses of diflunisal (50–200 mg/kg/day) as with aspirin, produced similar pathological changes (gastro-intestinal ulceration and renal papillary oedema). These dosages are approximately 3 to 12 times the maximum dosages recommended in man.

Transient elevations of bilirubin and other routine liver function tests have occurred rarely. The clinical significance of these transient elevations has not been determined.

Since paediatric indications and dosage have not yet been established, Dolobid should not be given to children.

Side-effects: Dolobid is generally well tolerated.

Those side-effects experienced are usually mild, the most common being related to the upper gastro-intestinal tract.

Digestive system: Gastric pain, dyspepsia, nausea, and vomiting.

Isolated cases of gastro-intestinal ulcer and bleeding have been reported.

Central nervous system: Vertigo, somnolence, and rarely mild tinnitus, have been reported infrequently.

Skin: Pruritus and rash have been reported rarely. Cross-sensitivity with aspirin was suspected in two patients. A few cases of erythema multiforme, including the Stevens-Johnson syndrome, have been reported. A causal relationship with Dolobid has not been established.

Treatment of overdosage:

The initial plasma half-life following single oral doses of diflunisal seems to be dose dependent, ranging from approximately 7.5 hours for a 250 mg dose to 11 hours for a 500 mg dose.

When an acute overdose is taken, the stomach should be emptied by vomiting or lavage, though little drug will likely be recovered if more than an hour has elapsed since ingestion.

To facilitate urinary elimination of the drug, attempt to maintain renal function. Because of the high degree of protein binding, haemodialysis is not recommended.

Pharmaceutical precautions Store in a cool place, protected from light.

Legal category POM.

Package quantities Dolobid 250 mg tablets are supplied in packs of 50, 100 and 1,000 tablets; the 500 mg tablets in packs of 100.

Further information Following a single therapeutic dose, significant relief of pain usually occurs within the first hour. Dolobid has a prolonged duration of action and is therefore administered twice daily.

Dolobid has a dose-related effect on platelet function. In normal volunteers given Dolobid over eight days, 250 mg twice daily had no effect on platelet function and 500 mg twice daily affected platelet function only slightly. However, 1,000 mg twice daily inhibited platelet function. In contrast to acetylsalicylic acid, these effects were reversible.

Bleeding time was unaffected by 250 mg twice daily, slightly increased at 500 mg twice daily, and the greater increase at 1,000 mg twice daily was not statistically significant from placebo.

Faecal blood loss is significantly less following treatment with Dolobid (250 mg b.d.) than that associated with aspirin (600 mg q.i.d.).

500 mg tablet 0025/0146

H-B-VAX* ▼

Presentation Available as 1 ml vials of sterile suspension containing 20 mcg of Hepatitis B surface antigen adsorbed on to alum.

Uses H-B-Vax is indicated for immunisation against infection caused by hepatitis B virus, including all known subtypes.

The incidence of infection varies greatly in different parts of the world, and the vaccination strategy should be adjusted accordingly.

In areas of low prevalence, vaccination should be limited to those who are at increased risk of infection, such individuals would be found among:

Health care personnel: Dentists; physicians and surgeons; nurses and hospital ancillary workers; dental hygienists; laboratory personnel handling blood products from known carriers; health care students, especially those treating known carriers.

Patient and patient contacts: Patients in haemodialysis, haematology and oncology units; patients who need frequent and/or large-volume blood transfusions and clotting factor concentrates; residents and staff of mental institutions; intimate contacts of persons with persistent hepatitis B antigenaemia.

Plasma fractionation workers.

Persons at increased risk due to their sexual practices: Homosexually active males; prostitutes; persons who repeatedly contract sexually transmitted diseases.

Users of illicit injectable drugs.

Those living for prolonged periods in countries where Hepatitis B is endemic.

Dosage and administration H-B-Vax is for intramuscular use only; it must not be given intravenously, subcutaneously or intradermally.

Shake well before use. After thorough agitation H-B-Vax is an opaque, white suspension.

The immunisation regimen consists of three doses of vaccine given intramuscularly.

1st dose: at elected date

2nd dose: 1 month later

3rd dose: 6 months after first dose, as a 'booster'

The volume of dose to be given on each occasion is:

Group	Initial	1 month	6 months
Children 6 months to 10 years	0.5 ml (10 mcg)	0.5 ml (10 mcg)	0.5 ml (10 mcg)
Adults and children over 10 years	1.0 ml (20 mcg)	1.0 ml (20 mcg)	1.0 ml (20 mcg)
Dialysis and immunocompromised	Dose to be determined from ongoing studies		

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to any component of the vaccine.

Warnings: Because of the prolonged incubation period of hepatitis B, infection may be present at the time of vaccination. H-B-Vax may be ineffective in such patients.

Patients with immuno-deficiency or those receiving immuno-suppressive therapy may need larger doses of H-B-Vax.

Although study is still needed to determine the effectiveness of H-B-Vax after infection with hepatitis B, it has been shown that an injection of up to 3 ml of hepatitis B immunoglobulin does not interfere with the action of H-B-Vax injected at a different site.

Precautions: Adrenaline Injection BP (1:1000) should be available for immediate use should an anaphylactoid reaction occur.

Any serious active infection is reason for delaying vaccination unless, in the physician's opinion, this delay might entail even greater risk.

Caution should be exercised in administering H-B-Vax to individuals in whom a febrile or systemic reaction could pose a significant risk such as in patients with a severely compromised cardio-pulmonary status.

Nursing mothers: Because it is not known whether H-B-Vax is excreted in human milk, the physician should exercise caution before vaccinating nursing mothers with H-B-Vax.

Children: The safety and efficacy of H-B-Vax has not been determined in infants under 6 months of age. H-B-Vax is not recommended for infants of this age.

Pregnancy: H-B-Vax is not recommended for pregnant women. Animal reproduction studies have not been

conducted with the vaccine. It is also not known whether H-B-Vax can cause foetal harm when administered to pregnant women, or can affect reproductive capacity.

Adverse reactions: In studies involving over 1,000 adult volunteers, approximately 25% reported some local or systemic complaint. The most commonly occurring reactions are local soreness and erythema at the injection site. Local swelling, warmth, or induration are reported less frequently, and subside within two days of vaccination.

Low grade fever (less than 101°F) occurs occasionally and is usually confined to the 48-hour period following vaccination. Although uncommon, fever over 102°F has been reported.

Systemic complaints including malaise, fatigue, headache, nausea, myalgia, and arthralgia are infrequent and have been limited to the first few days following vaccination. Rash has been reported rarely.

Treatment of overdose: Not applicable.

Pharmaceutical precautions Store unopened and opened vials at 2–8°C (35.6–46.4°F). DO NOT FREEZE. The vaccine is used directly as supplied; no dilution or reconstitution is necessary. Thiomersal in 1:20,000 dilution is present in the vaccine as a preservative.

Legal category POM.

Package quantities One-ml vials of sterile suspension containing vaccine.

Further information The protective efficacy of H-B-Vax has been demonstrated in human populations. In a study involving individuals with a high risk of contracting hepatitis B virus infection, H-B-Vax has been shown to reduce the incidence of infection by over 90%. The vaccine protected against acute hepatitis B, asymptomatic infection, and chronic antigenaemia. There was evidence of immunity (neutralising antibody) in 87% of vaccinated subjects after administration of two doses of the 3-dose vaccine regimen. However, the third dose (booster dose) was necessary for both a high percentage of responses (96%), and long-term protective effect (i.e. vaccine-induced antibody persisting during the entire 24-month follow-up period).

Although the duration of protective effect of H-B-Vax is unknown at present, available data suggest that immunity will last for about 5 years in patients who have received all three doses, after which time a single booster dose of vaccine might be necessary to maintain immunity.

Product licence number 0025/0164.

INDOCID*

Presentation Ivory, opaque capsules containing 25 mg or 50 mg indomethacin BP, marked 'INDOCID 25' and 'INDOCID 50' respectively.

Ivory, opaque-based, transparent-headed capsules carrying white and blue pellets containing 75 mg indomethacin BP in sustained-release form, marked 'INDOCID R 693'.

A fruit-flavoured suspension containing in each 5 ml, 25 mg indomethacin BP.

Polyethylene glycol suppositories containing 100 mg indomethacin BP.

Uses Non-steroidal anti-inflammatory agent with analgesic properties.

For the active stages of: rheumatoid arthritis; osteoarthritis; degenerative joint disease of the hip; ankylosing

spondylitis; acute peri-articular disorders such as bursitis, tendinitis, synovitis, tenosynovitis, capsulitis of the shoulder, sprains and strains; low-back pain (commonly called 'lumbago'); gout.

Also indicated in inflammation, pain and oedema following orthopaedic procedures; and the treatment of dysmenorrhoea and reduction of associated symptoms.

Indocid is not a simple analgesic, its use should be limited to the above conditions, and particularly those cases not responding to conservative measures.

Indocid Suppositories may be used where night pain and morning stiffness are prominent. One suppository at bedtime will frequently give relief from pain and stiffness for 13 to 16 hours after administration. Indocid Suppositories may reduce, but not always abolish, gastrointestinal side-effects of indomethacin therapy.

Indocid-R: Indocid-R may be substituted for all the indications of 'Indocid' except gout, as clinical evidence is not currently available for this dosage form in this condition.

Dosage and administration The dosage of Indocid should be carefully adjusted to suit the needs of the individual patient.

Oral therapy: In order to reduce the possibility of gastrointestinal disturbances, *Indocid/Indocid-R Capsules and Suspension should always be taken with food, milk or an antacid.* (Note, however, that Indocid Suspension should not be mixed with an antacid, but should be taken separately, because indomethacin is unstable in an alkaline medium.) Indocid Suspension should not be diluted.

In chronic conditions, starting therapy with a low dosage, increasing this gradually as necessary, and continuing a trial of therapy for an adequate period (in some cases, up to one month) will give the best results with a minimum of unwanted reactions.

The recommended oral dosage range is 50–200 mg daily. Paediatric dosage not established.

Dosage in dysmenorrhoea: Up to 75 mg a day, starting with onset of cramps or bleeding, and continuing for as long as the symptoms usually last.

Suppositories: Adults: 1 suppository to be inserted once or twice a day. One should be used at bedtime. If another is necessary, it should be used in the morning.

Dosage for Indocid-R: The sustained-release capsule may be given once or twice a day, depending on patient needs and response.

Contra-indications, warnings, etc

Contra-indications: Children (conditions for safe use not established); active peptic ulcer; a recurrent history of gastro-intestinal lesions; sensitivity to indomethacin or aspirin. Safety for use during pregnancy or lactation has not been established. Indocid Suppositories are contra-indicated in patients with a recent history of proctitis.

Precautions Headache, sometimes accompanied by dizziness and lightheadedness, may occur, usually early in treatment. Starting therapy with a low dosage and increasing it gradually will minimise the incidence of headache. These symptoms frequently disappear on continuing therapy or reducing the dosage, but if headache persists despite dosage reduction, Indocid should be withdrawn. Patients should be warned that they may experience dizziness and, if they do, should not drive a car or undertake potentially dangerous activities needing alertness. Indocid should be used cautiously in

patients with psychiatric disorders, epilepsy, or parkinsonism, as it may tend to aggravate these disorders.

Gastro-intestinal disturbances may be minimised by giving Indocid orally with food, milk or an antacid. They usually disappear on reducing the dosage; if not, the risks of continuing therapy should be weighed against the possible benefits. Indocid Suppositories may reduce gastro-intestinal disturbances.

Peptic ulcer has been reported in a small proportion of patients. Haemorrhage and perforation have occurred in a small proportion of patients, usually with a history of peptic ulcer or those receiving corticosteroids or salicylates concurrently. In some cases, however, there was no history of peptic ulcer, or of other agents being used. If gastro-intestinal bleeding does occur, Indocid should immediately be discontinued.

Tenesmus and irritation of the rectal mucosa (sigmoidoscopic examination of a number of patients showed no mucosal changes) have been reported with Indocid Suppositories.

Indocid may mask the signs and symptoms of infection, and antibiotic therapy should be initiated promptly if an infection occurs during therapy with Indocid. It should be used cautiously in patients with existing but controlled infection.

During prolonged therapy, periodic ophthalmological examinations are recommended, as corneal deposits and retinal disturbances have been reported.

Patients should be carefully observed to detect any unusual manifestations of drug sensitivity. Indocid should be used with particular care in the older patient, who may be more prone to adverse reactions.

Indocid Suppositories should be used with caution in patients with a recent history of rectal bleeding.

Drug interactions: Controlled clinical studies have shown that Indocid did not influence the hypoprothrombin-aemia produced by anticoagulants in patients and healthy subjects. Nevertheless, if Indocid is added to the treatment of patients receiving anticoagulant therapy, they should be observed closely for alterations of the prothrombin time.

When Indocid is given to patients receiving probenecid, the plasma levels of indomethacin are likely to be increased. Therefore, a lower total daily dosage of Indocid may produce a therapeutic effect, and when increases in the dose are made, they should be made cautiously and in small increments.

Warnings and adverse reactions: CNS reactions – headache, dizziness, and lightheadedness. Mental confusion, syncope, drowsiness, convulsions, coma, peripheral neuropathy, depression and other psychiatric disturbances such as depersonalisation may occur as transient reactions that often disappear with continued or reduced dosage. However, occasionally, severe reactions require stopping therapy.

Gastro-intestinal – the more frequent reactions are nausea, anorexia, vomiting, epigastric distress, abdominal pain and diarrhoea. Others are ulceration (single or multiple) of oesophagus, stomach, duodenum or elsewhere in the small intestine, sometimes with haemorrhage and perforation (a few fatalities have been reported); gastro-intestinal bleeding without obvious ulcer formation; increased abdominal pain in patients with pre-existing ulcerative colitis. Rarely, intestinal ulceration followed by stenosis and obstruction has been reported. Reactions occurring infrequently are stomatitis; gastritis; bleeding from the sigmoid colon (occult or from a diverticulum); perforation of pre-existing sigmoid

lesions such as diverticula and carcinomata; ulcerative colitis and regional ileitis (causal relationship not established). With suppositories, tenesmus and irritation of the rectal mucosa have occasionally been reported, but sigmoidoscopic examination in a number of cases has not revealed mucosal changes.

Hepatic – rarely, toxic hepatitis and jaundice (some fatalities reported).

Cardiovascular/renal – oedema, increased blood pressure, and haematuria (all infrequent).

Dermatological/hypersensitivity – pruritus, urticaria, angioneurotic oedema, angitis, erythema nodosum, skin rash, loss of hair, rapid fall in blood pressure resembling a shock-like state, and acute respiratory distress including sudden dyspnoea and asthma (all infrequent). Bronchospasm may be precipitated in patients suffering from or with a history of bronchial asthma or allergic disease.

Haematological – infrequently, blood dyscrasias may occur including leucopenia, purpura, aplastic and haemolytic anaemia, and particularly thrombocytopenia. Rarely, agranulocytosis and bone-marrow depression. Because some patients may develop anaemia secondary to obvious or occult gastrointestinal bleeding, appropriate blood determinations are recommended.

Ocular – infrequently, blurred vision, and orbital and peri-orbital pain. Corneal deposits and retinal disturbances including those of the macula reported in patients with rheumatoid arthritis on prolonged therapy, but similar changes seen in patients with rheumatoid arthritis who had not received Indocid.

Aural – infrequently, tinnitus (rarely, deafness).

Miscellaneous – vaginal bleeding, hyperglycaemia, glycosuria, epistaxis, ulcerative stomatitis.

The following adverse reactions have been associated with use of Indocid Suppositories: tenesmus; proctitis; rectal bleeding, burning, pain, discomfort, and itching.

Treatment of overdosage: If ingestion is recent, gastric lavage should be performed. Otherwise therapy is supportive; the progress of the patient should be followed for several days, as gastro-intestinal ulceration and haemorrhage are reported side-effects of indomethacin. Antacids may be helpful.

Pharmaceutical precautions Keep container well closed; store in a cool place, protected from light. Indocid Suspension should also be protected from freezing.

Indocid/Indocid-R Capsules and Suspension should always be taken with food, milk or an antacid. (Note, however, that Indocid Suspension should not be mixed with an antacid but should be taken separately because indomethacin is unstable in an alkaline medium.) Indocid Suspension should not be diluted.

Legal category POM.

Package quantities *Capsules:* 25 mg, bottles of 100 and 500; 50 mg, bottles of 100; 75 mg, bottles of 100.

Suppositories: Boxes of 10.

Suspension: Bottles of 200 ml.

Further information Nil.

MERUVAX* II ▼

Presentation Lyophilised powder for injection. When reconstituted, Meruvax II Injection contains in each dose not less than the equivalent of 1,000 TCID₅₀ (tissue culture infective doses) of rubella virus vaccine expressed in terms of the assigned titre of the FDA (USA) Reference Rubella Virus. It is prepared from the Wistar Institute RA 27/3 strain of live attenuated rubella virus, adapted to and propagated in human diploid cell (WI-38) culture.

Uses Immunisation against rubella.

Children between 12 months of age and puberty: Meruvax II is indicated for immunisation against rubella in boys and girls from 12 months of age to puberty. No booster is needed. It is not recommended for infants less than a year old because they may retain maternal rubella-neutralising antibodies which may interfere with the immune response. Children in kindergarten and the first years at infants' school deserve priority for vaccination because they often are epidemiologically the major source of virus dissemination in the community. A history of rubella illness is usually not reliable enough to exclude children for immunisation.

Unimmunised children of susceptible pregnant women should receive live attenuated rubella vaccine. By this protection, children are less likely to acquire natural rubella and introduce the virus into the household.

Adolescent and adult males: Vaccination of adolescent or adult males may be useful in preventing or controlling outbreaks of rubella in circumscribed population groups.

Post-pubertal females: Pregnant women **MUST NOT** be given live attenuated rubella virus vaccine.

Non-pregnant adolescent and adult females: Since it is not known to what extent infection of the foetus with attenuated virus might take place following vaccination, or whether damage to the foetus could result, routine immunisation of post-pubertal females of unknown rubella immune status should not be undertaken because of the danger of inadvertently administering vaccine before pregnancy becomes evident.

Post-pubertal females should be considered for vaccination individually. Vaccine should only be given if subjects are shown to be rubella-susceptible by serological testing (see below), if they are not pregnant at the time of vaccination, and if they agree that they will not become pregnant within three months following vaccination.

This cautious approach to the vaccination of post-pubertal females is indicated because of the potential risk from vaccination during pregnancy, and because congenital abnormalities occur in up to 7% of all live births. Their chance appearance after vaccination could lead to serious misinterpretation.

It has been found convenient, in many instances, to vaccinate rubella-susceptible women in the immediate post-partum period.

If vaccination of a post-pubertal female is contemplated, the following is recommended:

1. She should be tested for susceptibility to rubella by the single radial haemolysis (radial diffusion) test.
2. If immune, as evidenced by a specific rubella antibody titre of 15 international units (1 : 16) or greater, vaccination is unnecessary.
3. If susceptible, she may be vaccinated only if she agrees not to become pregnant for the next three months. (This precaution also applies to women in the immediate post-partum period.)

4. She should be informed of the frequent occurrence of self-limiting arthralgia and possibly of self limiting arthritis beginning two to four weeks after vaccination.

As with any vaccine, inoculation of susceptibles does not result in seroconversion in all the vaccinees.

Revaccination: Based on available evidence, there is no reason to revaccinate children who were vaccinated originally when 12 months of age or older; however, children vaccinated when younger than 12 months of age should be revaccinated. (Meruvax II is not recommended in infants less than 12 months of age.)

Use with other live virus vaccines: There are no data available concerning simultaneous use of Meruvax II with monovalent or trivalent poliovirus vaccine, live, oral, or with killed poliovirus vaccines. However serological evidence shows that when M-M-R* (Measles, Mumps and Rubella Virus Vaccine, Live, MSD), containing the HPV-77 rubella strain, is given simultaneously with trivalent poliovirus vaccine, live, oral, antibody responses can be expected to be comparable to those which follow administration of the vaccines at different times. From this it follows that when Meruvax II is given simultaneously with either monovalent or trivalent poliovirus vaccine, oral, Attenuvax* (Measles Virus Vaccine, Live, Attenuated) and/or Mumpsax* (Mumps Virus Vaccine, Live) antibody responses can be expected to be comparable to those which follow administration of the vaccines at different times.

Note: M-M-R is not currently available in the United Kingdom.

Dosage and administration The total volume reconstituted from the single-dose pack should be injected subcutaneously, preferably into the outer aspect of the upper arm, after suitably cleansing the immunisation site.

Meruvax II should not be injected intravenously, or administered intranasally.

Do not give immune serum globulin (ISG) with Meruvax II.

Reconstitution: To reconstitute the vaccine, all the diluent provided should be injected into a vial of lyophilised vaccine, and this agitated to ensure thorough mixing. All the reconstituted vaccine is then withdrawn into the syringe and injected subcutaneously.

Contra-indications, warnings, etc

Contra-indications: Do not give Meruvax II to pregnant females; the possible effects of the vaccine on foetal development are unknown at this time. When vaccination of post-pubertal females is undertaken, pregnancy must be avoided for three months following vaccination.

Hypersensitivity to neomycin. (Each dose of reconstituted vaccine contains approximately 25 mcg of neomycin.)

Any febrile respiratory illness, or other active or suspected infection.

Patients receiving therapy with ACTH, corticosteroids, irradiation, alkylating agents, or antimetabolites. This contra-indication does not apply to patients who are receiving corticosteroids as replacement therapy, e.g. for Addison's disease.

Individuals with blood dyscrasias, leukaemia, lymphomas of any type, or other malignant neoplasms affecting the bone marrow or lymphatic systems.

Primary immuno-deficiency states, including cellular immune deficiencies, hypogammaglobulinaemic and dysgammaglobulinaemic states.

History of convulsions. Parental history of non-traumatic epilepsy.

Precautions: Meruvax II is for subcutaneous administration; it must not be given intravenously.

Adrenaline should be available for immediate use should an anaphylactoid reaction occur.

Meruvax II may be given with monovalent or trivalent poliovirus vaccine, live, oral, with Attenuvax* (Measles Virus Vaccine, Live, Attenuated) and/or Mumpsax* (Mumps Virus Vaccine, Live).

Meruvax II should not be given less than one month before or after immunisation with other live virus vaccines.

Excretion of small amounts of live attenuated rubella virus from the nose and throat has occurred in the majority of susceptible individuals 7–28 days after vaccination. There is no definitive evidence to indicate that such virus is transmitted to susceptible persons who are in contact with vaccinated individuals. Consequently, transmission, while accepted as a theoretical possibility, has not been regarded as a significant risk.

Ideally, however, children should be vaccinated when there is no practical possibility of pregnancy in their mother.

There is no evidence that live rubella virus vaccine given after exposure will prevent illness. There is, however, no contra-indication to vaccinating children already exposed to natural rubella.

Vaccination should be deferred for at least three months following blood or plasma transfusions or administration of human immune serum globulin. However, susceptible post-partum patients who received blood products may receive Meruvax II prior to discharge provided that a recent HI titre is drawn 6–8 weeks after vaccination to insure seroconversion. Similarly, although studies with other live rubella virus vaccines suggest that Meruvax II may be given in the immediate post-partum period to those non-immune women who have received anti-Rh₀ (D) globulin (human) without interfering with vaccine effectiveness, a follow-up post-vaccination HI titre should also be determined.

It has been reported that live attenuated rubella vaccine may temporarily depress tuberculin skin sensitivity. If a tuberculin test is to be done, therefore, it should be administered before or simultaneously with Meruvax II.

Adverse reactions: Because the vaccine is slightly acidic (pH 6.2–6.6), patients may complain of burning and/or stinging at the injection site for a short time.

Adverse reactions are uncommon, but symptoms of the same kind as those seen following natural rubella may occur after vaccination. These include regional lymphadenopathy, urticaria, rash, malaise, sore throat, fever, headache, polyneuritis, and occasionally temporary arthralgia that is infrequently associated with signs of inflammation. Local pain, induration, wheal and flare, and erythema may occur at the injection site.

Moderate fever (38.3° to 39.3°C/101° to 102.9°F) occurs occasionally, and high fever (above 39.4°C/103°F) occurs less commonly.

Reactions are usually mild and transient.

In children, joint reactions are rare and of brief duration if they do occur. In women, incidence rates for arthritis and arthralgia are generally higher than those seen in children (children: 0–3%; women: 12–20%) and the reactions tend to be more marked and of longer duration. Rarely, symptoms may persist for a matter of months. In adolescent girls, the reactions appear to be intermediate in incidence between those seen in children and in adult women. Even in older women (35–45 years) these

reactions are generally well tolerated and rarely interfere with normal activities.

Clinical experience with Meruvax II indicates that encephalitis and other nervous system reactions have occurred very rarely. A cause-and-effect relationship has not been established.

In view of the decreases in platelet counts that have been reported, thrombocytopenic purpura is a theoretical hazard.

Pharmaceutical precautions During shipment, to insure that there is no loss of potency, the vaccine must be maintained at a temperature of 10°C (50°F) or less.

Before reconstitution, Meruvax II should be stored at 2° to 8°C (35.6° to 46.4°F), and protected from light. Only the diluent supplied should be used for reconstitution. The vaccine should be used immediately after reconstitution.

Colour: The vaccine when reconstituted is yellow.

Legal category POM.

Package quantities Single-dose vials of lyophilised vaccine with ampoules of sterile diluent.

Further information Meruvax II has been shown to induce rubella haemagglutination-inhibiting (HI) antibodies in over 97% of susceptible subjects.

Vaccine induced antibody levels have been shown to persist for at least six years without substantial decline. If the present pattern continues, it will provide a basis for the expectation that immunity following the vaccine will be permanent. However, continued surveillance will be required to demonstrate this point.

Product licence number 0025/0149.

MIDAMOR*

Presentation Yellow, diamond-shaped tablets, marked 'MSD 92', containing 5 mg amiloride hydrochloride.

Uses Potassium-conserving agent; diuretic.

Although Midamor has mild natriuretic, diuretic and antihypertensive activity when used alone which may be additive to the effects of thiazides and other saluretic-antihypertensive agents, its principal indication is as concurrent therapy with thiazides or more potent diuretics to conserve potassium during periods of vigorous diuresis and during long-term maintenance therapy.

In congestive heart failure, the positive effect of Midamor on potassium balance may be especially useful for patients also receiving digitalis, who are particularly sensitive to lowered potassium levels. In hypertension, it is used as an adjunct to therapy with thiazides and similar agents to prevent potassium depletion. When combined with hydrochlorothiazide, Midamor gives an additive antihypertensive action. In hepatic cirrhosis with ascites, Midamor usually provides adequate diuresis with diminished potassium loss and less risk of metabolic alkalosis, when used alone. It may be used with more potent diuretics when a greater diuresis is required.

Dosage and administration *Midamor alone:* The initial dosage should be 10 mg (as a single dose or 5 mg twice a day). This may be increased if necessary, but must not exceed 20 mg (4 tablets) a day. After diuresis has been achieved, the dosage may be reduced by 5 mg increments to the least amount required.

Midamor usually begins to act within two hours. Its effect upon electrolyte excretion reaches a peak between

six and ten hours, and lasts about 24 hours. Most patients respond during the first day of treatment, but maximum therapeutic effect may not be seen for several days. As in all diuretic therapy, the rate of weight loss and the serum electrolyte levels should determine the dosage. The most satisfactory rate of weight loss is generally about 0.5–1.0 kg a day.

Midamor with other diuretic therapy: When Midamor is used with a diuretic which is given on an intermittent basis, it should be given at the same time as the diuretic.

Congestive heart failure: Initially, 5 or 10 mg (1 or 2 tablets) a day, together with the usual dosage of the diuretic concurrently employed. If diuresis is not achieved with minimal dosage of both agents, the dosage of both may be gradually increased, but that of Midamor should not exceed 20 mg (4 tablets) a day. Once diuresis has been achieved, reduction in dosage of both agents may be attempted for maintenance therapy. The dosage of both drugs is determined by the diuresis and the level of serum potassium.

Hypertension: 5 or 10 mg (1 or 2 tablets) a day, together with the usual antihypertensive dosage of the thiazide concurrently employed. It is not usually necessary to exceed 10 mg of Midamor a day; in any event, not more than 20 mg (4 tablets) of Midamor a day should be given.

Hepatic cirrhosis with ascites: When used with another diuretic, treatment should be started with a small dose of Midamor, i.e. 5 mg (1 tablet), plus a low dosage of the other diuretic agent. If necessary, dosage of both agents may be increased gradually until there is effective diuresis.

The dosage of Midamor should not exceed 20 mg (4 tablets) a day. Maintenance doses may be lower than those required to initiate diuresis; reduction in the daily dosage should therefore be attempted when the patient's weight is stabilised. Gradual weight reduction in cirrhotic patients is especially desirable to reduce the likelihood of untoward reactions associated with diuretic therapy.

Contra-indications, warnings, etc

Contra-indications: Hyperkalaemia (serum potassium over 5.5 mEq/l); other potassium-conserving agents or potassium supplements; anuria, acute renal failure, severe progressive renal disease, diabetic nephropathy; patients with blood urea over 60 mg per 100 ml or serum creatinine over 1.5 mg per 100 ml should not receive amiloride hydrochloride without careful frequent monitoring of serum electrolytes and blood urea levels; prior sensitivity to amiloride hydrochloride. In renal impairment, use of a potassium conserving agent may result in rapid development of hyperkalaemia. Safety for use in children not established. See also 'Use in pregnancy' under 'Precautions'.

Precautions – Diabetes mellitus: Hyperkalaemia has commonly occurred in diabetic patients, especially those with chronic renal disease or pre-renal azotaemia. The status of renal function should therefore be determined before Midamor is given to known or suspected diabetic patients. Midamor should be discontinued before a glucose-tolerance test, as one patient with poorly controlled diabetes mellitus, who became severely hyperkalaemic while receiving amiloride hydrochloride, died following two repeated intravenous glucose-tolerance tests.

Metabolic or respiratory acidosis: Potassium-conserving therapy should be initiated only with caution in severely

ill patients in whom metabolic or respiratory acidosis may occur, e.g. patients with cardiopulmonary disease of decompensated diabetes. Shifts in acid-base balance alter the balance of extracellular-intracellular potassium, and the development of acidosis may be associated with rapid increases in serum potassium.

Hyperkalaemia (serum potassium level over 5.5 mEq/litre): This has been observed in patients receiving amiloride hydrochloride, alone or with other diuretics, particularly in the aged, in diabetics, and in hospital patients with hepatic cirrhosis or cardiac oedema who had known renal involvement, were seriously ill, or were undergoing vigorous diuretic therapy. Such patients should be observed carefully for clinical, laboratory, and ECG evidence of hyperkalaemia (not always associated with an abnormal ECG). Some deaths have been reported in this group of patients. If hyperkalaemia develops, Midamor should be discontinued immediately, and if necessary, active measures taken to reduce the serum potassium to normal.

Electrolyte imbalance and blood urea increases: Hyponatraemia and hypochloraemia may occur when amiloride hydrochloride is used with other oral diuretics. Reversible increases in blood urea levels have been reported accompanying vigorous diuresis, especially when diuretic combinations were used in seriously ill patients, such as those with hepatic cirrhosis with ascites and metabolic alkalosis, or those with resistant oedema. Careful monitoring of serum electrolytes and blood urea levels should therefore be carried out when Midamor is given with oral diuretics to such patients.

Effects in cirrhotic patients: Oral diuretic therapy is more frequently accompanied by adverse reactions in patients with hepatic cirrhosis and ascites, because these patients are intolerant of acute shifts in electrolyte balance, and because they often already have hypokalaemia as a result of associated aldosteronism. Hepatic encephalopathy, manifested by tremors, confusion and coma, has been reported. In cirrhotic patients, jaundice associated with the underlying disease process has deepened in a few instances, but the relationship to amiloride is uncertain.

Other precautions: As with any drug, patients should be observed regularly for the possible occurrence of liver dysfunction, idiosyncratic reactions or blood dyscrasias.

Use in pregnancy: Because clinical experience is limited, Midamor is not recommended for use during pregnancy. The potential benefits of the drug must be weighed against possible hazards to a foetus if it is administered to a woman of childbearing age.

Side-effects – Gastro-intestinal: Anorexia, nausea, vomiting, abdominal fullness, pain, constipation, diarrhoea.

Related to diuresis: Dry mouth and thirst, paraesthesiae, dizziness, weakness, susceptibility to fatigue, muscle cramps, orthostatic hypotension.

Other: Reversible adverse reactions reported with amiloride hydrochloride are skin rash, pruritus, and such minor psychiatric disturbances as confusion; transient visual disturbances have also been noted.

There have been isolated instances of gastro-intestinal bleeding in patients with a history of gastro-intestinal disease receiving amiloride hydrochloride alone; a relationship with amiloride has not been established.

Rare reversible abnormalities, thought to be related to amiloride hydrochloride, have been observed in liver

function tests. One patient with pre-existing partial heart block developed complete heart block following use of amiloride hydrochloride.

Treatment of overdosage: Dehydration, electrolyte imbalance and hepatic coma are treated by the established procedures. There is no specific antidote. Emesis should be induced or gastric lavage performed. Treatment is symptomatic and supportive. If hyperkalaemia occurs, active measures should be taken to reduce the serum potassium levels.

Pharmaceutical precautions Keep container well closed; store in a cool place, protected from light.

Legal category POM.

Package quantities Bottles of 100.

Further information Potassium supplements and other potassium-conserving agents are contra-indicated with Midamor.

Product licence number 0025/5015.

MODUCREN* ▼

Presentation Blue, square, half-scored tablets, marked 'MODUCREN', containing 25 mg hydrochlorothiazide, 2.5 mg amiloride hydrochloride, and 10 mg timolol maleate.

Uses Mild to moderate hypertension.

Dosage and administration 1 to 2 tablets once a day.

Contra-indications, warnings, etc

Contra-indications: Bronchospasm (including bronchial asthma), severe chronic obstructive pulmonary disease, sinus bradycardia (less than 50 beats per minute), second- and third-degree AV block, congestive heart failure, right ventricular failure secondary to pulmonary hypertension, significant cardiomegaly, and cardiogenic shock. Hyperkalaemia (serum potassium greater than 5.5 mEq/litre). Anuria, acute and chronic renal insufficiency, severe or progressive renal disease (blood urea more than 60 mg %, BUN more than 30 mg %, serum creatinine more than 1.5 mg %), diabetic nephropathy.

Anaesthetic agents causing myocardial depression, hypersensitivity to any component of Moducren or to sulphonamide-derived drugs. Use of other potassium-conserving agents or potassium supplements except in severe and/or refractory cases of hypokalaemia.

Precautions: *Congestive cardiac failure:* Care should be exercised before and during treatment of patients with cardiomegaly or history of cardiac failure. *Cardiac arrhythmias:* Patients at risk of congestive heart failure should be carefully observed for bradycardia, AV block and respiratory distress. If congestive cardiac failure persists, Moducren should be withdrawn. Moducren should be withdrawn gradually in patients with angina pectoris because abrupt withdrawal of beta blockers has been associated with increase in pain, and reports of myocardial infarction, and ventricular arrhythmias. *Elective or emergency surgery:* Moducren should also be gradually withdrawn prior to elective surgery of anginal patients. Agonists such as isoprenaline or noradrenaline may be used to counter the effects of beta-blockade in emergency surgery. *Renal and hepatic disease and electrolyte disturbances:* Moducren should be used with caution in patients with renal or hepatic disease and in

those patients in whom fluid and electrolyte balance is critical. Acid-base balance should be monitored frequently in severely ill patients at risk of respiratory acidosis. Serum and urine electrolyte determinations should be made in patients vomiting excessively or receiving parenteral fluids. Dilutional hyponatraemia may occur in patients with oedema in hot weather that calls for appropriate therapy; hypochloreaemia requires specific treatment only under exceptional circumstances. Hypokalaemia or hyperkalaemia may occur. *Diabetes mellitus, hypoglycaemia:* Moducren should be given with caution to diabetic patients and to patients subject to spontaneous hypoglycaemia as the symptoms and signs of acute hypoglycaemia may be masked. Moducren should only be used in diabetic patients after determining the status of renal function. Moducren should be discontinued at least three days before glucose tolerance testing. Insulin requirements may need readjusting in patients taking Moducren. *Skin and sensitivity reactions:* There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenergic blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuation of the drug should be considered if any such reaction is not otherwise explicable. Withdrawal should be gradual. Sensitivity reactions to Moducren may occur with or without a history of allergy or bronchial asthma. Possible exacerbation or activation of systemic lupus erythematosus reactions have been reported with thiazide diuretics. *Metabolic and endocrine:* Beta-adrenergic blocking agents may mask the signs of hyperthyroidism. Hypercalcaemia and hypophosphataemia have been reported with thiazide diuretics. Moducren should be discontinued in patients prior to testing for parathyroid function. Hyperuricaemia or acute gout may be precipitated in some patients.

Drug interactions: Moducren may potentiate other antihypertensive agents, such as reserpine or guanethidine. Its effect may be enhanced in the post-sympathectomy patient. Thiazides may increase the responsiveness to tubocurarine. Preparations containing lithium should not generally be given with diuretics because they reduce its renal clearance and add a high risk of lithium toxicity.

Children: Because the safety and efficacy of Moducren has not been established in children, it is not recommended for paediatric use.

Nursing mothers: Thiazides appear in breast milk, but it is not known whether timolol maleate or amiloride are also excreted. If the use of Moducren is deemed essential, the mother should stop nursing.

Pregnancy: Moducren is not recommended for use during pregnancy. The use of any drug in women of child-bearing age requires that the anticipated benefit be weighed against possible hazards, which include foetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult.

Warnings and adverse effects: Common side-effects reported are asthenia, fatigue, and bradycardia. Other effects relating to the components of Moducren are described below.

Hydrochlorothiazide and amiloride hydrochloride related effects. *Gastro-intestinal:* anorexia, nausea, vomiting, abdominal fullness or pain, flatulence, gastric irritation, cramp, constipation, diarrhoea. A few reports of gastro-intestinal bleeding associated with amiloride have been

made, although its relationship to amiloride is uncertain. Activation of probable pre-existing peptic ulcer has been reported in a few patients receiving amiloride.

Other: Rash, pruritus, transient visual disturbances, minor psychiatric disturbances such as confusion. Leucopenia, agranulocytosis, thrombocytopenia, aplastic anaemia, and haemolytic anaemia have been reported rarely following thiazide therapy. Purpura, urticaria, photosensitivity, necrotising angitis (vasculitis, cutaneous vasculitis), fever, respiratory distress, pneumonitis, and anaphylactic reactions have been reported. Blood dyscrasias have been reported rarely in patients receiving amiloride hydrochloride. Abnormalities of liver function tests thought to be related to amiloride have also been reported. Hyperuricaemia has been noted.

Thiazide therapy commonly causes headache, restlessness, jaundice (intrahepatic cholestatic jaundice), pancreatitis, xanthopsia, hyperglycaemia, glycosuria, and hyperuricaemia. One patient with hyperkalaemia and partial heart block developed complete heart block following the use of amiloride hydrochloride. Diuresis may also induce dry mouth and thirst, paraesthesiae, sialadenitis, dizziness, vertigo, weakness, muscle spasm, and orthostatic hypotension (aggravated by alcohol, barbiturates, or narcotics).

Timolol maleate related: Epigastric distress, nausea, vomiting, diarrhoea, dizziness, weakness, headache, and dyspnoea have been most commonly reported. Insomnia, increased dreaming, nightmares, congestive heart failure, severe bradycardia, bronchospasm, AV block, postural hypotension, cold extremities, Raynaud's phenomenon, fatigue, sedation, and mental depression have been reported infrequently. Hallucinations have occurred rarely.

Various rashes and pruritus have been reported in low incidence, and one case of exfoliative dermatitis has been reported.

Treatment of overdose: There is no experience of overdose with Moducen. Nevertheless, experience with its components suggests that therapy be stopped and that the patient is closely watched. If dehydration, electrolyte imbalance and hepatic coma occur, treat by the established procedures. There is no specific antidote. If ingestion is recent, emesis should be induced or gastric lavage performed. Treatment is symptomatic and supportive. If hyperkalaemia occurs, active measures should be taken to reduce the serum potassium levels. For respiratory impairment, oxygen or artificial respiration should be administered.

Severe symptomatic bradycardia: atropine sulphate, 0.25–2 mg intravenously, should be used to induce vagal blockade. If bradycardia persists, intravenous isoprenaline hydrochloride should be administered cautiously. In refractory cases, the use of a cardiac pacemaker may be considered.

Severe hypotension: a sympathomimetic pressor agent such as noradrenaline should be used. In refractory cases, the use of glucagon has been reported to be useful.

Bronchospasm: isoprenaline hydrochloride should be used. Additional therapy with aminophylline may be considered.

Acute cardiac failure: conventional therapy with digitalis, diuretics, and oxygen should be instituted immediately. In refractory cases, the use of intravenous aminophylline followed, if necessary, by glucagon has been reported useful.

Pharmaceutical precautions Store in a cool, dry place, protected from light.

Legal category POM.

Package quantities Calendar packs of 28 tablets.

Further information Similar dosage schedules and similar bioavailability rationalise the combination of hydrochlorothiazide (a saluretic), timolol maleate (a beta-adrenergic receptor blocking agent), and amiloride hydrochloride (a potassium-conserving agent) for the treatment of hypertension.

Product licence number 0025/0141.

MUMPSVAX*

Presentation Powder which, when reconstituted, contains in each dose not less than 5,000 TCID₅₀ (tissue culture infectious doses) of mumps virus vaccine expressed in terms of the assigned titre of the FDA (USA) Reference Mumps Virus. It is prepared from the Jeryl Lynn (B Level) strain, named after the patient from whom the virus was initially recovered.

Uses Mumps virus vaccine.

Mumps vaccine induces protective antibodies in essentially all non-immune recipients, provides protection against natural mumps in most cases, and has not been shown to cause significant systemic or local reactions. Evidence indicates that the mumps virus infection initiated by the vaccine is not contagious.

The vaccine is indicated for immunisation against mumps in children over 12 months of age, or adults. It is not recommended for children younger than this because they may retain maternal mumps-neutralising antibodies which may interfere with the immune response.

Recent serological evidence shows that when M-M-R* (measles, mumps, and rubella virus vaccine, live, MSD) is given simultaneously with trivalent oral polio virus vaccine, antibody responses can be expected to be comparable to those which follow administration of the vaccines at different times. From this, it follows that when Mumps vaccine is given simultaneously with either monovalent or trivalent oral polio virus vaccine, Attenuvax* (measles virus vaccine, live attenuated) and/or Meruvax* II (rubella virus vaccine, live), antibody responses can be expected to be comparable to those which follow administration of the vaccines at different times.

Note: M-M-R is not currently available in the United Kingdom.

Evidence indicates that the vaccine will not offer protection when given after exposure to natural mumps. It has been reported that immune serum globulin (human), in a dosage of 0.01–0.02 ml/lb (0.02–0.04 ml/kg), did not prevent the antibody response to the live vaccine when the two were administered simultaneously in opposite arms. However, protection afforded with this regime has not been established.

Adequate antibody levels, with continuing protection of vaccinated children exposed to mumps, have persisted for ten years without substantial decline. The pattern of antibody closely resembles that observed for natural mumps, although the antibody level is significantly lower than that following the natural infection. If this pattern continues, it will provide a basis for expectation that immunity following the vaccine will be permanent.

However, continued observation will be required to demonstrate this point.

Revaccination: Based on available evidence, there is no need to revaccinate children who were originally vaccinated when 12 months or older.

Dosage and administration To reconstitute the vaccine, all the diluent in the syringe should be injected into the vial of lyophilised vaccine, and agitated to ensure thorough mixing. The entire contents of the vial should then be drawn back into the syringe.

After suitably cleansing the immunisation site, the total volume of reconstituted vaccine should be injected subcutaneously, preferably into the outer aspect of the upper arm. Mumpsxvax must not be injected intravenously.

The dosage of vaccine is the same for all patients. *Do not give serum globulin (ISG) concurrently with Mumpsxvax.*

Contra-indications, warnings, etc

Contra-indications: Do not give Mumpsxvax to pregnant women, since the possible effects of the vaccine on foetal development are not known at this time. It is recommended that the possibility of pregnancy at the time of vaccination be ruled out, and that the possibility of pregnancy in the three months following vaccination be prevented by a medically acceptable method for pregnancy prevention.

Mumpsxvax should not be given to children less than 1 year of age.

Hypersensitivity to neomycin (each dose of reconstituted vaccine contains approximately 25 mcg of neomycin).

Malignant disease. Those with impaired immune responsiveness, whether occurring naturally or as a result of treatment with steroids, radiotherapy, cytotoxic drugs or other therapy. This contra-indication does not apply to patients who are receiving corticosteroids as replacement therapy, e.g. for Addison's disease.

Any active or suspected infection is reason for delaying vaccination.

Hypersensitivity to eggs, chicken, or chicken feathers: This vaccine is essentially devoid of potentially allergenic substances derived from host tissues (chick embryo). However, because the attenuated virus in this vaccine is propagated in cell cultures of chick embryo, there is a potential risk of hypersensitivity reactions in patients allergic to eggs, chicken, or chicken feathers. Widespread use of Mumpsxvax for over a decade has resulted in only rare, isolated reports of minor reactions attributed to allergens of this kind. Significantly, children known to be allergic to eggs, chicken, and chicken feathers experienced no reactions other than those previously seen in non-allergic children when given a vaccine similar in preparation to Mumpsxvax.

Precautions: Mumpsxvax is for subcutaneous injection; it must not be given intravenously.

Mumpsxvax may be given simultaneously with mono-valent or trivalent poliovirus vaccine, live, oral, with Attenuvax* and/or Meruvax* II.

Mumpsxvax should not be given less than one month before or after immunisation with other live virus vaccines.

Vaccination should be deferred for at least three months following blood or plasma transfusions, or administration of human immune serum globulin. If any of these substances have been used near to the time of

vaccination, a test for the presence of mumps antibody should be made at a later date.

It has been reported that live mumps virus vaccine may temporarily depress tuberculin skin sensitivity. Therefore, if a tuberculin test is to be done, it should be scheduled before or simultaneously with mumps vaccine.

A sterile syringe and Adrenaline Injection BP (1 : 1,000) should be ready for immediate use should an anaphylactoid reaction occur.

Adverse reactions: Because of the slight acidity of the vaccine (pH 6.2-6.6) patients may complain of burning and/or stinging at the injection site for a short time.

Mild fever occurs occasionally. Fever above 103°F (39.4°C) is uncommon.

Parotitis has been reported to occur in very low incidence, and orchitis rarely, in persons who were vaccinated. In most instances investigated, prior exposure to natural mumps was established. In other instances, whether or not this was due to vaccine, to prior natural mumps exposure or to other causes has not been established.

Reports of purpura and allergic reactions such as wheal and flare at the injection site, or urticaria have been extremely rare.

Very rarely, encephalitis and other nervous system reactions have occurred in recipients of the vaccine. A cause-effect relationship has not been established.

Treatment of overdosage: Nil.

Pharmaceutical precautions Prior to reconstitution, the vaccine should be stored in a refrigerator at 2-8°C (35.6-46.4°F). The vaccine should be protected from light at all times. Only the diluent supplied should be used, and the vaccine should be reconstituted just before using. It is recommended that the reconstituted vaccine should be used immediately after reconstitution.

To ensure that there is no loss of potency during shipment, the vaccine must be maintained at a temperature of 10°C (50°F) or less.

Colour: The reconstituted vaccine is yellow.

Legal category POM.

Package quantities One 0.5 ml single-dose vial of lyophilised vaccine, packed with a disposable syringe containing diluent.

Further information Mumpsxvax is grown in cell cultures of chick embryos free of avian leucosis, according to the general procedures used to prepare Enders' measles virus vaccine, live attenuated. The vaccine is tested for safety and efficacy.

No reports have been received of transmission of mumps from vaccinees to susceptible contacts.

Product licence number 0025/0072.

PNEUMOVAX* ▼

Presentation Single-dose, prefilled syringe containing, in 0.5 ml, 50 mcg of each polysaccharide type derived from capsules of the fourteen most prevalent pneumococci dissolved in isotonic saline containing 0.25% phenol.

Uses A pneumococcal vaccine affording protection against the fourteen most prevalent or invasive capsular types of pneumococci accounting for at least 80% of pneumococcal disease isolates found by ongoing surveillance (see chart).

14 pneumococcal capsular types included in Pneumovax

Nomenclature		Pneumococcal types						
US	1	2	3	4	6	8	9	
Danish	1	2	3	4	6A	8	9N	
US	12	14	19	23	25	51	56	
Danish	12F	14	19F	23F	25	7F	18C	

Pneumovax is indicated for immunisation against pneumonia and bacteraemia caused by those types of pneumococci included in the vaccine. It should be considered for all persons 2 years of age or older in whom there is an increased risk of morbidity and mortality from pneumococcal pneumonia.

However, Pneumovax may not be effective in preventing infection resulting from basilar skull fracture or from external communication with cerebrospinal fluid. Studies are under way to determine the effectiveness of the vaccine for preventing pneumococcal otitis media in infants.

Dosage and administration *Do not inject intravascularly; avoid intradermal administration.*

Administer a single 0.5 ml dose of Pneumovax subcutaneously or intramuscularly (preferably in the deltoid muscle or lateral mid-thigh) with appropriate precautions to avoid intravascular administration.

Available data suggest that revaccination should not be carried out at less than five-year intervals to minimise the frequency and severity of local reactions, especially in persons who have retained high antibody levels.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to any component of the vaccine. Adrenaline Injection BP (1 : 1,000) must be immediately available should an acute anaphylactoid reaction occur.

Do not give Pneumovax during pregnancy; the possible effects of the vaccine on foetal development are unknown.

Patients with Hodgkin's disease who have received extensive chemotherapy and/or nodal irradiation.

Warnings:

The expected serum antibody response may not be obtained in patients receiving immunosuppressive therapy.

Intradermal administration may cause severe local reactions.

Required prophylactic antibiotic therapy against pneumococcal infection should not be stopped after immunisation with Pneumovax.

Precautions: Delay the use of Pneumovax in any febrile respiratory illness or other active infection except when this delay may involve even greater risk.

Caution and appropriate care should be exercised in administering Pneumovax to individuals with severely compromised cardiac and/or pulmonary function in whom a systemic reaction would pose a significant risk.

Available data suggest that revaccination before five years may result in more frequent and severe local reactions at the site of injection.

Children under 2 years of age: Pneumovax is not recommended because antibody response to some pneumococcal capsular types may be poor.

Nursing mothers: Because it is not known whether

Pneumovax is excreted in human milk, exercise caution when giving the vaccine to nursing mothers.

Adverse reactions: Local erythema and soreness at the injection site, usually of less than 48 hours' duration, commonly occur; local induration occurs less frequently.

Low-grade fever (less than 100.9°F) occurs occasionally, usually within 24 hours of vaccination. Rarely, fever over 102°F has been reported.

Reactions of greater severity, duration, or extent are unusual.

Rarely, anaphylactoid reactions have been reported.

Pharmaceutical precautions Store at 2–8°C. The vaccine is used directly as supplied. No dilution or reconstitution is necessary. Phenol in 0.25% is present as preservative.

Pneumovax should be inspected before injection to see that it is a clear, colourless liquid without suspended particles.

All vaccine must be discarded after the expiration date.

Legal category POM.

Package quantities A single-dose, prefilled syringe.

Further information Pneumovax is a polysaccharide vaccine. The vaccine does not contain pneumococcal bacteria, but highly purified chemicals derived from the protective capsules which the bacteria produce. These are called capsular polysaccharides. It has been established that the purified capsular polysaccharides of pneumococci induce antibody production and that such antibody is effective in preventing pneumococcal disease.

Antibody levels develop by the third week following vaccination. Although the duration of protection is at present unknown, previous studies with other pneumococcal vaccines suggest that antibody protection may persist for five years. Type-specific antibody levels induced by Pneumovax decline over a 42-month period of observation, but remain significantly higher than prevaccination levels in almost all recipients who responded initially.

Invasive pneumococcal disease causes high morbidity and mortality in spite of effective antimicrobial control by antibiotics. These effects of pneumococcal disease appear due to irreversible physiological damage caused by the bacteria during the first five days following onset of illness, and irrespective of antimicrobial therapy.

Product licence number 0025/0137.

TRYPTIZOL*

Presentation Tryptizol 75, clear orange, slow-release capsules, marked 'MSD 649', containing 75 mg amitriptyline hydrochloride BP as a pelleted formulation.

Blue, film-coated tablets, marked 'MSD 23', containing 10 mg amitriptyline hydrochloride BP; yellow, film-coated tablets, marked 'MSD 45', containing 25 mg; and brown, film-coated tablets, marked 'MSD 102', containing 50 mg.

Injection, a colourless solution containing per ml 10 mg amitriptyline hydrochloride.

Syrup, a pink suspension containing, in each 5 ml, amitriptyline embonate BP equivalent to 10 mg amitriptyline.

Uses Depression (especially where sedation is required); also effective in nocturnal enuresis where organic pathology is excluded.

Dosage and administration *Depression.*

Oral therapy: Therapy should be started with a low dosage and increased gradually, according to the clinical response and any evidence of intolerance.

Adults – initial dosage: Usually 75 mg a day in divided doses. If necessary, this may be increased to a total of 150 mg a day, the additional doses being given in the late afternoon and/or at bedtime.

A small number of hospitalised patients may require as much as 300 mg a day. Appropriate care must be taken when doses of this level are used.

The sedative effect is usually rapidly apparent. The antidepressant activity may be seen within three or four days or may take up to 30 days to develop adequately.

Adults – maintenance dosage: usually 50–100 mg a day. For maintenance therapy, the total dosage may be given in a single dose preferably in the evening or at bedtime. When satisfactory improvement has been reached, dosage should be reduced to the lowest amount that will maintain relief of symptoms. Maintenance therapy should be continued for three months or longer to lessen the chances of relapse.

Elderly patients: In general, lower dosages are recommended for these patients. A daily dosage of 50 mg may be satisfactory in elderly patients who may not tolerate higher dosages. The required dosage may be administered either as divided doses or as a single dose preferably in the evening or at bedtime.

Parenteral therapy: Parenteral use of amitriptyline should be restricted to patients for whom oral therapy is inappropriate or difficult. Substitute oral therapy as soon as possible. Give 1–2 ml (10–20 mg) four times a day, intramuscularly or intravenously.

Children: Due to lack of clinical experience, Tryptizol is not recommended for the treatment of *depression* in children under 12 years of age.

Enuresis: Children aged 6–10 years may receive 10–20 mg a day, while those aged 11–16 years may need 25–50 mg a day. The recommended dosage must not be exceeded, and therefore Tryptizol 75 is not suitable for the treatment of enuresis. Treatment should not exceed three months.

This medication should be kept out of the reach of children. Tryptizol Syrup can be diluted with Syrup BP.

Because of the wide variation in the absorption and distribution of tricyclic antidepressants in body fluids, dosage should be adjusted to clinical response and not based on plasma levels. However, plasma levels may be used as a guide to toxicity or to non-compliance.

Contra-indications, warnings, etc

Contra-indications: Co-administration with monoamine oxidase inhibitors; prior sensitisation to amitriptyline; not recommended during the immediate recovery phase after myocardial infarction; arrhythmias, particularly heartblock of any degree; mania; severe liver disease; lactation; children under 6 years of age. See also 'Use in pregnancy and the nursing mother', under 'Precautions'.

Precautions: Tryptizol should be used with caution in patients with a history of epilepsy, in patients with impaired liver function and, because of its atropine-like action, in patients with a history of urinary retention, prostatic hypertrophy, narrow-angle glaucoma, or increased intra-ocular pressure. In patients with narrow-angle glaucoma even average doses may precipitate an attack of glaucoma.

Patients with cardiovascular disorders, hyperthyroid

patients, and those receiving thyroid medication or anticholinergic agents should be closely supervised and the dosage of all medications carefully adjusted.

Elderly patients are particularly liable to experience adverse reactions: especially agitation, confusion, and postural hypotension.

Tryptizol may impair alertness in some patients and activities made hazardous by diminished alertness (e.g. driving a car) should be avoided.

When Tryptizol is used for the depressive component of schizophrenia, psychotic symptoms may be aggravated. In manic-depressives, a shift towards the manic phase may occur; paranoid delusions, with or without associated hostility, may be aggravated. In such cases, a major tranquilliser should be given concurrently, or the dosage of Tryptizol reduced.

The risk of suicide remains during treatment of depressed patients and until significant remission occurs. Such patients require careful supervision.

Concurrent administration with ECT may increase the hazards of treatment, and should be limited to patients for whom it is deemed essential. If possible, Tryptizol should be discontinued several days before elective surgery because anaesthesia increases the risk of hypotension and arrhythmias.

Behavioural changes have been observed in children receiving tricyclics for the treatment of enuresis.

Use in pregnancy and the nursing mother: The safety of Tryptizol for use during pregnancy and lactation has not been established. Tryptizol is not recommended during pregnancy, especially during the first and third trimesters unless there are compelling reasons, and in these patients the benefits should be weighed against possible hazards to the foetus, child, or mother. Animal reproduction studies have been inconclusive, and clinical experience has been limited.

Drug interactions: The concurrent use of antidepressants having varying modes of action should be made only with due recognition of their possible potentiation and with a thorough knowledge of their respective pharmacologies. Monoamine oxidase inhibitors can potentiate the effects of tricyclic antidepressants such as Tryptizol, and hyperpyretic crises, severe convulsions, and fatalities have occurred. A minimum of 14 days should elapse between discontinuing an MAOI and starting Tryptizol, which should be introduced cautiously and dosage increased gradually.

Tryptizol may block the antihypertensive action of guanethidine, debrisoquine, bethanidine, and possibly clonidine. It would be advisable to review all antihypertensive therapy during treatment with tricyclic antidepressants.

Amitriptyline should not be given with sympathomimetic agents such as adrenaline, ephedrine, isoprenaline, noradrenaline, phenylephrine, and phenylpropanolamine.

Tryptizol may enhance the response to alcohol, barbiturates, and other CNS depressants. In turn, barbiturates may decrease, and methylphenidate may increase, the antidepressant action of amitriptyline.

Paralytic ileus may occur in patients taking tricyclic antidepressants in combination with drugs having an anticholinergic action.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients treated with 1 g ethchlorvynol and 75 mg to 150 mg of Tryptizol.

Warnings and adverse effects: In general, Tryptizol is

well tolerated. The side effects given below are essentially a combined list of all those of the tricyclic group of antidepressants. Some of them have not been reported with Tryptizol, but are included because of the similar pharmacologies of the group members. As the antidepressant effects of Tryptizol may not become apparent for the first 2–4 weeks of therapy, patients should be closely monitored during this period.

Cardiovascular reactions: hypotension, postural hypotension, hypertension, tachycardia, palpitations, myocardial infarction, arrhythmias, heart block, stroke. Arrhythmias and severe hypotension are likely to occur with high dosage or in deliberate overdosage.

CNS and neuromuscular: confusional states, disturbed concentration, disorientation, delusions, hallucinations, hypomania, excitement, anxiety, restlessness, insomnia, nightmares, numbness, tingling, and paraesthesiae of the extremities, peripheral neuropathy, incoordination, ataxia, tremors, convulsions, alteration of the EEG, extrapyramidal symptoms, tinnitus.

Anticholinergic: dry mouth, blurred vision, disturbance of accommodation, increased intra-ocular pressure, constipation, paralytic ileus, urinary retention, urinary tract dilatation.

Allergic: skin rash, urticaria, photosensitisation, oedema of face and tongue.

Haematological: bone-marrow depression including agranulocytosis, leucopenia, eosinophilia, purpura, thrombocytopenia.

Gastro-intestinal: nausea, epigastric distress, vomiting, anorexia, stomatitis, unpleasant taste, diarrhoea, parotid swelling, black tongue, rarely hepatitis (including altered liver function and jaundice).

Endocrine: testicular swelling, gynaecomastia; breast enlargement, galactorrhoea, increased or decreased libido, interference with sexual function, elevation or lowering of blood sugar levels, syndrome of inappropriate ADH (antidiuretic hormone) secretion.

Other reactions: dizziness, weakness, fatigue, headache, weight loss, increased perspiration, urinary frequency, mydriasis, alopecia, drowsiness, increased appetite and weight gain (may be a drug reaction or due to relief of the depression). Abrupt withdrawal after prolonged administration has caused nausea, headache and malaise. This is not indicative of addiction.

Adverse reactions such as withdrawal symptoms, respiratory depression and agitation have been reported in neonates whose mothers had taken tricyclic antidepressants in the last trimester of pregnancy.

Side-effects in enuresis: Dosages used in enuresis are low compared with those used in depression, and side-effects are therefore less frequent. The most common are drowsiness and anticholinergic effects. The only other side-effects, reported infrequently at these dosages, have been mild sweating and itching.

Treatment of overdosage: All persons suspected of having taken an overdosage should be admitted to hospital as soon as possible. Treatment is symptomatic and supportive. The stomach should be emptied as quickly as possible by emesis, followed by gastric lavage

upon arrival at hospital. Following lavage, activated charcoal may be given during the first 24–48 hours at a dosage of 20–30 g every four to six hours. An ECG should be taken and close monitoring of cardiac function instituted if there is any sign of abnormality. An open airway and an adequate fluid intake should be maintained, and body temperature regulated.

Intravenous physostigmine salicylate, 1–3 mg, has been reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolised, the dosage of physostigmine should be repeated as required, particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dose of physostigmine. Because physostigmine itself may be toxic, it is not recommended for routine use.

Standard measures should be used to manage circulatory shock and metabolic acidosis. Cardiac arrhythmias may be treated with neostigmine, pyridostigmine or propanolol. Should cardiac failure occur, use of digitalis should be considered. Close monitoring of cardiac function for not less than five days is advisable.

If convulsions occur, they should be treated with paraldehyde, diazepam or an inhalation anaesthetic. Barbiturates should not be used because Tryptizol increases their CNS-depressant action.

Dialysis is of no value because of low plasma concentrations of amitriptyline. Since overdosage is often deliberate, patients may attempt suicide by other means during the recovery phase. Deaths by deliberate or accidental overdosage have occurred with this class of medicament.

Pharmaceutical precautions Keep containers well closed; store in a cool place, protected from light. The injection and the syrup should also be protected from freezing. Tryptizol Syrup may be diluted with Syrup BP; the mixture should be used within 14 days.

Legal category POM.

Package quantities *Capsules 75 mg:* Bottles of 100.

Tablets 10 mg: Bottles of 100 and 500.

Tablets 25 mg: Bottles of 100 and 500.

Tablets 50 mg: Bottles of 100.

Injection: Vials of 10 ml.

Syrup: Bottles of 200 ml and 1,000 ml.

Further information Tryptizol is a member of the tricyclic group of antidepressants. Its mode of action in man is not known, but it is not a monoamine oxidase inhibitor (special dietary restrictions are not necessary), and it does not act primarily by stimulating the CNS. It has not produced addiction.

AKROTHERM*

Presentation A white ointment containing; Histamine Base 0.034% w/w, Acetylcholine chloride USP 0.20% w/w, Cholesterol USP 1.00% w/w.

Uses Akrotherm exerts a local vasodilator action in the topical treatment of chilblains.

Dosage and administration Gently massage Akrotherm into the affected area three to four times a day.

Contra-indications, warnings, etc None.

Pharmaceutical precautions None.

Legal category P.

Package quantities Tube of 40 g.

Further information May be used on broken chilblains and in conjunction with systemic treatment – provides immediate relief from the itching and burning sensation.

Product licence number 0199/5011.

AUDAX* ANALGESIC EAR DROPS

Presentation Ear drops containing the Mundisal* brand of choline salicylate 20% w/v and of the penetrant ethylene oxide-polyoxypropyleneglycol condensate 1.25% w/v.

Uses For relief of pain, particularly in acute otitis media. Also of use in acute and chronic painful otitis externa and painful chronic otitis media and otalgia generally.

Dosage and administration *Infants, children and adults:* With head tilted to one side the external auditory canal is filled with Audax ear drops. The ear should be plugged with cotton wool soaked with the ear drops or a wick may be inserted if preferred. Audax ear drops should be instilled four-hourly until permanent relief of symptoms is obtained. Cleansing of the ear where necessary facilitates therapy.

Contra-indications, warnings, etc Salicylate sensitivity.

Where infection of the ear necessitates topical and/or systemic antibiotics, the Audax ear drops are designed as an adjuvant therapy.

Pharmaceutical precautions Store in a cool dry area protected from light.

Legal category P.

Package quantities Bottle containing 8 ml with separate dropper.

Further information The low surface tension of Audax ensures rapid penetration of the drops. The choline salicylate gives quick and prolonged analgesia. The pH of Audax ear drops is adjusted to approximate

closely that normally found in the external auditory meatus.

Audax ear drops contain no irritants or sensitising local anaesthetics. Audax ear drops eliminate the need to resort to oral salicylates and other systemic analgesics. In addition, Audax ear drops exert local anti-inflammatory and antipruritic effects in the ear and have their own spectrum of antimicrobial activity.

Product licence number 0337/5004.

BETADINE* AEROSOL SPRAY

Presentation Pressurised bottle containing a golden-brown solution of the Mundidone* brand of Povidone-Iodine USP 5% w/v with nitrogen as the propellant.

Uses As a skin antiseptic for treatment or prevention of infection and to aid healing in ulcers, burns, minor injuries, incisions, etc.

Dosage and administration *Adults, children and infants:* Hold the Betadine aerosol spray about 10 inches from the area to be treated; press valve firmly forwards and downwards to allow the spray to cover the desired area. Allow to dry.

Contra-indications, warnings, etc Do not spray into open eyes. In rare instances of local irritation or sensitivity discontinue treatment.

Pharmaceutical precautions Store in a cool dry place protected from light.

Legal category GSL.

Package quantities Aerosol spray of 88 ml.

Further information Betadine aerosol spray contains Povidone-Iodine, which retains the broad germicidal spectrum of iodine, but is non-stinging and non-irritating to sensitive denuded skin areas.

Betadine aerosol spray is rapidly microbicidal and quickly forms a protective film subjecting pathogens to the prompt and continued germicidal action of Povidone-Iodine.

Product licence number 0337/5022.

BETADINE* ANTISEPTIC PAINT

Presentation A golden brown, alcoholic solution containing the Mundidone* brand of Povidone-Iodine USP 10% w/v.

Uses As a general topical and quick drying antiseptic in the treatment and prevention of infection. It is ideal for Herpes simplex, Herpes zoster, grazes, abrasions, cuts and wounds, or any break in the skin which requires protection from infection.

Betadine antiseptic paint is effective in the treatment

of dermal infections caused by bacteria, fungi, yeasts, and viruses (e.g. Herpesvirus Types I and II).

Dosage and administration Apply Betadine antiseptic paint undiluted, as necessary, to affected area and allow to dry. Use twice daily, and cover with a dressing if desired.

Rinse the brush thoroughly after use.

Contra-indications, warnings, etc In rare instances of local irritation or sensitivity, discontinue treatment.

Pharmaceutical precautions Store in a cool, dry place protected from light.

Legal category P.

Package quantities Glass bottles containing 8 ml with an applicator brush.

Further information Numerous studies have established the rapid microbicidal activity of the Mupidone* brand of Povidone-Iodine contained in Betadine antiseptic paint, both in vivo and in vitro, against Gram-negative and Gram-positive bacteria, fungi, viruses and yeasts. Betadine antiseptic paint is also sporicidal.

Betadine antiseptic paint is effective in the presence of serum, blood, purulent exudate and necrotic tissue.

The applicator brush provided with Betadine antiseptic paint is for ease of application to minor wounds and infections. Rapid, prolonged and complete antiseptic cover is afforded by the use of Betadine antiseptic paint when applied topically twice daily.

Product licence number 0337/0047.

BETADINE* ANTISEPTIC SOLUTION BETADINE* ALCOHOLIC SOLUTION BETADINE* SURGICAL SCRUB

Presentation *Antiseptic Solution:* An aqueous solution containing the Mupidone* brand of Povidone-Iodine USP 10% w/v.

Alcoholic Solution: Contains the Mupidone* brand of Povidone-Iodine USP 10% w/v in an alcoholic solution.

Surgical Scrub: Contains the Mupidone* brand of Povidone-Iodine USP, 7.5% w/v with non-ionic surfactants.

All the preparations are golden-brown in colour.

Uses Degerming the skin pre-operatively and post-operatively for major and minor surgical procedures, and also in the case of the surgical scrub for pre-operative scrubbing and washing by surgeons and theatre staff.

Dosage and administration The antiseptic and alcoholic solutions should be applied full strength as often as needed. The surgical scrub should be used as a pre-operative antiseptic skin cleanser.

Contra-indications, warnings, etc A patch test should be performed in rare cases of iodine sensitivity.

Pharmaceutical precautions Store in a cool, dry place protected from light.

Legal category P.

Package quantities Containers of 500 ml and 5 litres.

Further information Numerous studies have established the rapid microbicidal activity of Povidone-Iodine contained in Betadine germicides, both in vitro and in vivo, against Gram-negative and Gram-positive bacteria,

fungi, protozoa, viruses and yeasts. Povidone-Iodine is also sporicidal.

Betadine scrub and solutions have a rapid and prolonged germicidal action and with repeat usage a cumulative germicidal effect.

Betadine scrub and solutions are active in the presence of serum, blood, purulent exudate and necrotic tissue.

They can be used for the preparation of skin and mucous membranes and for burn and wound disinfection without the risk of systemic toxicity.

Povidone-Iodine as contained in Betadine germicides is not inactivated by soap.

Surgical scrub	0337/5903

BETADINE* GARGLE AND MOUTH WASH

Presentation A pleasantly flavoured solution containing the Mupidone* brand of Povidone-Iodine USP 1% w/v. Amber in colour.

Uses For infected inflammatory conditions of the mouth and pharynx caused by bacterial or monilial infections, and in dental surgery.

Dosage and administration *Adults and children:* Use undiluted, or dilute with an equal volume of warm water. Gargle or rinse for at least 30 seconds. Repeat every two to four hours for as long as required.

Contra-indications, warnings, etc In rare instance of local irritation or sensitivity discontinue treatment.

Pharmaceutical precautions Store in a cool dry place protected from light.

Legal category P.

Package quantities Bottles containing 250 ml.

Further information Betadine gargle and mouth wash contains Povidone-Iodine, a complex of iodine which retains all the broad-spectrum germicidal activity of elemental iodine without its disadvantages.

The germicidal activity is maintained in the presence of blood, pus, serum and necrotic tissue.

Betadine gargle and mouth wash does not stain the skin, mucous membranes or teeth despite its powerful germicidal action.

Betadine gargle and mouth wash kills bacteria, viruses, fungi, spores and protozoa and rapidly reduces oral bacterial counts.

Product licence number 0337/0009.

BETADINE* OINTMENT

Presentation A golden-brown, water-soluble ointment containing the Mupidone* brand of Povidone-Iodine USP 10% w/w.

Uses For the treatment or prevention of infection in cuts and abrasions, minor surgical procedures and burns.

Dosage and administration *Adults, children and infants:* The affected skin should be cleaned and dried. Apply Betadine ointment liberally. May be covered with a dressing or bandage. Betadine ointment may be used as often as is required. In the treatment of burns, every

eight hours; in other treatments, apply once daily generally.

Contra-indications, warnings, etc In rare instance of local irritation or sensitivity, discontinue treatment.

Pharmaceutical precautions *Tubes:* Store in a well-closed container in a cool, dry place.

Sachets: Store in a cool dry place.

Legal category GSL.

Package quantities Sachets of 1 g. Tubes of 60 g. Jars of 500 g.

Further information Nil.

Product licence number 0337/5005.

BETADINE* SCALP AND SKIN CLEANSER

Presentation A golden-brown cleansing and sudsing surfactant solution containing the Mundidone* brand of Povidone-iodine USP 7.5% w/v.

Uses For seborrhoeic conditions of skin and scalp, acne vulgaris and other pyogenic skin conditions.

Dosage and administration *For hair and scalp:* Thoroughly wet the hair. Apply as a shampoo to the hair and scalp, rubbing well in. Allow to remain on the scalp for at least five minutes, rinse off with warm water. Reapply and work up into a rich lather before rinsing again.

For skin: Apply directly or with moistened sponge. Cleanse area thoroughly; repeat application and dry with clean or sterile towel or gauze.

Contra-indications, warnings, etc In rare instance of local irritation or sensitivity discontinue treatment.

Pharmaceutical precautions Store in a cool place protected from light.

Legal category GSL.

Package quantities Plastic squeeze bottle containing 100 ml.

Further information Betadine scalp and skin cleanser is neither a primary irritant nor a sensitiser.

It has a highly effective germicidal activity and is free from unpleasant odour.

Betadine scalp and skin cleanser is active in the presence of exfoliate debris and infected scalp lesions, does not stain the skin and does not sting the skin or the eyes. It possesses powerful deodorising properties.

Product licence number 0337/5023.

BETADINE* SHAMPOO

Presentation A golden-brown, cleansing and sudsing surfactant solution containing the Mundidone* brand of Povidone-iodine USP 4% w/v and lanolin.

Uses Seborrhoeic conditions of the scalp associated with excessive dandruff, pruritus, scaling, exudation and erythema of the scalp. Pityriasis capitis. Infected lesions of the scalp – pyoderma (recurrent furunculosis, infective folliculitis and impetigo). Cradle-cap.

Dosage and administration *For adults, children and infants:*

1. Having first wetted the hair apply two or three

capfuls of Betadine shampoo; use warm water to lather. Rinse.

2. Again apply two or three capfuls of Betadine shampoo and massage into the scalp with the tips of the fingers.

3. Work up to a golden lather using warm water.

4. Repeat treatment twice weekly until improvement is noted. Afterwards use Betadine shampoo once a week.

Contra-indications, warnings, etc In rare instance of local irritation or sensitivity, discontinue treatment.

Pharmaceutical precautions Store in a cool place protected from light.

Legal category GSL.

Package quantities Plastic squeeze bottle containing 100 ml.

Further information Betadine shampoo is neither a primary irritant nor a sensitiser.

It has a highly effective germicidal activity and is free from unpleasant odour.

Betadine shampoo is active in the presence of exfoliate debris and infected scalp lesions, does not stain the skin and does not sting the skin or the eyes. It possesses powerful deodorising properties.

Product licence number 0337/5033.

BETADINE* SKIN CLEANSER

Presentation A penetrating golden-brown, sudsing surfactant solution containing the Mundidone* brand of Povidone-iodine USP 4% w/v.

Uses Acne vulgaris of the face and neck, and other pyogenic skin conditions. As an adjuvant to systemic antibiotic therapy in treating septic lesions. For disinfection of the skin (as a liquid soap).

Dosage and administration Apply directly or with moistened sponge to the affected areas, and work up a rich lather. Allow to remain on the skin for three to five minutes, then rinse off thoroughly with warm water and dry with clean or sterile towel or gauze. For pyoderma, repeat twice a day until improvement is noted, and then once a day.

Contra-indications, warnings, etc In rare instance of local irritation or sensitivity, discontinue treatment.

Pharmaceutical precautions Store in a cool place protected from light.

Legal category GSL.

Package quantities Plastic squeeze bottle containing 100 ml.

Further information Betadine skin cleanser is neither a primary irritant nor a sensitiser.

It has a highly effective germicidal activity and is free from unpleasant odour.

Betadine skin cleanser is active in the presence of exfoliate debris and infected skin lesions, does not stain the skin and does not sting the skin or eyes. It possesses powerful deodorising properties.

Product licence number 0337/5034.

BETADINE* SKIN CLEANSER FOAM

Presentation A rich, penetrating cleansing foam,

containing the Mundidone* brand of Povidone-Iodine USP 7.5% w/v.

Uses For pyogenic and seborrhoeic skin infections particularly acne vulgaris and sycosis barbae. As an adjuvant to systemic antibiotic therapy in treating septic lesions. Ideal for disinfection of the hands and skin.

Dosage and administration Shake aerosol bottle well before use. Wet skin and with unit held upright, apply sufficient amount of Betadine skin cleanser foam, preferably with an abrasive sponge, to work up a rich, golden lather. Allow lather to remain on skin for about three minutes. Rinse thoroughly with warm water. Repeat twice a day until improvement is noted. For skin disinfection, use Betadine skin cleanser foam as a soap.

Contra-indications, warnings, etc In rare instance of local irritation or sensitivity, discontinue treatment. Contents under pressure. Do not puncture or store near heat or open flame. Never throw container into fire or incinerator.

Pharmaceutical precautions Store in a cool dry place protected from light, heat and flame.

Legal category GSL.

Package quantities Plastic-coated aerosol bottle containing 100 g.

Further information Betadine skin cleanser foam contains the broad-spectrum microbicide Povidone-Iodine. It is therefore a preparation with rapid bactericidal, fungicidal, sporicidal, protozoacidal and virucidal properties, being particularly effective against the organisms commonly associated with acne and other pyogenic skin conditions, i.e. *Staphylococcus aureus* and *Streptococcus sp.*

Betadine skin cleanser foam is non-stinging, non-staining and non-sensitising to skin and mucosa while retaining the full spectrum of activity of iodine.

The surfactant nature of the rich foam actively degreases seborrhoeic skin conditions, prevents the spread of further infection and preserves the acid mantle of the skin.

Product licence number 0337/0034.

BETADINE* VAGINAL PESSARIES BETADINE* VAGINAL GEL

Presentation As vaginal pessaries each containing the Mundidone* brand of Povidone-Iodine USP 200 mg in a water-soluble base.

As vaginal gel containing the Mundidone* brand of Povidone-Iodine USP 10% w/w.

Both preparations are golden-brown in colour.

Uses Vaginitis due to candidal, trichomonal, non-specific or mixed infections, and pre-operative preparation of the vagina.

Dosage and administration Use throughout the menstrual cycle for two to four weeks.

Pessaries: Insert with applicator night and morning. Each pessary should be wetted with water immediately prior to insertion, thus ensuring maximum dispersion of the active constituent and avoiding risk of local irritation.

Gel: Insert an applicator full of gel (5 g) every night. The regimen may be varied to combine the use of the two

vaginal preparations or in combination with the Betadine* VC kit using one in the morning and one at night.

Contra-indications, warnings, etc If irritation, redness or swelling develop, discontinue use.

Patients with a history of iodine sensitivity should not use Betadine vaginal therapies without prior investigation.

These products are spermicidal and should not be used when conception is desired.

Pharmaceutical precautions Store in a cool dry place protected from light.

Legal category GSL.

Package quantities Pessaries; 28s with applicator.

Gel; 80 g with applicator.

Further information Betadine vaginal pessaries and vaginal gel are fungicidal, trichomonacidal and bactericidal to the pathogenic organisms which cause vaginitis. They retain their powerful germicidal effect in the presence of purulent exudate, blood, serum and necrotic tissue. The treatment does not cause stinging or staining in the vagina. The preparations are water soluble and the golden-brown colouration is easily removed by washing.

Product licence numbers

Pessaries 0337/5019

Gel 0337/5020

BETADINE* VC KIT

Presentation The Betadine VC kit consists of Betadine VC concentrate (containing the Mundidone* brand of Povidone-Iodine USP 10% w/v) 250 ml, with a plastic applicator bottle and vaginal applicator.

Uses As a vaginal cleanser in the treatment of vaginitis due to candidal, trichomonal, non-specific or mixed infections, and for pre-operative disinfection of the vagina.

Dosage and administration Once a day (preferably in the morning), for a fourteen-day period, including days of the menstrual cycle.

The Betadine VC concentrate should be diluted using the measuring cap on the concentrate bottle and used according to the patient instruction leaflet provided.

May be used in combination with Betadine vaginal pessaries or vaginal gel.

Contra-indications, warnings, etc Douching is not recommended in pregnancy.

If irritation, redness or swelling develop, discontinue use. Patients with a history of iodine sensitivity should not use Betadine VC kit without prior investigation.

This product is spermicidal and should not be used when conception is desired.

Pharmaceutical precautions Store in a cool dry place protected from light.

Legal category GSL.

Package quantities Carton containing bottle of 250 ml Betadine VC concentrate, an empty applicator squeeze bottle and a plastic vaginal applicator, with patient instruction leaflet.

Further information Betadine VC kit (antiseptic vaginal cleansing kit) is fungicidal, trichomonacidal,

bactericidal and virucidal. It retains its powerful germicidal effect in the presence of purulent exudate, blood, serum and necrotic tissue.

Product licence number 0337/5021.

BRADILAN* TABLETS

Presentation Enteric and white sugar coated tablets each containing tetranicotinoylfructose (nicofuranose) 250 mg.

Uses In peripheral vascular disease including primary and secondary Raynaud's disease, intermittent claudication, night cramps, perniois and cerebrovascular disease.

In hyperlipidaemia, i.e. hypertriglyceridaemia, hypercholesterolaemia, and lipid abnormalities associated with atherosclerosis.

Dosage and administration Dosage needs to be adjusted to the individual. An average dose of 2 tablets three times a day is often sufficient, but doses of 3-4 tablets three times a day may be indicated in some patients. It is better to start therapy with 2 tablets three times a day and increase this dosage over a period of days until the effects of vasodilation are appreciated by the patient and noticed by the doctor. If minimal facial flushing is well tolerated by the patient the dosage should be maintained at this level. However, the beneficial effects of therapy are not lost by reducing the dosage slightly until flushing disappears.

Contra-indications, warnings, etc Adjust daily dosage to suit each patient individually to ambient temperature.

Patients entering an overheated room or going into a warm bed should not take Bradilan tablets immediately before doing so or they may experience increased vasodilator effects.

The vasodilator effect of Bradilan tablets is enhanced by alcoholic beverages, but their concomitant consumption is not contra-indicated.

Because of the special structure of Bradilan tablets they should not be chewed or broken, but swallowed whole.

Bradilan tablets should not be given in the 24 hours before a surgical operation.

Overdosage: Large amounts of nicotinic acid may increase blood sugar levels, increase intestinal blood flow and skin temperature. Patients with diabetes, a history of ulceration and those susceptible to hyperthermia should have any such symptoms treated.

Pharmaceutical precautions Store in a well-closed container, in a cool dry place protected from light.

Legal category P.

Package quantities 50 and 250 tablets.

Further information With Bradilan tablet therapy a clinical response is observed within days.

Correct Bradilan tablet dosage and continued therapy do not result in continued facial flushing, headache, gastric irritation and nausea which are commonly associated with nicotinic acid and its salts. Because of its sustained therapeutic activity Bradilan tablets need be given only three to four times a day.

Product licence number 0337/5006.

BROVON* INHALANT SOLUTION

Presentation A solution for inhalation containing Atropine Methonitrate BP 0.14% w/v. Adrenaline BP 0.50% w/v and Papaverine Hydrochloride BP 0.88% w/v.

Uses For relief and prevention of bronchospasm in asthma, chronic bronchitis and other respiratory diseases.

Dosage and administration Twice-daily and once-nightly use will prevent attacks. No more than two puffs should be given within thirty minutes. In acute episodes more frequent use may be necessary. In order to ensure that Brovon inhalant solution is atomised to form sufficiently small particles the Brovon Midget Inhaler must be used. By briskly pressing and releasing the rubber bulb a fine mist is produced which is inhaled through the mouth.

Contra-indications, warnings, etc Should not be prescribed with monoamine oxidase inhibitors or with sympathomimetic drugs.

Contra-indicated in patients with hypertension, thyrotoxicosis, acute coronary disease and cardiac asthma.

Overdosage: Administer alpha-adrenergic blocker by intravenous injection and a beta blocker per os. Propranolol must not be given to asthmatics because of the risk of increasing bronchoconstriction.

Pharmaceutical precautions Store in cool dry place protected from light.

Legal category P.

Package quantities Bottles containing 20 ml and 50 ml.

Further information Nil.

Product licence number 0337/5009.

CARYLDERM* GEL SHAMPOO

Presentation A pleasantly perfumed clear yellow gel shampoo containing Carbaryl 1% w/v.

Uses Pediculocide for the treatment of head and pubic lice infestations.

Dosage and administration

The source of infestation should be sought and treated.

1. Wet the hair thoroughly with warm water. Squeeze about two inches of gel shampoo into the hand and rub all over the hair, paying special attention to the roots and the scalp.

2. Apply sufficient shampoo to ensure that no part of the scalp or hair is left uncovered, and work up into a rich lather.

3. Leave for at least five minutes, rinse thoroughly with clean, warm water, and repeat procedure.

4. Comb the hair while wet with a fine-toothed metal comb to remove lice and nits (this is only necessary for cosmetic reasons since the lice and nits are dead).

5. Shampooing may be repeated after seven to nine days.

For pubic lice: Wet hair, and apply shampoo directly to the pubic hair and the hair between the legs and around the anus, and leave for at least five minutes. Cover the skin and hair completely with the shampoo. Work up lather, and then rinse thoroughly. Repeat procedure and finally remove dead crab-lice with a suitable fine-toothed

comb. The shampoo may be used again if desired a week later.

Contra-indications, warnings, etc Children under the age of six months should be treated under medical supervision.

As with all shampoos avoid contact with the eyes.

When the insecticide is used by a school nurse or other health officer in the mass treatment of large numbers of children, it is advisable that protective plastic or rubber gloves be worn.

For external use only.

Overdosage: Empty stomach contents and keep patient warm. In the event of massive ingestion atropine in doses of 1 or 2 mg may be required to counteract cholinesterase inhibition.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Tube of 40 g.

Further information Carylderm gel shampoo contains an insecticide of the carbamate group which is lethal to both lice and their eggs (nits).

It has been shown that less resistance is likely to develop to carbaryl than to some other insecticides used for human infestations. Further, Carylderm gel shampoo has a residual action on the hair.

Product licence number 0337/0044.

CARYLDERM* LOTION

Presentation A clear, colourless alcohol based lotion containing Carbaryl 0.5% w/v.

Uses Pediculocide for the treatment of head and pubic lice infestations.

Dosage and administration

The source of infestation should be sought and treated.

For head lice:

1. Sprinkle the lotion on to dry hair. Rub gently into the scalp. Care should be taken to avoid contact with the eyes.
2. Repeat until hair is thoroughly moistened.
3. Allow to dry naturally – use no heat.
4. After 12 hours, shampoo the hair.
5. Rinse, and comb the hair while wet with a fine-toothed metal comb to remove lice and nits. (This is only necessary for cosmetic reasons, since the lice and nits are dead).
6. May be repeated after seven to nine days.

For pubic lice: The lotion should be applied locally to the pubic hair and the hair between the legs and around the anus and allowed to dry naturally. The lotion may be applied again if desired a week later. The method of application, dosage, etc. are as for the head.

Contra-indications, warnings, etc Children under the age of six months should be treated under medical supervision.

When treating pubic lice, mild stinging of a transient nature may be experienced associated with the antiseptic nature of the alcoholic lotion.

When Carylderm lotion is used by a school nurse or other health officer in the mass treatment of large numbers of children, it is advisable that protective plastic or rubber gloves be worn.

For external use only.

Contains flammable alcohol. Apply and dry with care. Avoid naked flames (e.g. coal, gas or electric fire) or lighted objects (e.g. matches, cigarettes or lighters).

Do not use artificial heat (e.g. electric driers).

Dry in a warm well-ventilated room.

Overdosage: As for ethyl alcohol. Empty stomach contents and keep patient warm. In the event of massive ingestion atropine in doses of 1 or 2 mg may be required to counteract cholinesterase inhibition.

Pharmaceutical precautions Store in a cool place, protected from light.

Legal category P.

Package quantities Sprinkler-top bottle of 55 ml.

Further information An alcoholic based lotion is considered to be the most effective way of administering a high concentration of insecticide to the hair. Carylderm lotion contains an insecticide of the carbamate group, which is rapidly lethal to both lice and their eggs (nits). It has been shown that less resistance is likely to develop to carbaryl than to some other insecticides used for human infestations. Further, Carylderm lotion has a residual action on the hair.

Product licence number 0337/0038.

CHOLEBRIN* TABLETS

Presentation White tablets each containing 500 mg iocetamic acid.

Uses For oral cholecystography and cholangiography.

Dosage and administration Six tablets 12–14 hours before X-ray examination. For visualisation of the biliary ducts, a further 6 tablets should be given three hours before examination.

Contra-indications, warnings, etc The administration of Cholebrin tablets is contra-indicated in patients with advanced hepatorenal disease, severe renal impairment, and in patients known to be allergic to iocetamic acid.

Overdosage: Monitor renal function. Treat gastro-intestinal effects symptomatically.

Pharmaceutical precautions Store in a cool, dry place protected from light.

Legal category P.

Package quantities Catch covers of 6 × 500 mg tablets.

Further information Nil.

Product licence number 0337/5900.

COMPLEMENT* CONTINUS* TABLETS

Presentation Bi-convex yellow tablets, embossed 'C' on one side and  on the other. Each tablet contains 100 mg Vitamin B₆ (Pyridoxine Hydrochloride) in NAPP Laboratories' patented controlled release system.

Uses Deficiency of Vitamin B₆ (Pyridoxine Hydrochloride) caused by usage of the oral contraceptive pill.

Dosage and administration One tablet to be taken daily, or at the discretion of the physician.

Contra-indications, warnings, etc None known.

Overdosage: Ingestion of twenty or more tablets may cause headache and will alter the kinetics of levodopa. No treatment is necessary.

Pharmaceutical precautions Comploment Continus tablets should be stored in a cool place, protected from light.

Legal category P.

Package quantities PVC/foil bubble packs containing 28 tablets.

Further information 50% of women who have symptoms of pessimism, anxiety, dissatisfaction, lethargy and loss of libido associated with the taking of the oral contraceptive pill have been reported to have an absolute deficiency of vitamin B₆ (Pyridoxine hydrochloride) (*Lancet* i, 897, 1973). Comploment Continus tablets will effectively correct such pyridoxine deficiencies. The controlled release system ensures adequate supplementation of the pyridoxine from a single tablet taken daily.

Product licence number 0337/0045.

CRADOCAP* SHAMPOO

Presentation An opaque white, pleasantly perfumed shampoo, contains Cetrimide BP 10% w/w.

Uses For the treatment of Cradle Cap or Scurf Cap in babies.

Dosage and administration

1. Wet the baby's head with a little warm water.
2. Squeeze out approximately $\frac{1}{2}$ to $\frac{3}{4}$ inch of Cradocap Shampoo on to the hand and rub gently into the baby's scalp.
3. Rinse off backwards, thus avoiding any possible contact with the baby's eyes.
4. Repeat instructions 2 and 3.
5. Dry the head gently with the baby's towel.

It is suggested that the treatment is carried out at twice weekly intervals until the condition clears.

Contra-indications, warnings, etc For external use only.

Pharmaceutical precautions Store in a cool dry place.

Legal category GSL.

Package quantities 36 g tube.

Further information Cradle Cap, or Scurf Cap as it is sometimes called, is a type of dandruff which frequently occurs during the first eighteen months of life. A safe and effective remedy is required. Cradocap is such a remedy.

Product licence number 0199/5005.

DIUMIDE*-K CONTINUS* TABLETS

Presentation White and orange film-coated bi-layered tablets, bi-convex in shape embossed DK on one side and (NAPP) on the other. Each tablet contains Frusemide BP 40 mg and Potassium Chloride 600 mg (8m Eq), the

latter incorporated within the patented controlled release system.

Uses Diumide-K Continus tablets are indicated in patients requiring diuresis and concomitant Potassium supplementation.

Indications include cardiac oedema, pulmonary oedema, hepatic oedema, renal oedema and peripheral oedema of various aetiologies.

Dosage and administration The usual adult dose is one tablet daily, normally in the morning. This may be adjusted depending on the condition.

N.B. The tablets should be swallowed whole, and not chewed so as not to destroy the controlled release system constituting the Potassium Chloride layer.

Diumide-K Continus tablets are not suitable for paediatric use.

Contra-indications, warnings, etc *Contra-indications:* Diumide-K Continus tablets are contra-indicated in hyperkalaemia, precomatose states associated with liver cirrhosis, Addison's disease and concomitant administration of Potassium sparing diuretics.

Warnings: Patients with prostatic hypertrophy or impairment of micturition have an increased risk of developing acute urinary retention.

Latent diabetes may become manifest or the insulin requirements of diabetic patients may increase.

Precautions: Care should be taken in patients being concurrently administered cardiac glycosides, hypotensive agents and cephaloridine. Care should also be exercised in patients with renal insufficiency where there is a risk of hyperkalaemia. Diumide-K Continus tablets should be administered with caution during the first trimester of pregnancy.

As with all medicines, Diumide-K Continus tablets should be kept out of the reach of children.

Side-effects: Frusemide is generally well tolerated and the patented Continus tablet ensures virtual absence of gastro-intestinal side-effects often associated with Potassium administration.

In rare instance of allergic reaction treatment should be discontinued. Hyperuricaemia may occur with Frusemide therapy. Bone marrow depression has also been reported as a rare complication and therapy should be withdrawn.

Overdosage: Treatment of overdosage should be aimed at fluid replacement and correction of the resulting electrolyte imbalance.

Pharmaceutical precautions Diumide-K Continus tablets should be stored in a cool dry place protected from light.

Legal category POM.

Package quantities 50 and 250 tablets.

Further information Frusemide produces a rapid and sustained diuresis which lasts for approximately four hours following administration. The potassium chloride content is released from the patented Continus tablet over a prolonged period ensuring maximum absorption, the avoidance of 'flushing out' of the potassium by the action of the diuretic, and virtual freedom from side-effects.

Product licence number 0337/0046.

ESODERM* LOTION

Presentation A clear colourless alcohol based lotion containing Gamma benzene hexachloride BP 1% w/v Dicophane BP 1% w/v.

Uses Pesticide for the treatment of lice and scabies.

Dosage and administration

For scabies:

1. Use dampened cotton wool to apply to all parts of the body except face and scalp.
2. Rub well in and allow to dry naturally.
3. In severe cases repeat on two or three successive days.
4. Use clean underclothing and bed linen after final treatment, and bath.

For head lice:

1. Sprinkle the lotion onto dry hair. Rub gently into the scalp. Care should be taken to avoid contact with the eyes.
2. Repeat until hair is thoroughly moistened.
3. Allow to dry naturally – use no heat.
4. After 12 hours, shampoo the hair.
5. Rinse, and comb the hair while wet with a fine-toothed metal comb to remove lice and nits.
6. Should be repeated after 7–9 days.

Contra-indications, warnings, etc Children under the age of six months should be treated under medical supervision.

When Esoderm lotion is used by a school nurse or other health officer in the mass treatment of large numbers of children, it is advisable that protective plastic or rubber gloves be worn.

Contains flammable alcohol. Apply and dry with care. Avoid naked flames (e.g. coal, gas or electric fire) or lighted objects (e.g. matches, cigarettes or lighters).

Do not use artificial heat (e.g. electric dryers).

Dry in a warm well-ventilated room.

For external use only.

Overdosage: As for ethyl alcohol, empty stomach contents and keep patient warm. In the event of massive ingestion diazepam or soluble barbiturates may be administered to control convulsions. Fat and oil should be avoided and adrenaline should not be given.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Sprinkler-top bottle of 55 ml.

Further information Gamma benzene hexachloride has a rapid action against *Sarcoptes Scabiei* and the alcoholic base aids penetration of burrows.

Product licence number 0199/5000.

ESODERM* SHAMPOO

Presentation Cream shampoo, cream in colour, containing: Gamma Benzene hexachloride BP 1% w/w, Dicophane BP 1% w/w.

Uses Pesticide for the treatment of lice infestation.

Dosage and administration

1. Soak the hair with hot water.
2. Massage 2 inches of shampoo into the scalp; leave two to three minutes.
3. Rinse with hot water.
4. Repeat (2) and work to lather.
5. Rinse thoroughly with hot water.

6. Comb hair with ordinary comb and then with a fine-toothed comb to remove all lice and nits.

7. Should be repeated after seven to nine days.

Contra-indications, warnings, etc Children under the age of six months should be treated under medical supervision.

When Esoderm shampoo is used by a school nurse or other health officer in the mass treatment of large numbers of children, it is advisable that protective plastic or rubber gloves be worn.

For external use only.

Overdosage: Empty stomach contents and keep patient warm. In the event of massive ingestion diazepam or soluble barbiturates may be administered to control convulsions. Fat and oil should be avoided and adrenaline should not be given.

Pharmaceutical precautions None.

Legal category P.

Package quantities Tube of 40 g. Jar of 300 g.

Further information Esoderm kills head lice. The content of Dicophane and gamma-hexachloride provides an effective pesticide combination.

Product licence number 0199/5001.

FERROCONTIN* CONTINUS* TABLETS

Presentation Red, film-coated, bi-convex, Continus tablets. Each tablet contains the equivalent of 100 mg Ferrous Iron in the form of Ferrous Glycine Sulphate within the patented controlled release system.

Uses Ferrocontin Continus tablets are indicated for the treatment and prophylaxis of iron deficiency anaemia.

Dosage and administration One tablet to be taken daily, or at the discretion of the physician. Ferrocontin Continus tablets should be swallowed whole and not chewed.

Contra-indications, warnings, etc As with all medicines keep out of the reach of children.

Overdosage: Inject Desferrioxamine 2 g intramuscularly. Lavage stomach with 1% sodium bicarbonate. Administer 5 g Desferrioxamine per os. Maintain fluid and electrolyte balance. The physician should be aware that Ferrous Glycine Sulphate will be released into the blood stream for a period of hours from tablets in the intestine.

Pharmaceutical precautions Store in a cool dry place protected from light.

Legal category P.

Package quantities 30 and 250 tablets.

Further information The amino acid-iron chelate Ferrous Glycine Sulphate prevents oxidation to the ferric form in the gastro-intestinal tract, thus enhancing absorption. The use of the patented controlled release system optimises the bioavailability of ferrous iron and minimises the likelihood of side-effects.

Product licence number 0337/0041.

FERROCONTIN* FOLIC CONTINUS* TABLETS

Presentation Pale orange, film-coated bi-convex Continus tablets. Each tablet contains the equivalent of

100 mg Ferrous Iron in the form of Ferrous Glycine Sulphate within the patented controlled release system and 0.5 mg Folic Acid BP.

Uses Ferrocontin Folic Continus tablets are indicated for the prophylaxis of iron and folic acid deficiencies during pregnancy.

Dosage and administration One tablet to be taken daily, or as directed by the physician. Ferrocontin Folic Continus tablets should be swallowed whole and not chewed.

Contra-indications, warnings, etc As with all medicines keep out of the reach of children.

Overdosage: Inject Desferrioxamine 2 g intramuscularly. Lavage stomach with 1% sodium bicarbonate. Administer 5 g Desferrioxamine per os. Maintain fluid and electrolyte balance. The physician should be aware that Ferrous Glycine Sulphate will be released into the blood stream for a period of hours from tablets in the intestine.

Pharmaceutical precautions Store in a cool dry place protected from light.

Legal category POM.

Package quantities 30 and 250 tablets.

Further information The amino acid-iron chelate Ferrous Glycine Sulphate prevents oxidation to the ferric form in the gastro-intestinal tract, thus enhancing absorption. The use of the patented controlled release system optimises the bioavailability of ferrous iron and minimises the likelihood of side-effects. The folic acid content of 1 tablet is unlikely to mask the presence of pernicious anaemia.

Product licence number 0337/0042.

K-CONTIN* CONTINUS* TABLETS

Presentation A pale orange, film-coated, controlled release tablet containing Potassium Chloride BP 600 mg.

Uses For potassium therapy and supplementation in patients on diuretic therapy, geriatric patients, chronic diarrhoea, prolonged use of laxatives and megaloblastic anaemia.

Dosage and administration One K-Contin Continus tablet with each diuretic tablet is the average prescribed dose, but this should be adjusted to individual patient's requirements. The range of recommended dosage is 2-5 K-Contin Continus tablets daily (approximately 16-40 mEq K⁺) or on alternate days if diuretic therapy has been so prescribed. The tablets should be swallowed whole and not chewed.

Contra-indications, warnings, etc In patients with advanced renal failure, hyperkalaemia may develop if K-Contin Continus tablets are given injudiciously.

Signs or symptoms which may indicate ulceration or obstruction of the small bowel in patients taking tablets or capsules containing potassium salts are indications for stopping the treatment with potassium preparations.

Overdosage: Empty stomach contents. Treat mild to moderate hyperkalaemia with sodium polystyrene sulphate by mouth. Severe hyperkalaemia requires electrocardiogram monitoring and calcium gluconate i.v. injection (10 to 30 ml). The physician should be aware that potassium chloride will be released into the blood stream for a period of hours from tablets in the intestine.

Pharmaceutical precautions Store in a well-closed container, in a cool dry place protected from light.

Legal category P.

Package quantities Containers of 500 and 5,000 tablets.

Further information It is well recognised that potassium chloride is the correct salt for all patients who require potassium therapy. The K-Contin Continus tablet permits gradual release of the potassium chloride into the gut physiologically and continuously for 10-12 hours. The release mechanism is dependent on the physical structure of the K-Contin Continus tablet and does not depend on the pH of the gut.

Product licence number 0337/0025.

MORHULIN* OINTMENT

Presentation A white ointment containing in a paraffin and lanolin base:

Cod liver oil BP	11.4% w/w
Zinc oxide BP	38.0% w/w

Uses Treatment of varicose ulcers, pressure sores and minor wounds.

Dosage and administration Spread thinly on gauze to cover affected area and about one inch of surrounding skin; on clean wounds dressing may remain for three days. If discharging wound, change dressing daily.

Contra-indications, warnings, etc None.

Pharmaceutical precautions None.

Legal category GSL.

Package quantities Tube of 50 g. Container of 350 g.

Further information Morhulin is non-irritating, non-sensitising with negligible odour and keeps its consistency at body temperature.

Product licence number 0199/5012.

MORSEP*

Presentation A white cream containing:

Cetrimide BP	0.5% w/w
Vitamin A	70 i.u. per g
Vitamin D ₂	10 i.u. per g

Uses A cream for the treatment of urinary ammonia dermatitis.

Dosage and administration Wash affected area and surrounding skin; gently dry; apply Morsep paying particular attention to the creases in the skin. For protection from napkin rash, repeat at each napkin change.

Contra-indications, warnings, etc None.

Pharmaceutical precautions None.

Legal category GSL.

Package quantities Tube of 40 g. Container of 300 g.

Further information Morsep's dual action relieves soreness and irritation and promotes healing.

Product licence number 0199/5014.

MST* CONTINUS* TABLETS

Presentation MST Continus tablets 10 mg are golden brown, film-coated and bi-convex. Each tablet contains 10 mg of Morphine Sulphate BP incorporated within the patented controlled release system. The tablets are marked  on one side and 10 mg on the other side.

MST Continus tablets 30 mg are dark purple, film coated and bi-convex. Each tablet contains 30 mg of Morphine Sulphate BP incorporated within the patented controlled release system. The tablets are marked  on one side and 30 mg on the other.

Uses MST Continus tablets are indicated for the prolonged relief of severe and intractable pain.

Dosage and administration MST Continus should be used twice daily. The dosage is dependent upon the severity of the pain and the patient's previous history of analgesic therapy.

A patient initially presenting with severe and intractable pain will normally be started on a dosage of one or two MST Continus tablets 10 mg twice daily. Increases in pain or tolerance to the drug will require increases in dosage using MST Continus tablets 10 mg and 30 mg alone or in combination.

A patient transferred from other oral preparations should normally receive the same total twenty four hour morphine dosage divided between the morning and evening administration.

Patients receiving MST Continus tablets in place of parenteral morphine should be given a sufficiently increased dosage to compensate for the reduction in analgesic effects associated with orally administered analgesics.

MST Continus tablets should be swallowed whole and not chewed.

Contra-indications, warnings, etc *Contra-indications:* Respiratory depression, obstructive airways disease. Concurrent administration of monoamine oxidase inhibitors or within two weeks of discontinuation of treatment with them. MST Continus tablets are not recommended for paediatric use or for use in pregnancy.

Precautions: As with all narcotics a reduction in dosage may be advisable in the elderly, in hypothyroidism, and chronic hepatic disease.

Warnings and adverse effects: Tolerance and dependence may occur. MST Continus tablets can be readily combined with the phenothiazines but it should be noted that morphine potentiates the effects of tranquillisers, anaesthetics, hypnotics and sedatives.

Nausea and vomiting may be troublesome (Vide Infra).

Pharmaceutical precautions MST Continus tablets should be stored in a cool, dry place protected from light.

Legal category POM, MDA.

Package quantities

10 mg: pack of 50 tablets.

30 mg: pack of 50 tablets.

Further information Morphine Sulphate BP is readily absorbed from the gastro-intestinal tract following oral administration. The patented controlled release system maintains plasma levels of Morphine over a period of up to twelve hours and reduces the likelihood of Morphine associated side-effects.

Product licence numbers

10 mg 0337/0055.

30 mg 0337/0059.

NITROCONTIN* CONTINUS* TABLETS

Presentation Nitrocontin Continus tablets 2.6 mg are flat, bevelled, pink, controlled release tablets containing Nitroglycerin BP 2.6 mg and embossed NC on one side and with the logo  on the other.

Nitrocontin Continus tablets 6.4 mg are flat, bevelled, pink controlled release tablets containing Nitroglycerin BP 6.4 mg and embossed  on one side and with the logo  on the other.

Uses For the prophylaxis and continued treatment of angina pectoris, whether or not associated with previous history of myocardial infarction. Nitrocontin Continus tablets are indicated in all cases in which sublingual nitroglycerin has provided temporary relief, whether these be cases of classical angina pectoris or the anginal pain subsequent to myocardial infarction.

Dosage and administration The tablets must be swallowed whole. Dosage should always be adjusted according to the response obtained by the individual patient and the severity of the anginal pain. Initially, the recommended dosage is one 2.6 mg tablet morning and evening.

If the symptoms have not been adequately controlled after a week on this regimen, the dosage should be increased to one 6.4 mg tablet morning and evening.

An increase in dosage to 6.4 mg three times daily may be found necessary in severe cases of angina pectoris which have not fully responded to the lesser recommended dosage.

Contra-indications, warnings, etc *Contra-indications:* As with all nitrites, cerebral haemorrhage and brain trauma, incipient glaucoma.

Side-effects: An infrequent side-effect of a transient nature which occurs with all nitrite administration is 'nitrite headache'. This disappears with continued treatment. Although patients develop tolerance to this symptom they do not develop tolerance to the drug. However, such side-effects are virtually absent or substantially diminished with Nitrocontin Continus tablet therapy due to the patented controlled release system.

Overdosage: Empty stomach contents. Administer oxygen if necessary. Treat methaemoglobinemia with intravenous methylene blue. Keep unconscious patients horizontal and lower head. Physicians should be aware that tablets in the intestine will release nitroglycerin for a period of hours.

Pharmaceutical precautions Store in a cool dry place protected from light.

Legal category P.

Package quantities Tablets 2.6 mg: 100 tablets.

Tablets 6.4 mg: 100 tablets.

Further information Nitroglycerin has a twofold action in relieving angina pectoris. It reduces cardiac work and dilates the coronary arteries. Thus, not only is the arterial oxygen requirement of the myocardium lessened, but the amount of oxygenated blood reaching the ischaemic heart is increased.

Nitrocontin Continus tablets provide adequate and

continuous nitroglycerin activity throughout the day and night on a simple b.d. dosage.

The need for sublingual nitroglycerin is substantially reduced as the frequency and severity of anginal attacks are decreased.

Nitrocontin Continus tablets may be co-prescribed with β -blocking agents for enhanced prophylaxis from angina. Nitrocontin Continus tablets actively prevent anginal episodes and reduce heavy dependence on multiple doses of sublingual nitroglycerin administration.

Product licence numbers

Tablets 2.6 mg 0337/5026

Tablets 6.4 mg 0337/5027

OTOSEPTIL* EAR DROPS

Presentation ear drops containing neomycin undecylate (equivalent to neomycin 0.67 mg per ml), tyrothricin (gramicidin and tyrocidin) 1.0 mg per ml, hydrocortisone 1.0 mg per ml and ethylene oxidepolyoxypropylene glycol condensate 10 mg per ml.

Uses Acute and chronic otitis externa including bacterial and fungal infections. Eczematous or seborrhoeic dermatitis of the external auditory meatus. As an adjunctive topical therapy in chronic otitis media, and post-operatively for mastoid cavities and after fenestration operations.

Dosage and administration *Adults, children and infants:* Instil 3–5 drops with the aid of the dropper supplied. A cotton-wool plug well moistened with the ear drops may be inserted if required. Repeat four times a day until relief is obtained. Alternatively, a gauze wick may be inserted and kept moist by the application of the drops four times daily.

Contra-indications, warnings, etc

Contra-indications: Infections caused by insensitive organisms and viral ear infections.

Precautions: The use of antibiotic/corticosteroid ear drops occasionally results in the overgrowth of a non-sensitive organism and signs of inflammation may be suppressed by the corticosteroid. If superinfection occurs the treatment should be stopped and appropriate treatment instituted.

Pharmaceutical precautions Store at 4°C.

Legal category POM.

Package quantities Bottles of 8 ml with separate dropper.

Further information Otoseptil ear drops are antibacterial, anti-fungal and anti-inflammatory. The anti-fungal activity is important since some 20% of cases of otitis externa are primarily of fungal or mixed fungal and bacterial aetiology.

Product licence number 0337/5025.

PHYLLOCONTIN* CONTINUS* TABLETS

Presentation Pale yellow, film-coated tablets with 'SA' on one side and  on the other. Each tablet contains aminophylline 225 mg in the patented controlled release system.

Uses For the treatment and prophylaxis of bronchospasm associated with asthma, emphysema and chronic

bronchitis. Phyllocontin Continus tablets are also indicated in the treatment of cardiac asthma and left ventricular or congestive cardiac failure.

Dosage and administration The usual daily dose is 2 tablets twice a day, taken morning and evening, following an initial week of therapy on 1 tablet twice daily.

Since patients vary in their response to Xanthines, the dosage must be titrated individually, and if maximum response is not achieved, Theophylline plasma levels should be measured. Smoking and consumption of alcohol may increase clearance of Theophylline and therefore, the dosage requirement. While the usual dose is 2 tablets twice daily, factors such as viral infections, liver disease and heart failure, may reduce clearance of Theophylline, and the dosage should be reduced if necessary. A reduction in dosage may be necessary in the elderly patient.

N.B. Tablets should be swallowed whole and not chewed.

Contra-indications, warnings, etc None.

Overdosage: Empty stomach contents. Monitor electrocardiogram and maintain fluid balance. Oral activated charcoal has been found to reduce high theophylline blood levels. In severe poisoning employ charcoal-column haemoperfusion. Treat symptoms on appearance. The physician should be aware that tablets in the intestine will continue to release aminophylline for a period of hours.

Side-effects: The risk of side-effects usually associated with aminophylline and xanthine derivatives such as nausea, gastric irritation, headache and CNS stimulation are absent or much diminished when Phyllocontin Continus tablets are given.

Pharmaceutical precautions Store in a cool, dry place protected from light.

Legal category P.

Package quantities 50 and 250 tablets.

Further information Phyllocontin Continus tablets utilise the patented controlled release mechanism, in which aminophylline is released to give an effective therapeutic blood level, lasting up to 12 hours. This release mechanism therefore minimises the unpleasant side-effects usually associated with oral doses of aminophylline, e.g. nausea and gastric irritation.

Product licence number 0337/0026.

PHYLLOCONTIN* PAEDIATRIC CONTINUS* TABLETS

Presentation Pale orange bi-convex tablets with SA/2 on one side and  on the other. Each tablet contains Aminophylline BP 100 mg in the patented controlled release system.

Uses For the treatment and prophylaxis of childhood bronchospasm associated with asthma, bronchitis and emphysema.

Dosage and administration The recommended paediatric doses are as follows:

Age 4–8 years (approx. weight 15–24 kgs or 34–53 lb): 1 tablet twice a day, taken morning and evening.

Age 8–12 years (approx. weight 24–35 kgs or 53–77 lb): 1 or 2 tablets twice a day.

Conventional oral aminophylline doses in children range from 12–20 mg/kg/24 hours. Some children with chronic asthma require and tolerate much higher doses (25–42 mg/kg/24 hours). The above dosages will therefore depend on the patient's clinical response.

For night-long prophylaxis of bronchospasm, the dosage is 1 Phyllocontin paediatric tablet on going to bed, increased to 2 tablets if necessary.

N.B. The tablets should be swallowed whole and not chewed so as not to destroy the controlled release system constituting the tablet structure.

Contra-indications, warnings, etc Should not be given concomitantly with ephedrine.

Overdosage: Empty stomach contents. Monitor electrocardiogram and maintain fluid balance. Oral activated medical charcoal has been found to reduce high theophylline blood levels. In severe poisoning employ charcoal-column haemoperfusion. Treat symptoms on appearance. The physician should be aware that tablets in the intestine will continue to release aminophylline for a period of hours.

Side-effects: The risks of side-effects usually associated with Aminophylline and Xanthine derivatives such as nausea, gastric irritation, headache and CNS stimulation are absent or much diminished when Phyllocontin Paediatric Continus tablets are given.

Pharmaceutical precautions Store in a cool, dry place protected from light.

Legal category P.

Package quantities 50 and 250 tablets.

Further information Phyllocontin Paediatric Continus tablets utilise the controlled release mechanism, in which Aminophylline is released to give an effective therapeutic blood level, lasting up to 12 hours from a single dose, thus enabling 24 hour prophylaxis on a simple b.d. dosage. The controlled release mechanism minimises the risk of unpleasant side-effects usually associated with oral doses of Aminophylline, e.g. nausea and gastric irritation. Phyllocontin Paediatric Continus tablets are ideal for night long prophylaxis of bronchospasm where Aminophylline therapy is indicated.

Product licence number 0337/0040.

PLESMET* SYRUP

Presentation Blackcurrant flavoured syrup containing the equivalent of 25 mg ferrous iron per 5 ml dose in the form of ferrous glycine sulphate.

Uses Treatment of iron deficiency anaemia in infants, adolescents and adults.

Dosage and administration *Adults:* 5–10 ml three times a day.

Children: 2–5 ml two or three times per day according to age (when necessary Plesmet syrup may be diluted with Syrup Tolu BP to make up a 5 ml dose).

Contra-indications, warnings, etc None.

Pharmaceutical precautions None.

Legal category P.

Package quantities Bottles of 100 ml and 1 litre.

Further information Chelated iron is more readily absorbed and utilised than the more conventional forms of iron. Side effects are virtually absent.

Product licence number 0191/5002

PRESSURISED BROVON* INHALER

Presentation A green, transparent, shatterproof aerosol for inhalation containing Adrenaline BP 0.50% w/v and Atropine Methonitrate BP 0.10% w/v in a freon-alcoholic propellant solution.

Uses For the relief and prevention of bronchospasm in asthma, chronic bronchitis and other respiratory diseases.

Dosage and administration Having removed the dust cap, the unit is held upright, the mouthpiece inserted between the lips, the adaptor is depressed and at the same time the patient inhales deeply. The breath is held for a moment, then the patient slowly exhales, releasing the adaptor at the same time. Each depression releases a consistently accurate measured dose of Pressurised Brovon inhalant containing adrenaline 0.25 mg and atropine 0.05 mg. Approximately 330 doses are obtained from each aerosol.

One 'puff' of Pressurised Brovon inhaler may be used four to six-hourly to prevent attacks. In an acute attack one or two puffs should suffice, repeated if necessary, not more often than every 30 minutes.

Contra-indications, warnings, etc Should not be prescribed with monoamine oxidase inhibitors or with sympathomimetic drugs.

Contra-indicated in patients with hypertension, thyrotoxicosis, acute coronary disease and cardiac asthma.

Overdosage may produce transitory tachycardia or dizziness. As with all atropine-containing preparations dryness of the mouth may occur.

It is highly inadvisable to exceed the recommended dose.

Overdosage: Administer alpha-adrenergic blocker by intravenous injection and a beta-blocker per os. Propranolol must not be given to asthmatics because of the risk of increasing broncho-constriction.

Pharmaceutical precautions Store in a cool, dry area protected from light.

Legal category POM.

Package quantities Aerosol of 17 ml.

Further information The rapid sympathomimetic action of the adrenaline and the less rapid but more prolonged parasympatholytic action of the atropine methonitrate, are both complementary and mutually enhancing in relaxing bronchospasm.

Product licence number 0337/5011.

PRESSURISED ISO-BROVON* INHALER PRESSURISED ISO-BROVON* PLUS INHALER

Presentation A green, transparent, shatterproof aerosol for inhalation containing Isoprenaline Hydrochloride USP 0.35% w/v and Atropine Methonitrate BP 0.10% w/v in a freon/alcohol propellant solution.

The PIB Plus inhaler contains Isoprenaline Hydrochloride USP 1.00% w/v and Atropine Methonitrate BP 0.10% w/v in a freon/alcoholic propellant solution.

Uses For the relief and prevention of bronchospasm in asthma, chronic bronchitis and other respiratory diseases.

Dosage and administration Having removed the dust cap the unit is held upright, the mouthpiece inserted between the lips, the adaptor is depressed and at the same time the patient inhales deeply. The breath is held for a moment, then the patient slowly exhales, releasing the adaptor at the same time. Each depression releases a consistently accurate measured dose of PIB inhalant. Approximately 330 doses are obtained from each aerosol.

The PIB inhalers may be used four- to six-hourly to prevent attacks. In an acute attack one or two 'puffs' should suffice, repeated if necessary, not more often than every 30 minutes.

Contra-indications, warnings, etc Should not be prescribed with monoamine oxidase inhibitors or with sympathomimetic drugs.

Overdosage may produce transitory tachycardia or dizziness. As with all atropine-containing preparations dryness of the mouth may occur.

Contra-indicated in patients with hypertension, thyrotoxicosis, acute coronary disease and cardiac asthma.

It is highly inadvisable to exceed the recommended dose.

Overdosage: Administer alpha adrenergic blocker by intravenous injection and a beta blocker per os. Propranolol must not be given to asthmatics because of the risk of increasing bronchoconstriction.

Pharmaceutical precautions Store in a cool dry place protected from light.

Legal category POM.

Package quantities Aerosol of 17 ml.

Further information Nil.

PIB 0337/5012

PIB Plus 0337/5010

PRIODERM* CREAM SHAMPOO

Presentation A light-orange pearlescent cream shampoo containing malathion 1.0% w/w.

Uses Pesticide for the treatment of head and pubic lice.

Dosage and administration The source of infestation should be sought and treated.

For head lice: Wet hair thoroughly with warm water, squeeze about 2 inches of the cream shampoo into the hand and rub all over the hair, paying special attention to the roots and the scalp. Apply sufficient shampoo to ensure no part of the scalp or hair is left uncovered and work into a lather.

Leave for four or five minutes, rinse thoroughly with clean water, and repeat the procedure. Comb the hair while wet with a fine-toothed metal comb to remove lice and nits. (This is only necessary for cosmetic reasons since the lice and nits are dead.) May be repeated after seven to nine days.

For pubic lice: Wet area, and apply shampoo directly to the pubic hair and the hair between the legs and around the anus, and leave for at least five minutes. Cover the skin and hair completely with the shampoo.

Work up a lather, and then rinse thoroughly. Repeat

procedure, and finally remove dead crab-lice with a suitable fine-toothed comb.

Contra-indications, warnings, etc Children under the age of 6 months should be treated under medical supervision.

As with all shampoos, avoid contact with the eyes. When Prioderm cream shampoo is used by a school nurse or other health officer in the mass treatment of large numbers of children, it is advisable that gloves be worn.

For external use only.

Overdosage: Empty stomach contents and keep patient warm. In the event of massive ingestion atropine and pralidoxime may be required to counteract cholinesterase inhibition.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Tube of 40 g.

Further information Prioderm cream shampoo is lethal to both lice and their eggs.

Product licence number 0337/0036.

PRIODERM* LOTION

Presentation A clear colourless alcohol based lotion containing Malathion 0.5 w/v.

Uses A pesticide for the treatment of head lice, pubic lice and scabies.

Dosage and administration The source of infestation should be sought and treated.

For head lice:

1. Sprinkle the lotion on the hair. Rub gently into the scalp. Care should be taken to avoid the eyes.
2. Repeat until the scalp is thoroughly moistened.
3. Allow to dry naturally – use no heat.
4. After 12 hours shampoo the hair.
5. Rinse and comb the hair while wet with a fine-toothed metal comb to remove lice and nits (this is only necessary for cosmetic reasons, since the lice and nits are dead).
6. May be repeated after seven to nine days.

For pubic lice: The lotion should be applied locally to the pubic hair and the hair between the legs and around the anus. The method of application, dosage etc. are as for the head.

For scabies:

1. Use dampened cotton wool to apply to all parts of the body except face and scalp.
2. Rub well in and allow to dry naturally.
3. Use clean bed linen and underclothes after final treatment. Do not bathe until twelve hours after treatment.

Contra-indications, warnings, etc Contains flammable alcohol. Apply and dry with care. Avoid naked flames (e.g. coal, gas or electric fire) or lighted objects (e.g. matches, cigarettes or lighters).

Do not use artificial heat (e.g. electric dryers).

Dry in a warm well-ventilated room.

Children under the age of 6 months should be treated under medical supervision.

When treating pubic lice, mild stinging of a transient nature may be experienced associated with the antiseptic nature of the alcoholic lotion.

When Prioderm lotion is used by a school nurse or other health officer in the mass treatment of large numbers of children, it is advisable that protective plastic or rubber gloves be worn.

For external use only.

Overdosage: As for ethyl alcohol, empty stomach contents and keep patient warm. In the event of massive ingestion atropine and pralidoxime may be required to counteract cholinesterase inhibition.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities Sprinkler-top bottle of 55 ml.

Further information Prioderm lotion is rapidly lethal to both the lice and eggs and affords several weeks' protection.

The volatile alcoholic base evaporates to dryness within one hour leaving a high concentration of malathion on the hair.

Product licence number 0199/5002.

SEDONAN* EAR DROPS

Presentation Eardrops containing phenazone BPC 5% w/w and chlorbutol 1% w/w in anhydrous glycerin.

Uses For the relief of pain due to acute and chronic otitis media, otitis externa (acute and chronic), furuncles, boils and inflammation of the external auditory canal.

Dosage and administration Instil 4–5 drops with the aid of the dropper into the external auditory canal, and plug with cotton wool. Repeat as required. It is not necessary to warm the drops.

Contra-indications, warnings, etc The action of Sedonan ear drops is purely analgesic and where middle ear infection is present, it is a useful adjuvant to antibiotic therapy.

Pharmaceutical precautions Store in a cool dry place protected from light.

Legal category P.

Package quantities Bottle containing 8 ml with separate dropper.

Further information Nil.

Product licence number 0337/5008.

TEEJEL* GEL (MOORE'S*)

Presentation A colourless, analgesic, antimicrobial gel for topical application containing the Mundisal* brand of choline salicylate 8.7% w/w and cetyltrimethylbenzylammonium chloride 0.01% w/w in a vehicle formulated to enhance the therapeutic effect.

Uses Relief of pain and infection in and around the mouth in oral ulcers, including aphthous, traumatic and herpetic. Infant teething and denture chafing. Painful stomatitis, gingivitis and glossitis.

Dosage and administration *Adults:* Using a clean finger massage approximately half an inch of Teejel gel onto the tender, painful area. The gel may be applied every three to four hours as required.

Children: (from 4 months to 2 years): Using a clean finger, massage approximately a quarter of an inch of the Teejel gel onto the affected area. The gel may be applied every three to four hours as required.

Contra-indications, warnings, etc Contra-indicated in salicylate sensitivity.

Pharmaceutical precautions Store in a cool, dry place.

Legal category GSL.

Package quantities Sealed tubes containing 10 g.

Further information Nil.

Product licence number 0337/5016.

TRILISATE* TABLETS

Presentation Pale orange, capsule shaped, scored tablets containing 500 mg salicylate as Choline Magnesium Trisalicylate. The tablets embossed 'NAPP 500' on one side and 'TRILISATE' on the reverse.

Uses Trilise tablets are indicated for relief of the signs and symptoms of rheumatoid arthritis, osteoarthritis and other arthroses.

Dosage and administration Two tablets twice a day for osteoarthritis and mild to moderate arthroses. Three tablets twice a day for rheumatoid arthritis and the more severe arthroses.

Contra-indications, warnings, etc *Contra-indications:* Hypersensitivity to aspirin. Active peptic ulceration. Haemophilia.

Precautions: Concurrent administration with other analgesics containing aspirin. As with other salicylate, Trilise tablets should be used with caution in patients with chronic renal insufficiency, or with erosive gastritis or peptic ulcer.

Trilise tablets should be used with caution in pregnancy.

Warnings and adverse effects: May induce gastrointestinal haemorrhage. Reports indicate that when salicylates are given with steroids, the butazones or alcohol, the risk of gastrointestinal ulceration is increased.

Trilise tablets are not recommended for children under twelve years of age. As with all medicines, Trilise tablets should be kept out of reach of children.

Overdosage: Empty stomach contents and lavage stomach with 5% sodium bicarbonate solution. Severe overdosage should be treated by diuresis induced by intravenous saline with sodium bicarbonate, or dextrose solution. Electrolyte levels and acid base balance should be monitored and corrected as necessary.

Pharmaceutical precautions Trilise tablets should be stored in a cool, dry place, protected from light.

Legal category P.

Package quantities Containers of 60 tablets.

Further information When Trilise tablets are administered, the salicylate is absorbed rapidly and reaches peak blood levels within two hours. At recommended doses, the therapeutic range of 5 to 30 mg/100 ml is achieved, and a steady state condition is normally reached after 4–5 doses.

Trilise tablets do not cause any significant faecal blood loss nor do they affect platelet aggregation.

Trilistate tablets do not cause any observable stomach mucosal irritation as determined by endoscopic examination.

Product licence number 0337/0053.

XERUMENEX* EAR DROPS

Presentation Ear drops containing triethanolamine polypeptide oleate condensate 10% w/w.

Uses Routine removal of excessive or impacted wax. Removal of wax to facilitate inspection of the tympanum or audiometry.

Dosage and administration With head tilted to the side at 45° angle fill ear canal with drops. Insert cotton wool plug soaked in Xerumenex and allow the drops to remain in the ear for 15–30 minutes. The drops should not be allowed to remain in the ear longer. Then gently flush or wash the ear with lukewarm water, using a soft rubber syringe and avoiding excessive pressure. If a second application is necessary, in unusually hard impactions, the procedure may be repeated.

Contra-indications, warnings, etc Use with care in presence of perforated ear drum.

Patients using Xerumenex at home should be instructed never to attempt to remove wax themselves by the insertion of objects such as matchsticks and hairpins, nor to leave the drops in for longer than 15–30 minutes.

On rare occasions patients who misuse the drops and leave them in longer than advised develop a localised skin reaction.

Pharmaceutical precautions Store in a cool, dry place protected from light.

Legal category P.

Package quantities Bottle of 8 ml with separate dropper.

Further information Nil.

Product licence number 0337/5007.

X-PREP* LIQUID

Presentation A chocolate-flavoured brown liquid purgative containing purified, standardised extract of senna fruit equivalent to 142 mg Sennosides A and B in each 71 ml dose.

Uses A single-dose pre-radiographic purgative given the day prior to radiographic examination, particularly in gastro-intestinal and urological procedures.

Dosage and administration *Adults:* The contents of a complete bottle, 71 ml should be taken between 2 and 4 pm on the day prior to X-ray examination. This should be followed by at least a tumbler full of water.

Children (under 14 years) and frail underweight patients: The dosage is 1 ml per kg body weight taken between 2 and 4 pm on the day before the examination. The dosage may be split into equal volumes with one hour between each administration. Each administration should be followed by a tumbler full of water. Patients should be advised to expect a strong, thorough bowel action to begin approximately six to eight hours later.

Contra-indications, warnings, etc Mild to severe griping and some nausea occur occasionally, as with all purgatives; however, these are generally less of a problem with X-Prep liquid.

A light, bland, fat-free meal should precede administration. No solid food should be taken after administration and nothing at all after 10 pm on the day prior to X-ray examination.

In diabetic patients, the doctor should be aware of the sugar content of X-Prep liquid (46.86 g per 71 ml dose).

The usual clinical contra-indications for purgatives apply to X-Prep liquid.

Pharmaceutical precautions Store in a cool dry place protected from light.

Legal category P.

Package quantities Bottles containing 71 ml.

Further information Nil.

Product licence number 0337/5017.

**Trade Mark*

ALBUCID* EYE DROPS
ALBUCID* EYE OINTMENT

Presentation Albucid Eye Drops contain 10%, 20% and 30% sulphacetamide sodium pH adjusted. Sodium pentachlorophenate, 0.01%, is included as a preservative.

Albucid Eye Ointment contains 2½% and 6% sulphacetamide sodium pH adjusted in a greasy base and 10% sulphacetamide sodium pH adjusted in a water-miscible base.

Uses *Albucid Eye Drops: Albucid Eye Drops 10%:* Mild infections of the conjunctiva and eyelids.

Industrial eye injuries. Prophylaxis against infection.

Albucid Eye Drops 20%: Conjunctivitis and ophthalmia neonatorum.

Albucid Eye Drops 30%: Severe conjunctivitis. Corneal ulceration including dendritic ulceration. Trachoma.

Albucid Eye Ointment: Albucid Eye Ointment 2½%: Mild infections of the conjunctiva and eyelids. Industrial eye injuries. Prophylaxis against infection.

Albucid Eye Ointment 6%: Conjunctivitis. Trachoma. Corneal ulceration including dendritic ulceration.

Albucid Eye Ointment 10%: Blepharitis and styes.

Dosage and administration *Albucid Eye Drops:* Adults and children: 2–4 drops two to six hourly.

Albucid Eye Ointment: Adults and children: 2½% and 6% at night. 10% apply to lids two to four times daily.

Contra-indications, warnings, etc Known sensitivity to sulphonamides.

Side-effects: Some transient irritation may occur, especially with the higher concentrations.

Pharmaceutical precautions Store at room temperature. Do not freeze.

Legal category POM.

Package quantities *Albucid Eye Drops (all strengths):* Opaque white polythene bottles with coloured caps, containing 10 ml sterile solution. Colour coding of caps:

10% drops – green

20% drops – brown

30% drops – red

Albucid Eye Ointment (all strengths): 4 g tube sterile.

Further information Nil.

Product licence numbers

ALGESAL*

Presentation Off-white, lavender-scented cream containing diethylamine salicylate 10% w/w in a vanishing cream base.

Uses Analgesic balm for use in neuralgia, fibrositis, lumbago, sciatica. Pain in muscles, joints and soft tissues due to rheumatism, injury and over-use.

Dosage and administration Algesal should be massaged over the whole of the affected area until the cream has been fully absorbed and the skin is dry. This may be repeated several times a day as often as the pain demands. If the skin is too tender for massage in conditions such as cellulitis, Algesal may be applied as a liberal dressing on lint or gauze.

Contra-indications, warnings, etc Algesal should not be used if the surface of the skin is broken.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Collapsible tubes of 40 g.

Further information Nil.

Product licence number 1752/5000.

ASMAPAX* TABLETS

Presentation Buff-coloured round, bevelled tablet with 'Asmapax' and 'N' on one side and bisecting line on the obverse. Each tablet contains:

Ephedrine resinate (equivalent to	
Ephedrine Hydrochloride BP 50 mg)	123 mg
Theophylline Hydrate BP	65 mg

Uses Prolonged action bronchodilator.

Relief of bronchospasm in chronic bronchitis asthma and similar disorders.

Dosage and administration *Adults:* 1–2 tablets two or three times a day.

Children 5–12 years: ½ tablet two or three times a day, or as directed.

Contra-indications, warnings, etc A known sensitivity to ephedrine is the only absolute contra-indication, but Asmapax should be used with caution in patients with cardiac conditions, hypertension, hyperthyroidism or prostatic enlargement. Like all sympathomimetic amines, ephedrine should not be used in conjunction with monoamine oxidase inhibitors.

The recognised central stimulatory effects and occasional urinary retention caused by ephedrine are rare, due to the sustained release that resination of ephedrine produces.

In cases of overdosage, gastric lavage should be undertaken, followed by mild sedation.

Pharmaceutical precautions Nil.

Legal category POM.

Package quantities Containers of 30 and 250 tablets.

Further information Nil.

Product licence number 0188/5920.

CLARADIN*

Presentation Round white bevelled edge tablets with a breakline. Each tablet contains aspirin 300 mg in an effervescent base.

Uses Analgesic and antipyretic at recommended dosage. For conditions where a truly soluble aspirin tablet will provide the most effective and acceptable treatment, i.e. relief of mild to moderate pain and/or reduction of fever associated with upper respiratory tract infections and painful or febrile disorders, such as influenza, pyrexia, neuralgia, rheumatic pain, dysmenorrhoea, migraine pain.

Dosage and administration *Adults:* 2–3 tablets every four hours. Do not exceed 13 tablets in 24 hours unless so directed.

Children: 4–6 years: $\frac{1}{2}$ tablet every four hours.

6–12 years: 1 tablet every four hours. Do not exceed 4 tablets (4–6 years) or 8 tablets (6–12 years) in 24 hours unless directed.

Discard remainder of tablet which will deteriorate once removed from foil.

Claradin Tablets should be allowed to dissolve completely in half a glass of water before administration.

Contra-indications, warnings, etc

Contra-indications: Active peptic ulceration. Haemophilia. Hypersensitivity.

Use in pregnancy: There is clinical or epidemiological evidence of safety in human pregnancy.

Precautions: Aspirin may prolong labour and contribute to maternal and neonatal bleeding, and is best avoided at term. May enhance the effects of anti-coagulants. May inhibit action of uricosurics. May precipitate bronchospasm. May induce attacks of asthma in susceptible subjects.

Warnings and adverse effects: Hypersensitivity to asthma. May induce gastro-intestinal haemorrhage, occasionally major.

Side-effects: Reports of side-effects are infrequent.

Overdosage: The conventional treatment of salicylate overdosage should be employed. Gastric lavage, forced alkaline diuresis and supportive therapy.

Pharmaceutical precautions Store at room temperature in a dry place and do not remove tablets from the foil until required.

Legal category P.

Package quantities Claradin Tablets are available in cartons of 100 tablets (10 strips of 10 tablets). The tablets are packed in moisture-proof aluminium foil.

Further information Claradin Tablets present aspirin in an effervescent form which dissolves completely in water giving a clear solution with a slight citrus flavour. Claradin has a sodium ion content of 7.1 mEq per tablet.

Product licence number 0188/0010.

CORTUCID* EYE DROP CREAM

Presentation Cortucid is a bland, fluid cream containing sulphacetamide sodium pH adjusted 10.0% w/w, hydrocortisone acetate 0.5% w/w in a water miscible cream base.

Uses Cortucid gives prompt relief of inflammatory conditions of the eye, whilst protecting the eye against the increased hazard of infection resulting from the use of a corticosteroid.

Cortucid is for the treatment of inflammatory eye conditions of either bacterial or allergic origin.

Dosage and administration It is suggested that the cream should be dropped into the eye every three to six hours until the condition improves (about two days). Thereafter the number of applications per day may be reduced, but treatment should be continued for at least two days after the condition has subsided.

Contra-indications, warnings, etc Cortucid should not be used in patients with ocular tuberculosis, herpes ophthalmicus, corneal ulceration, trachoma or glaucoma.

Cortucid is contra-indicated also in patients exhibiting true sensitivity to one of the ingredients.

Precautions: Topical administration of any corticosteroid to pregnant animals can cause abnormalities of foetal development. The relevance of this finding in human beings has not been established, however, topical steroids should not be used extensively in pregnancy i.e. in large amounts or for prolonged periods.

In infants, long term continuous topical therapy should be avoided. Adrenal suppression can occur even without occlusion.

Pharmaceutical precautions Store in a cool, dry place.

Legal category POM.

Package quantities Cortucid is packed in tubes containing 3 g.

Further information Inflammation of the eye, if allowed to persist, may result in the formation of vision-impairing scar tissue. Cortucid is formulated with hydrocortisone to safely suppress the inflammation and with sodium sulphacetamide, long considered to be the most suitable bacteriostat for local application in the eye.

Product licence number 0188/0010.

GENTICIN* CREAM GENTICIN* OINTMENT

Presentation Gentacin Cream is a white, smooth cream which contains gentamicin sulphate $\equiv$ 0.3% w/w gentamicin base (3,000 units per 1 g) in a water-miscible base.

Gentacin Ointment is a colourless, opaque ointment which contains gentamicin sulphate $\equiv$ 0.3% w/w gentamicin base (3,000 units per 1 g) in a greasy base.

Uses The unique broad spectrum of activity of Gentacin Cream and Ointment makes them ideally suitable for the topical treatment of all bacterial skin conditions.

Gentacin Cream and Ointment are indicated particularly in infected wounds, impetigo, varicose ulcers, Decubitus ulcers, Sycosis barbae, folliculitis, burns.

Dosage and administration Gentacin Cream and Ointment are intended for topical use only and should be

applied three to four times daily to the infected area, covering with a gauze dressing if necessary. Cream preparations are recommended for moist lesions and ointment for dry conditions.

Contra-indications, warnings, etc There are no specific contra-indications except in cases of true sensitivity to one of the ingredients.

Pharmaceutical precautions Store at room temperature. Do not freeze.

In order to preserve the therapeutic activity of these products they should not be diluted.

Legal category POM.

Package quantities Gentacin Cream and Ointment are available in 15 g and 100 g tubes.

Further information The unique range and degree of antibacterial activity of Gentacin coupled with freedom from troublesome side effects make it the antibiotic of choice for bacterial skin conditions, particularly where the pathogens involved or their sensitivity to antibiotics are unknown.

Product licence numbers

Gentacin Cream 0188/5926

Gentacin Ointment 0188/5927

GENTACIN* EYE/EAR DROPS

Presentation Gentamicin sulphate $\equiv$ 0.3% w/v gentamicin base in sterile aqueous isotonic solution. 10 ml opaque white polythene bottles with white plastic caps. Benzalkonium chloride and borax are included as preservatives.

Uses Gentacin (gentamicin) is a proven bactericidal antibiotic active against an extremely broad spectrum of Gram-positive and Gram-negative bacteria. Gentacin Eye/Ear Drops are therefore particularly useful in all external bacterial infections of the eye, where the bacterial organisms are often very varied.

In particular Gentacin Eye/Ear Drops are indicated in conjunctivitis, blepharitis, styes, corneal ulcers, prophylaxis in trauma.

Gentacin Eye/Ear Drops have also been used extensively in infected ear conditions.

Dosage and administration *For adults and children:*

Eyes: 1–3 drops instilled in affected eye three to four times a day or as required.

Ears: The area should be cleaned and 2–4 drops instilled three to four times a day and at night. In middle ear infections the cavity may be filled with drops.

Contra-indications, warnings, etc No special precautions are indicated.

Pharmaceutical precautions Store at room temperature. Do not freeze.

Legal category POM.

Package quantities Gentacin Eye/Ear Drops are available in opaque white polythene bottles with white plastic caps containing gentamicin sulphate $\equiv$ 0.3% w/v gentamicin base (3,000 units/ml).

Further information Gentisone HC Ear Drops are also available where a mild steroid (hydrocortisone acetate 1.0% w/v) is required in addition to Gentacin

(gentamicin sulphate 0.3% w/v) to treat infections complicated by an inflammatory condition such as often occurs in the outer ear.

Product licence number 0188/5007.

GENTACIN* EYE OINTMENT ▼

Presentation Gentacin Eye Ointment is a sterile, colourless, opaque ointment which contains gentamicin sulphate $\equiv$ 0.3% w/w gentamicin base (3,000 units per 1 g) in a greasy base.

Methylhydroxybenzoate and propylhydroxybenzoate are included as preservatives.

Uses Gentacin (gentamicin) is a proven bactericidal antibiotic active against an extremely broad spectrum of Gram-positive and Gram-negative bacteria. Gentacin Eye Ointment is therefore particularly useful in all external bacterial infections of the eye, where the bacterial organisms are often very varied.

In particular Gentacin Eye Ointment is indicated in conjunctivitis, blepharitis, styes, corneal ulcers, prophylaxis in trauma.

Dosage and administration *For adults and children:*

Gentacin Eye Ointment should be applied three to four times daily to the infected area.

Contra-indications, warnings, etc There are no specific contra-indications except in cases of true sensitivity to one of the ingredients.

Pharmaceutical precautions Store at room temperature. In order to preserve the therapeutic activity of Gentacin Eye Ointment it should not be diluted.

Legal category POM.

Package quantities Gentacin Eye Ointment is available in 3g tubes.

Further information The unique range and degree of antibacterial activity of Gentacin coupled with freedom from troublesome side effects make it the antibiotic of choice for bacterial eye conditions particularly where the pathogens involved or their sensitivity to antibiotics are unknown.

Product licence number 0188/0057.

GENTACIN* HC CREAM GENTACIN* HC OINTMENT

Presentation Gentacin HC cream is a white, smooth cream which contains hydrocortisone acetate 1.0% w/w, gentamicin sulphate $\equiv$ 0.3% w/w gentamicin base (3,000 units per 1 g) in a water-miscible base.

Gentacin HC Ointment is a colourless, opaque ointment which contains hydrocortisone acetate 1.0% w/w, gentamicin sulphate $\equiv$ 0.3% gentamicin base (3,000 units per 1 g) in a greasy base.

Uses Gentacin has been combined with 1.0% w/w hydrocortisone for the treatment of those inflammatory skin conditions where secondary bacterial infections may be involved.

Gentacin HC Cream and Ointment are indicated particularly in infective eczemas (infantile, atopic, allergic, seborrhoeic, etc), infective contact dermatitis, infected pemphigus, otitis externa, infected pruritus.

Dosage and administration Genticin HC Cream and Ointment are intended for topical use only and should be applied three to four times daily to the infected area, covering with a gauze dressing if necessary. Cream preparations are recommended for moist lesions and ointment for dry conditions.

Contra-indications, warnings, etc There are no specific contra-indications except in cases of true sensitivity to one of the ingredients.

Precautions: Topical administration of any corticosteroid to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established, however, topical steroids should not be used extensively in pregnancy i.e. in large amounts or for prolonged periods.

In infants long term continuous topical therapy should be avoided. Adrenal suppression can occur even without occlusion.

Steroids may delay the healing of leg ulcers or pressure sores.

Pharmaceutical precautions Store at room temperature. Do not freeze.

In order to preserve the therapeutic activity of these products they should not be diluted.

Legal category POM.

Package quantities Genticin HC Cream and Ointment are available in tubes of 15 g.

Further information The unique range and degree of antibacterial activity of Genticin coupled with freedom from troublesome side-effects make it the antibiotic of choice for bacterial skin conditions, particularly where the pathogens involved or their sensitivity to antibiotics are unknown.

Product licence numbers

Genticin HC Cream	0188/5922
Genticin HC Ointment	0188/5928

GENTICIN* INJECTABLE GENTICIN* PAEDIATRIC INJECTION

Presentation *Genticin Injectable:* Each 2 ml multidose vial and snap-off ampoule contains a 2 ml solution of gentamicin sulphate $\equiv$ 80 mg gentamicin base, with preservatives.

Genticin Paediatric Injection: Each 2 ml multidose vial contains a 2 ml solution of gentamicin sulphate $\equiv$ 20 mg gentamicin base, with preservatives.

Uses Genticin (gentamicin) is a proven bactericidal antibiotic active against an extremely broad spectrum of Gram-positive and Gram-negative pathogens including *Escherichia coli*, *Klebsiella*, *Proteus*, *Pseudomonas aeruginosa* and antibiotic-resistant strains of *Staph. aureus*. Genticin is often active against strains resistant to streptomycin, kanamycin and other unrelated antibiotics.

Indications for the use of Genticin are bacteraemia, septicaemia, urinary-tract infections, severe chest infections, severe neonatal infections and other systemic infections due to susceptible bacteria.

Dosage and administration Genticin is normally administered intramuscularly, but may be given intravenously if required.

If intravenous administration is necessary the normal intramuscular dose should be given as a bolus injection

into the tubing of the giving set or directly into the venous system over a period of two to three minutes. Genticin should not be given as a slow infusion or mixed with other drugs before use (see technical literature and below for incompatibilities).

With either intramuscular or intravenous administration the following dosage applies:

Adults: 60 kg and over: 80 mg eight-hourly.

Less than 60 kg: 60 mg eight-hourly.

Urinary-tract infections: As above.

Alternatively, if renal function is not impaired, 160 mg once daily may be used.

In life-threatening infections the frequency of dosage may need to be increased to six-hourly and the quantity of each dose may also be increased at the discretion of the clinician up to a total dosage of 5 mg/kg in 24 hours. In such cases it is advisable to monitor gentamicin serum levels.

Children: Genticin Paediatric Injection is one quarter the strength of Genticin Injectable (see above).

In children and in neonates, it can be expected that serum levels will be lower than those found in adults at equivalent dosage per body weight.

The recommended paediatric dosage is therefore as follows:

Up to 12 years: 6.0 mg/kg in 24 hours in 3 equally divided doses (i.e. 2.0 mg/kg eight-hourly).

In infants up to two weeks this dosage should be given in 2 equally divided doses (i.e. 3.0 mg/kg 12-hourly).

Serum levels should preferably be monitored daily.

In neonates, infants and children, subsequent dosage will often need to be increased to achieve therapeutic serum levels. Peak levels occur about one hour after intramuscular injection and should reach 4 mcg/ml, but not exceed 10 mcg/ml.

Contra-indications, warnings, etc There is no absolute contra-indication other than sensitivity to one of the ingredients.

Since those toxic symptoms that can be elicited are usually reversible, and since the conditions predisposing towards excess serum levels are well defined, it is considered that gentamicin is a relatively safe antibiotic for systemic therapy. As with all aminoglycosides, at critical levels gentamicin exhibits toxicity. With gentamicin the vestibular mechanism may be affected when serum levels of 10 μ g/ml are exceeded. This is usually reversible if observed promptly and the dose adjusted. In the patient with normal renal function it is virtually impossible to achieve these levels at standard dosage. Where renal function is impaired through disease or old age the frequency, but not the amount, of each dose should be reduced according to the degree of impairment. Gentamicin is excreted by simple glomerular filtration, and dosage frequency may be predicted by assessing creatinine clearance rates or blood urea and reducing the frequency accordingly. The following table may be useful when treating adults.

It is also advisable to check serum levels to confirm that peak (one hour) levels do not exceed 10 μ g/ml.

Genticin Injectable should not be used in pregnancy except in life-threatening situations.

Pharmaceutical precautions Genticin is a remarkably stable antibiotic and does not require to be kept under refrigerated conditions. In general we would not advise mixing Genticin Injectable with any other drug prior to administration.

<i>Blood urea (mg/100 ml)</i>	<i>Creatinine clearance (GFR) (ml/min)</i>	<i>Dose and frequency of administration</i>
< 40	> 70	80 mg† 8-hourly
40–100	30–70	80 mg† 12-hourly
100–200	10–30	80 mg† daily
> 200	5–10	80 mg† every 48 hours
Twice-weekly intermittent haemodialysis	< 5	80 mg† after dialysis

† 60 mg if body weight < 60 kg.

In particular the following are incompatible in mixed solution with Gentamicin Injectable: penicillins, cephalosporins, Erythromycin, Lipiphysan, heparins, †sodium bicarbonate.

Dilution in the body will obviate the danger of physical and chemical incompatibility and enable Gentamicin Injectable to be given concurrently with the drugs listed above either as a bolus injection into the drip tubing, with adequate flushing, or at separate sites. However, in the case of carbenicillin and gentamicin they should only be given at separate sites.

There is evidence that any potential nephrotoxicity of cephalosporins may be increased in the presence of gentamicin and we would recommend monitoring of kidney function if this combination is used. (For further information on mixed antibiotic therapy see section on 'Further information'.)

Neuromuscular blockade and respiratory paralysis have occasionally been reported from administration of aminoglycosides to patients who have received curare-type muscle relaxants during anaesthesia.

Legal category POM.

Package quantities *Gentamicin Injectable*: Ampoules and vials are packed in boxes of 5, 25 and 100 in trays of 5.

Gentamicin Paediatric Injection: Vials are packed in boxes of 5.

Further information Gentamicin has been shown to have a uniquely broad spectrum of activity and its use is recommended in bacterial infections where urgent, effective and, often, blind chemotherapy is called for. For combined antibiotic therapy with Gentamicin Injectable and Gentamicin Paediatric Injection the following rules of thumb may apply:

1. Gentamicin Injectable (or Gentamicin Paediatric Injection) act synergistically with penicillins and this combination is particularly useful against enterococci.

2. Gentamicin Injectable (or Gentamicin Paediatric Injection) and bacteriostatic antibiotics may give an antagonistic interaction (e.g. as with chloramphenicol). In the specific case of clindamycin and lincomycin the disadvantage of antagonism may be outweighed by the addition of activity against anaerobic organisms.

Product licence numbers

Gentamicin Injectable 0188/5909
Gentamicin Paediatric Injection 0188/5905

†Carbon dioxide may be liberated on addition of the two solutions. Normally this will dissolve in the solution, but under some circumstances small bubbles may form.

GENTICIN* INTRATHECAL

Presentation Gentamicin Intrathecal 2 ml snap-off ampoule. Each 1 ml contains Gentamicin Sulphate BP 1.0 mg gentamicin base (1,000 units) and Sodium Chloride Ph. Eur. (8.5 mg) to render the solution isotonic.

Uses Gentamicin (gentamicin) is a proven bactericidal antibiotic active against an extremely broad spectrum of Gram-positive and Gram-negative pathogens, including *E. coli*, *H. influenzae*, *Proteus*, *Pseudomonas*, *Neisseria meningitidis* and staphylococci which are the pathogens often associated with infection of the CSF.

Gentamicin Intrathecal is recommended for bacterial meningitis and ventriculitis.

Although gentamicin crosses the blood brain barrier it has been shown as with other antibiotics that parenteral therapy should be supported with intrathecal or intraventricular administration.

Dosage and administration The recommended daily dose is 1 mg gentamicin base intrathecally or intraventricularly plus 2.4 mg/kg/day intramuscularly in three equally divided doses at eight-hourly intervals in adult patients.

In children the supportive intramuscular dosage is: Up to 12 years: 6.0 mg/kg in 24 hours in three equally divided doses (i.e. 2.0 mg/kg eight hourly).

In infants up to two weeks this dosage should be given in two equally divided doses (i.e. 3.0 mg/kg 12 hourly).

The intraventricular/intrathecal dose may need to be increased at the discretion of the Clinician to obtain adequate CSF levels which can be controlled by assay, particularly if a severe degree of hydrocephalus is present. Treatment should continue until the CSF is shown to be bacteriologically clear.

Contra-indications, warnings, etc There are no absolute contra-indications.

Where renal function is impaired the frequency of dosage by *Systemic* routes should be reduced to avoid serum levels in excess of 10 mcg/ml.

In patients with normal renal function it is virtually impossible to achieve these levels with the standard dosage, but with gentamicin the vestibular mechanism may be affected when these levels are exceeded. This is usually reversible if observed in time and the dose adjusted.

Pharmaceutical precautions Gentamicin is a remarkably stable antibiotic and does not require to be kept under refrigerated conditions. In general we would not advise mixing Gentamicin Intrathecal with any other antibiotic prior to administration.

Legal category POM.

Package quantities Gentamicin Intrathecal is made available in boxes of 5.

Further information Shelf-life – four years.

Product licence number 0188/0004.

GENTICIN* PURE POWDER

Approved name: Gentamicin sulphate

Presentation Gentamicin Pure Powder is a non-sterile, hygroscopic powder. The weight of powder in each pack will vary according to potency, but will be approximately 1.8 g gentamicin sulphate to 1.0 g gentamicin base (1 million units).

Uses Genticin Pure Powder is supplied for the preparation of preservative-free solutions of gentamicin for intrathecal and intraventricular administration in meningitis and ventriculitis.

Dosage and administration The suggested daily dosage for all ages is 1 mg gentamicin base intraventricularly or intrathecally plus the recommended intramuscular dose of Genticin Injectable or Genticin Paediatric Injection. The intraventricular/intrathecally dose may need to be increased at the discretion of the clinician to obtain adequate CSF levels which can be controlled by assay, particularly if a severe degree of hydrocephalus is present.

Contra-indications, warnings, etc Where renal function is impaired the frequency of dosage by the systemic route should be reduced to avoid serum levels in excess of 10 mcg/ml. In the patient with normal renal function it is virtually impossible to achieve these levels with the standard dosage, but with gentamicin the vestibular mechanism may be affected when these levels are exceeded. This is usually reversible if observed in time and the dose adjusted.

Pharmaceutical precautions Genticin Pure Powder should be stored at room temperature and has a shelf-life of two years in *unopened* vials.

Care should be taken after the container has been opened to replace the stopper immediately.

Genticin Pure Powder may be dissolved in water or in normal saline for injection purposes in order to obtain a preservative-free solution. This should be sterilised before use, preferably by membrane filtration.

Legal category POM.

Package quantities Genticin Pure Powder is available in airtight, moisture-proof containers containing 1 g of gentamicin base.

Further information The package leaflet contained in every pack gives a suggested method for the preparation of intrathecal injection based on 1 mg of gentamicin base per 1 ml.

Product licence number 0188/5906.

GENTISONE* HC EAR DROPS

Presentation Gentamicin sulphate $\equiv$ 0.3% w/v gentamicin base plus 1.0% w/v hydrocortisone acetate as a sterile aqueous suspension in 10 ml opaque white polythene bottles with orange plastic caps. Borax and benzalkonium chloride are included as preservatives.

Uses Genticin (gentamicin) is a proven bactericidal antibiotic active against an extremely broad spectrum of Gram-positive and Gram-negative bacteria. Gentisone HC Ear Drops are therefore particularly useful in combating bacterial infections of the ear where the offending organisms are often varied and difficult to identify.

Gentisone HC Ear Drops are indicated in otitis externa, chronic suppurative otitis media, prophylaxis in trauma and pre- and post-operatively in surgery to the ear including infected mastoidectomy cavities.

Dosage and administration The area should be cleaned and 2–4 drops instilled three to four times a day and at night. In middle ear infections the cavity may be filled with drops.

Contra-indications, warnings, etc

There are no specific contra-indications except in cases of true sensitivity to one of the ingredients.

Precautions: Topical administration of any corticosteroid to pregnant animals can cause abnormalities of foetal development. The relevance of this finding in human beings has not been established, however, topical steroids should not be used extensively in pregnancy i.e. in large amounts or for prolonged periods.

In infants long term continuous topical therapy should be avoided. Adrenal suppression can occur even without occlusion.

Pharmaceutical precautions Store at room temperature. Do not freeze.

Legal category POM.

Package quantities Gentisone HC Ear Drops are available in 10 ml opaque white polythene bottles with orange plastic caps containing gentamicin sulphate $\equiv$ 0.3% w/v gentamicin base (3,000 units/ml) and 1.0% w/v hydrocortisone acetate.

Further information Genticin Eye/Ear Drops are also available where a plain antibiotic solution is required for topical application, for example, in the treatment of simple infections of the eye and ear.

Product licence number 0188/5925.

MICROPAQUE* D.C.

Presentation A low viscosity white suspension containing 100 % w/v of barium sulphate with a bland taste and particularly suited to the Double Contrast Technique.

Uses Radiological investigations of the gastro-intestinal tract.

Dosage and administration The volume of Micropaque D.C. used will depend on the patient, the procedure and technique involved. The following dosages represent a basic guide to the quantities suitable for routine examinations:

Barium Swallow.	40–60 ml undiluted
Double Contrast Stomach And Duodenum Examination	100–150 ml undiluted
Follow through Small Bowel Examination	150–250 ml undiluted
Barium Enema	250–500 ml diluted with 500–1000 ml water.

Contra-indications, warnings, etc Perforation of any region of the gastro-intestinal tract. Intestinal obstruction. Pyloric stenosis might be considered as contra-indications to the use of barium sulphate. Administration of a barium enema should proceed with particular care in patients with existing intestinal disease, in children, the elderly or the debilitated.

In choosing the route of administration, the possibility of actual or incipient bowel obstruction should be borne in mind.

Pharmaceutical precautions Shake well before use. Store at room temperature. Do not freeze. A light brown supernatant layer may appear and is quite normal. It will disappear when the bottle is shaken.

Legal category P.

Package quantities 300 ml plastic bottle containing 250 ml suspension and 50 ml 'shake space'. 15 bottles in each pack.

Further information Micropaque D.C., having a high density combined with a low viscosity, has been formulated to demonstrate particularly fine definition in conjunction with a suitable effervescent distending agent for Double Contrast Technique in the gastro-intestinal tract.

Product licence number 0838/0002.

MICROPAQUE* HD ▼

Presentation A fine white powder containing 96% w/w barium sulphate. It has a bland taste of vanilla.

Uses Double contrast radiological investigations of the gastrointestinal tract.

Dosage and administration Micropaque HD Powder must be reconstituted before use by adding water. 150 ml of a suspension containing 200% w/v barium sulphate is obtained by adding 83 ml water to 312 g of powder followed by vigorous shaking. Optimum dispersion is obtained by shaking for approximately one minute.

Although the volume of suspension used will depend on the patient, the procedure and technique involved, the following dosages of Micropaque HD represent a basic guide to the quantities suitable for routine examinations of the upper gastrointestinal tract.

Barium swallow	40–60 ml
Double contrast stomach and duodenum examination	100–150 ml
Follow-through examination of the small bowel	150–250 ml

Contra-indications, warnings, etc Perforation of any region of the gastrointestinal tract. Intestinal obstruction. Pyloric stenosis might be considered as a contra-indication to the use of barium sulphate. Administration of a barium enema should proceed with particular care in patients with existing intestinal disease, in children, the elderly or the debilitated.

Pharmaceutical precautions Store at room temperature in a dry place. Micropaque HD should be used as soon as possible after reconstitution and in any event within two hours of adding water.

Legal category P.

Package quantities 500 ml polypropylene beaker containing 312 g barium sulphate (96% w/w). 20 beakers in each pack.

Further information Micropaque HD produces a high density, low viscosity suspension on reconstitution that is especially designed for double contrast examinations of the upper gastrointestinal tract. It should be used in conjunction with a compatible gas producing agent such as Nicholas Co₂ Granules.

Product licence number 0188/0055.

MICROPAQUE* STANDARD

Presentation A creamy-white suspension containing 100% w/v of barium sulphate with a bland characteristic taste of butterscotch-vanilla.

Uses Radiological investigations of the gastro-intestinal tract.

Dosage and administration *Adults: Oesophagus:* Use undiluted Micropaque standard orally as required. For prolonged adhesion use Microtrast Oesophageal Paste.

Stomach and duodenum: To demonstrate the mucosal pattern use up to 50 ml of undiluted Micropaque standard orally, follow this with a further 100 ml of Micropaque standard diluted with 100 ml of water for demonstration of stomach distension and emptying function. If this biphasic technique is not used, 150 ml of Micropaque Standard diluted with 50 ml of water may be given.

Small intestine: Use 100 ml of Micropaque Standard diluted with 150 ml of water or follow through from stomach examination.

Colon: For examination by barium enema using the filled colon technique, use 1 volume of Micropaque standard to 2 volumes of water made up to the required quantity. For double contrast studies use 1–2 volumes of Micropaque standard to 1 volume of water. 400 ml total volume is usually sufficient. An important pre-requisite is a thorough cleansing preparation of the colon and an examination time of preferably not greater than 15 minutes.

Children: No children's dosage recommended as such investigations in children are rare and specialised. The dosage will therefore be tailored by the radiologist to suit the special requirements in each case.

Contra-indications, warnings, etc Perforation of any region of the gastro-intestinal tract. Intestinal obstruction. Paralytic ileus or pyloric stenosis might be considered as contra-indications to the use of barium sulphate preparations. Administration of a barium enema should proceed with particular care in patients with existing intestinal disease in children, the elderly or the debilitated. In choosing the route of administration, the possibility of actual or incipient bowel obstruction should be borne in mind.

Pharmaceutical precautions Shake before use.

Store at room temperature. Do not freeze. A light brown supernatant layer may appear and is quite normal. It will disappear when the bottle is shaken.

Legal category P.

Package quantities 250 ml plastic bottle, 2 litre plastic bottle.

Further information Nil.

Product licence number 0838/5903

MICROPAQUE* POWDER

Presentation A cream-coloured, free-flowing fine powder, which, when reconstituted with water, has a pleasant bland characteristic butterscotch/vanilla flavour. The powder contains 92% w/w barium sulphate.

Uses Radiological investigations of the gastro-intestinal tract.

Dosage and administration *Standard mix. Method of preparation:*

1. Measurement of volume. To 8 volumes of powder add 7 volumes of water, e.g. to 800 ml of powder add 700 ml of water to make 1 litre of liquid dispersion.

2. Measurement by weight. Add to 1 kg of powder sufficient water to make up to 1 litre of liquid dispersion. Water should always be added to the powder with slow stirring.

Adults: Oesophagus: Use undiluted Micropaque orally as required. For prolonged adhesion use Microtrast Oesophageal Paste.

Stomach and duodenum: To demonstrate the mucosal pattern use up to 50 ml of undiluted Micropaque orally. Follow this with a further 100 ml of Micropaque diluted with 100 ml of water for demonstration of stomach distension and emptying function. If this biphasic technique is not used, 150 ml of Micropaque Liquid diluted with 50 ml of water may be given.

Small intestine: Use 100 ml of Micropaque diluted with 150 ml of water or follow through from stomach examination.

Colon: For examination by barium enema using the filled colon technique use 1 volume of Micropaque to 2 volumes of water made up to the required quantity. For double contrast studies use 1–2 volumes of Micropaque to 1 volume of water. 400 ml total volume is usually sufficient. An important prerequisite is a thorough cleansing of the colon and an examination time of preferably not greater than 15 minutes.

Children: No children's dosage is recommended as such investigations in children are rare and specialised. The dosage will therefore be tailored by the radiologist to suit the special requirements in each case.

Contra-indications, warnings, etc Perforation of any region of the gastro-intestinal tract. Intestinal obstruction. Paralytic ileus or pyloric stenosis might be considered as contra-indications to the use of barium sulphate preparations. Administration of a barium enema should proceed with particular care in patients with existing intestinal disease, in children, the elderly or the debilitated. In choosing the route of administration, the possibility of actual or incipient bowel obstruction should be borne in mind.

Pharmaceutical precautions Store at room temperature in a dry place.

Legal category P.

Package quantities 3.5 kg plastic containers.

Further information Nil.

Product licence number 0838/5904.

MICROTRAST*

Presentation An off-white, viscous paste with a faint colour of vanilla and a bland, pleasant and characteristic faintly butterscotch/vanilla flavour. Contains 70% w/w barium sulphate.

Uses Radiographic study of the mucosal outline and pattern of the entire oesophagus, swallowing mechanism, oesophageal peristalsis, heart size and configuration.

Dosage and administration **Adults:** A large teaspoonful (10 g) to a tablespoonful (45 g) as required, orally.

Children: No children's dosage recommended as such investigations in children are rare and specialised. The dosage will therefore be tailored by the radiologist to suit the special requirements in each case.

Contra-indications, warnings, etc Perforation of any region of the gastro-intestinal tract. Paralytic ileus or pyloric stenosis might be considered as contra-indications to the use of barium sulphate preparations. Administration of a barium enema should proceed with particular care in patients with existing intestinal disease, in children, the elderly or the debilitated. In choosing the route of administration, the possibility of actual or incipient bowel obstruction should be borne in mind.

Pharmaceutical precautions Store at room temperature. Do not freeze.

Legal category P.

Package quantities 800 g in a plastic tube.

Further information Nil.

Product licence number 0838/5902.

NEO-MERCAZOLE* TABLETS

Presentation Round, shallow convex, pink, compression-coated tablet containing a white core. Impressed with 'B.S.' on one side and a bisecting line on the obverse. Each tablet contains Carbimazole BP 5 mg.

Uses Anti-thyroid agent. Neo-Mercazole is indicated in all conditions where reduction of thyroid synthesis is required.

1. Thyrotoxicosis (as the sole treatment).
2. Preparation prior to thyroidectomy (selected patients).
3. In combination with radioactive iodine ablative therapy.

Dosage and administration **Adults:** The usual initial total daily dose is 30 mg, but this may be increased to 40–60 mg daily in divided doses, in severe cases. Once control is achieved, dosage is gradually reduced to the lowest maintenance level, compatible with adequate control.

Children: The usual daily dosage is 15 mg or as directed by the physician.

Contra-indications, warnings, etc If reactions to neo-Mercazole are to be encountered, they normally occur within the first eight weeks of starting treatment. The most common minor side-effects are nausea, headache, arthralgia, mild gastric distress and skin rashes. Occasional hair loss has been reported. These side-effects are usually self-limiting and may not require withdrawal of the drug.

Bone-marrow depression has been reported, but these serious side-effects are rare and do not appear to be time or dose related. Routine blood tests are not necessary and, because of the nature of the disorder, are impractical, but it is imperative that patients be warned about the onset of sore throats or other manifestations which might suggest the early development of bone-marrow depression.

It is important that the drug is stopped and the physician concerned contacted immediately. There is some evidence that early withdrawal of the drug will lead to complete recovery.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Containers of 100 and 500 tablets.

Further information *Dosage and precautions in pregnancy:* The dose of Neo-Mercazole must be regulated by the patient's clinical condition. It is most important to appreciate that the basic metabolic rate is raised during pregnancy (the rise averages 25% above normal and occurs mainly in the second half of pregnancy) and that the dosage must be adjusted accordingly.

The smallest dose compatible with rendering the patient symptom-free should be employed and during the last three months should, if possible, not exceed 15 mg daily.

If the patient's condition is satisfactory, Neo-Mercazole should be discontinued three to four weeks before delivery. Neo-Mercazole is secreted in breast milk, and if treatment is continued during lactation, the patient should not be allowed to breast feed her baby.

Product licence number 0188/5907.

NEUTRADONNA* POWDER

Presentation White/off white powder. Each 1 g of powder contains aluminium sodium silicate 989.6 mg with belladonna alkaloids (calculated as hyoscyamine) 0.075 mg.

Uses Neutradonna is recommended for use in gastro-intestinal disorders, including peptic ulcer, hiatus hernia, pregnancy dyspepsia and other hyperacidic dyspepsias. Aluminium sodium silicate has a rapid but prolonged antacid action, and belladonna relaxes spasm of the gastro-intestinal tract and also reduces acid secretion by the stomach.

Dosage and administration *Adults:* 1 or 2 level 5 ml spoonfuls up to four times a day after meals. The powder should be taken stirred into a little milk or water. The last dose of Neutradonna each day should be taken at bedtime.

Children: 2-6 years: $\frac{1}{2}$ level 5 ml spoonful up to four times a day.

6-12 years: $\frac{1}{2}$ -1 level 5 ml spoonful up to four times a day.

Contra-indication, warnings, etc Glaucoma. Neutradonna should be prescribed with caution for patients having prostatic enlargement, or known sensitivity to Belladonna.

Side-effects: Dryness of the mouth and blurring of vision may occur on large doses due to the belladonna content of Neutradonna.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Containers of 25 g and 100 g powder.

Further information Nil.

Product licence number 0188/5908.

NEUTRADONNA* TABLETS

Presentation White circular bevelled tablets containing aluminium sodium silicate 650 mg, belladonna alkaloids (calculated as hyoscyamine) 0.048 mg.

Uses Neutradonna is recommended for use in gastro-intestinal disorders, including peptic ulcer, hiatus hernia,

pregnancy dyspepsia and other hyperacidic dyspepsias. Aluminium sodium silicate has a rapid but prolonged antacid action, and belladonna relaxes spasm of the gastro-intestinal tract and also reduces acid secretion by the stomach.

Dosage and administration *Adults:* 2-3 tablets up to four times a day. The tablets should preferably be chewed. The last dose of Neutradonna each day should be taken at bedtime.

Children: 2-6 years: $\frac{1}{2}$ -1 tablet up to four times a day.

6-12 years: 1-1 $\frac{1}{2}$ tablets up to four times a day.

Contra-indications, warnings, etc Glaucoma. Neutradonna should be prescribed with caution for patients having prostatic enlargement, or known sensitivity to Belladonna.

Side-effects: Dryness of the mouth and blurring of vision may occur on large doses due to the belladonna content of Neutradonna.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Box of 120 tablets (10 cartons of 12).

Further information Nil.

Product licence number 0188/5913.

PALAPRIN* FORTE TABLETS

Presentation Oval pale orange tablets. Embossed 'PALAPRIN FORTE' on one face and the reverse is scored and bears two oval symbols enclosing the letters 'BS'.

Each tablet contains aloxiprin 600 mg.

Uses Analgesic/anti-inflammatory agent in rheumatoid arthritis, osteoarthritis, various forms of spondylitis and other 'rheumatic' conditions where high dosage salicylate therapy is required.

Use in Pregnancy: There is clinical and epidemiological evidence of safety in human pregnancy.

Dosage and administration *Adults:* Usual dose 300-1200 mg.

Maximum 4.8 g daily in divided doses, i.e. one tablet per stone (6 kg) daily in divided doses. In acute rheumatic conditions up to 9.6 g daily in divided doses.

Dosage should be carefully controlled, and in conditions where high-dosage therapy is used, i.e. Still's disease, plasma salicylate levels should be monitored in accordance with the physician's requirements.

The tablets should preferably be dispersed in water before administration, but can be chewed, sucked or swallowed whole with a draught of water if required.

Contra-indications, warnings, etc

Contra-indications: True hypersensitivity to salicylates.

As with any form of salicylate, concurrent administration with anticoagulant therapy can lead to an alteration in prothrombin time which will necessitate a dosage adjustment based on laboratory studies. Active peptic ulceration; haemophilia.

Precautions: Aloxiprin may prolong labour and contribute to maternal and neonatal bleeding and is best avoided at term. May enhance effects of anti-coagulants. May inhibit action of uricosurics. May precipitate broncho-

spasm. May induce attacks of asthma in susceptible subjects.

Warnings and Adverse Effects: Hypersensitivity and asthma. May induce gastro-intestinal haemorrhage, occasionally major. May cause constipation and tinnitus.

Overdosage: The conventional treatment of salicylate overdosage should be employed – gastric lavage, forced alkaline diuresis and supportive therapy.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Containers of 250.

Further information The body-weight dosage regime has been recommended to ensure salicylate blood levels which will give anti-inflammatory, as well as analgesic, effect. Should this dosage produce tinnitus a downward adjustment of dose should be made until symptom disappears.

Aloxiaprin 600 mg is equivalent to acetylsalicylic acid 500 mg, but the salicylate is released largely in the alkaline medium of the small intestine, thereby reducing the likelihood of salicylate-induced dyspepsia.

Product licence number 0188/0038.

POLYCROL* GEL

Presentation A white peppermint-flavoured suspension containing in each 5 ml:

Activated methylpolysiloxane	25 mg
Magnesium hydroxide	100 mg
Aluminium hydroxide gel	4.75 ml

Uses Polycrol is recommended for use in gastro-intestinal disorders, including dyspepsia, peptic ulcer oesophagitis, hiatus hernia, post-operational abdominal pains. Polycrol rapidly relieves acid pain disperses gastric foam and assists eructation of gas and air.

The de-foaming action accelerates penetration of antacids throughout the gastric contents, thus protecting the gastric mucosa from the effects of excess acid.

Dosage and administration *Adults:* One or two 5 ml spoonfuls of gel three times a day after meals or as directed.

Children: 1–5 years: Half 5 ml spoonful three times a day.

6–12 years: One 5 ml spoonful three times a day. Or as directed.

Contra-indications, warnings, etc There are no known contra-indications to the use of Polycrol.

Side-effects: Nausea rarely encountered.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Bottles containing 300 ml of gel.

Further information Polycrol contains a balanced mixture of antacids (aluminium and magnesium hydroxides) together with a potent surface-active compound (methylpolysiloxane).

The antacids are balanced to avoid any bowel reaction and with Polycrol neither constipation nor diarrhoea will occur.

Product licence number 0188/5930.

POLYCROL* TABLETS

Presentation Circular, flat-faced tablet consisting of two layers, one green, the other white. Each tablet contains:

Activated methylpolysiloxane	25 mg
Aluminium hydroxide/magnesium carbonate co-dried gel	275 mg
Magnesium hydroxide	100 mg

Uses Polycrol is recommended for use in gastro-intestinal disorders, including dyspepsia, peptic ulcer, duodenitis, gastritis, flatulent dyspepsia, aerophagy, oesophagitis, hiatus hernia, post-operational abdominal pains. Polycrol rapidly relieves acid pain, disperses gastric foam and assists eructation of gas and air.

The de-foaming action accelerates penetration of antacids throughout the gastric contents, thus protecting the mucosa from the effects of excess acid.

Dosage and administration *Adults:* 1 or 2 tablets to be chewed two to three times a day after meals or as directed.

Children: 1–5 years: $\frac{1}{2}$ tablet to be chewed two to three times a day.

6–12 years: 1 tablet to be chewed two to three times a day.

Contra-indications, warnings, etc There are no known contra-indications to the use of Polycrol.

Side-effects: Nausea is rarely encountered.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Box of 200 tablets (10 cartons of 20 tablets).

Further information Polycrol contains a balanced mixture of antacids (aluminium and magnesium hydroxides) together with a potent surface-active compound (methylpolysiloxane).

The antacids are balanced to avoid any bowel reaction and with Polycrol neither constipation nor diarrhoea will occur.

Product licence number 0188/5919.

POLYCROL* FORTE GEL

Presentation A white, viscous, peppermint-flavoured gel. Each 5 ml contains:

Activated methylpolysiloxane	125 mg
Magnesium hydroxide	100 mg
Aluminium hydroxide gel	4.75 ml

Uses For antacid/deflatulent therapy in conditions such as: dyspepsia of functional or organic origin, heartburn, hiatus hernia, flatulence and abdominal distension, oesophagitis, gastritis, symptomatic treatment of peptic ulcer and other indications where flatulence/hyperacidity may be present.

Dosage and administration *Adults:* One to two 5 ml spoonfuls between meals and at bedtime or as directed.

Children: Under 5 years: Half 5 ml spoonful with food as required up to 6 doses per day.

5–12 years: One 5 ml spoonful as required up to 6 doses per day.

Contra-indications, warnings, etc

Contra-indications: There are no known contra-indications to the use of Polycrol.

Side-effects: Nausea is rarely encountered.

Pharmaceutical precautions Keep bottle well closed.

Legal category P.

Package quantities 300 ml plastic bottle.

Further information Nil.

Product licence number 0188/5929.

POLYCROL* FORTE TABLETS

Presentation White, circular, bi-convex tablets embossed 'N' on both faces. Each tablet contains:

Activated methylpolysiloxane	250 mg
Magnesium hydroxide	100 mg
Aluminium hydroxide/magnesium carbonate co-dried gel	275 mg

Uses For antacid/deflatulent therapy in conditions such as: dyspepsia of functional or organic origin, heartburn, hiatus hernia, flatulence and abdominal distension, oesophagitis, gastritis, symptomatic treatment of peptic ulcer and other indications where flatulence/hyperacidity may be present.

Dosage and administration One to two tablets between meals and at bedtime or as directed. The tablets should be chewed or sucked.

Not intended for administration to children.

Contra-indications, warnings, etc

Contra-indications: There are no known contra-indications to the use of Polycrol.

Side-effects: Nausea is rarely encountered.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities Containers of 100 tablets.

Further information Nil.

Product licence number 0188/5918.

VASCARDIN* TABLETS

Presentation White, bi-convex tablets, embossed with letter 'N' on one face and a break line on the other. Each tablet contains sorbide nitrate 10 mg.

Uses Angina pectoris – reduction of frequency and severity of attacks. Reduction of cardiac workload and oxygen consumption. Used alone or in combination with beta-blockade in certain patients.

Congestive cardiac failure, as adjunctive therapy.

Dosage and administration Oral: *for prophylaxis:* 1 tablet (10 mg) initially, 2–3 times daily rising as necessary up to 140 mg/day in divided doses.

Dosage should be increased gradually to minimise the possibility of nitrate headache and achieve tolerance. If the headache does occur, it can be relieved by simple analgesics.

Congestive cardiac failure: 10–30 mg 4 times daily as adjunctive therapy to other standard drugs (cardiac glycosides and diuretics).

Sub-lingual: 1 tablet, at the onset of acute anginal attacks, repeat if necessary.

Contra-indications, warnings, etc Use with caution in patients with glaucoma. If used concurrently with anticoagulant therapy, aspirin or other salicylates should not be taken. The product should not be used during pregnancy unless considered essential by the physician.

This product should not be used in patients with severe anaemia, head trauma or cerebral haemorrhage, nor in patients with known sensitivity to the nitrates.

Side-effects: During the first few days' treatment some patients may experience nitrate headache (see under 'Dosage and administration').

Pharmaceutical precautions Store in a dry place. Replace cap firmly after use.

Legal category P.

Package quantities Containers of 100 tablets.

Further information Nil.

Product licence number 0188/5931.

VELOSULIN*

Neutral Insulin Injection BP, highly purified pork.

Presentation Velosulin is a neutral solution that is available in 10 ml vials containing 40 iu/ml, 80 iu/ml and 100 iu/ml.

Uses Velosulin is for use in the treatment of insulin-dependent diabetics. It has a rapid onset and a short duration of action. It is particularly suitable in the treatment of diabetic coma and pre-coma. It may be mixed with Insulatard (NPH), Mixtard 30/70 or Inlitar 50/50 in all proportions without changing the characteristic effect of any of the types of insulin.

Velosulin has been manufactured from highly purified pork insulin.

The minimal antigenic properties of this insulin quality make it recommendable in the treatment of new insulin-demanding cases of diabetes, in the treatment of lipotrophy, insulin allergy and insulin resistance; also in the treatment of patients needing supportive insulin therapy, e.g. during pregnancy or operation.

Dosage and administration Velosulin may be given by subcutaneous, intramuscular or intravenous injection. The dosage is determined by the physician. Velosulin has a duration of action of some $\frac{1}{2}$ to 8 hours, having its maximum effect between 1 and 3 hours after injection.

Contra-indications, warnings, etc Insulin is contra-indicated in hypoglycaemia. In the event of an overdose, glucose should be given either orally or intravenously. Glucagon may also be administered.

Diabetics previously treated with insulin of beef or mixed beef/pork origin may require to have their dosage adjusted downwards if changed to Velosulin.

Pharmaceutical precautions Velosulin should be stored between 2 and 8 degrees centigrade, protected from sunlight. Insulin which has been frozen should not be used.

Legal category P.

Package quantities 10 ml vials of 40 iu/ml.
10 ml vials of 80 iu/ml.
10 ml vials of 100 iu/ml.

Further information Nil.

INSULATARD*

Isophane Insulin Injection (NPH) BP, highly purified pork.

Presentation Insulatard is a neutral suspension of highly purified microcrystalline pork insulin that is available in 10 ml vials containing 40 iu/ml, 80 iu/ml and 100 iu/ml.

Uses Insulatard is for use in the treatment of diabetics. It is given once or twice a day according to the needs of the patient. It may be mixed with Velosulin, Mixtard 30/70, or Inlitar 50/50 in all proportions without changing the characteristic effect of any of the types of insulin.

Insulatard has been manufactured from highly purified pork insulin.

The minimal antigenic properties of this insulin quality make it recommendable in the treatment of new insulin-demanding cases of diabetes, in the treatment of lipotrophy, insulin allergy and insulin resistance; also in the treatment of patients needing supportive insulin therapy, e.g. during pregnancy or operation.

Dosage and administration Insulatard may be given by subcutaneous or intramuscular injection. The dosage is determined by the physician. Insulatard has a duration of action of some $1\frac{1}{2}$ to 24 hours, having its maximum effect between 4 and 12 hours after injection.

Contra-indications, warnings, etc Insulin is contra-indicated in hypoglycaemia. In the event of an overdose, glucose should be given either orally or intravenously. Glucagon may also be administered.

Diabetics previously treated with insulin of beef or mixed beef/pork origin may require to have their dosage adjusted downwards if changed to Insulatard.

Pharmaceutical precautions Insulatard should be stored between 2 and 8 degrees centigrade, protected from sunlight. Insulin which has been frozen should not be used.

Legal category P.

Package quantities 10 ml vials of 40 iu/ml.
10 ml vials of 80 iu/ml.
10 ml vials of 100 iu/ml.

Further information Nil.

3132/0002 (80 iu/ml)
3132/0018 (100 iu/ml)

MIXTARD* 30/70 INITARD* 50/50

Presentation *Mixtard 30/70* is a neutral suspension of highly purified pork insulin comprising 30% Neutral Insulin Injection BP in solution and 70% Isophane Insulin Injection BP in microcrystalline form. Available in 10 ml vials containing 40 iu/ml (12 iu Neutral Insulin + 28 iu Isophane Insulin) 80 iu/ml (24 iu Neutral Insulin + 56 iu Isophane Insulin) and 100 iu/ml (30 iu Neutral Insulin + 70 iu Isophane Insulin).

Initard 50/50 is a neutral suspension of highly purified pork insulin comprising 50% Neutral Insulin Injection BP in solution and 50% Isophane Insulin Injection BP in microcrystalline form. Available in 10 ml vials containing 40 iu/ml (20 iu Neutral Insulin + 20 iu Isophane Insulin) 80 iu/ml (40 iu Neutral Insulin + 40 iu Isophane Insulin) and 100 iu/ml (50 iu Neutral Insulin + 50 iu Isophane Insulin).

Uses Treatment of insulin-dependent diabetics.

Mixtard 30/70 may be used once or twice daily, depending on the needs of the patient.

Initard 50/50 may be used once or twice daily, depending on the needs of the patient. It has a more intense initial effect than *Mixtard 30/70*.

Velosulin or *Insulatard* may be added to *Mixtard 30/70* or *Initard 50/50* in all proportions without changing the characteristic effect of any of the types of insulin.

The minimal antigenic properties of this insulin quality make it recommendable in the treatment of new insulin-demanding cases of diabetes, in the treatment of lipoatrophy, insulin allergy and insulin resistance. Also in the treatment of patients needing supportive insulin therapy, e.g. during pregnancy or operation.

Dosage and administration The dosage of *Mixtard 30/70* and *Initard 50/50* to be determined by the physician.

Mixtard 30/70 when injected subcutaneously has a duration of action of some $\frac{1}{2}$ to 24 hours, having its maximum effect between 4 and 8 hours. It may also be given by intramuscular injection, in which case the duration of action will be somewhat shorter.

Initard 50/50 when injected subcutaneously has a duration of action of some $\frac{1}{2}$ to 24 hours, having its maximum effect between 4 and 8 hours. It may also be given by intramuscular injection, in which case the duration of action will be somewhat shorter.

Initard 50/50 has a stronger initial effect than *Mixtard 30/70*.

Suspensions of *Mixtard 30/70* and *Initard 50/50* should be shaken gently before use.

Contra-indications, warnings, etc Insulin is contra-indicated in hypoglycaemia. In the event of overdosage, glucose should be given either orally or intravenously. Glucagon may also be administered. *Mixtard 30/70* or *Initard 50/50* suspensions should not be given intravenously.

Patients previously treated with other commercially available insulins of beef or mixed beef/pork origin may require to have their dosage reduced when transferred to *Mixtard 30/70* or *Initard 50/50*. The dosage reduction may be immediate, or occur over a period of weeks or months.

Pharmaceutical precautions *Mixtard 30/70* and *Initard 50/50* should be stored between 2 and 8 degrees centigrade, protected from sunlight. Insulin which has been frozen should not be used.

Legal category P.

Package quantities 10 ml vials of 40 iu/ml.
10 ml vials of 80 iu/ml.
10 ml vials of 100 iu/ml.

ALCOS-ANAL* OINTMENT

Presentation White ointment. Active ingredients:

Sodium oleate	10%
Hydroxypolyethoxydodecane	2%
Chlorothymol	0.1%

Uses Symptomatic relief of haemorrhoids and pruritus ani.

Dosage and administration Ease off cap of applicator and screw applicator on to tube. An applicator full of ointment should then be squeezed into the anal canal. Some ointment will remain in the applicator. To avoid wastage, the applicator should be left on the tube, wiped clean and the cap replaced.

External haemorrhoids should be massaged with the ointment in the usual way, night and morning and after every bowel action.

In addition, the usual precautions of strict cleanliness, avoidance of straining, and a bulky diet or a mild laxative to ensure soft stools, are essential.

Treatment should be carried out for at least six weeks, even though relief may be felt after only a few days. Treatment should be discontinued only when advised by the doctor.

Contra-indications, warnings, etc None reported. In a small number of cases the initial application may produce a burning sensation. The patient should persevere with the treatment as this feeling usually diminishes within two or three days.

Pharmaceutical precautions Store in a cool dry place.

Legal category P.

Package quantities Tube of 20 g packed in a carton with capped applicator.

Further information Nil.

Product licence number 0322/0032.

ALCOS-ANAL* SUPPOSITORIES

Presentation White, hard torpedo-shaped suppository. Active ingredients:

Sodium oleate	200 mg
Hydroxypolyethoxydodecane	20 mg
Chlorothymol	0.7 mg

Uses Symptomatic relief of haemorrhoids and pruritus ani.

Dosage and administration Rectal administration. Cleanse anal region after every bowel action. Insert one suppository every morning and night, also after every bowel action. Avoid straining during bowel action. Treatment should be carried out for at least six weeks, even though relief may be felt after only a few days.

Treatment should be discontinued only when advised by the doctor.

In addition, the usual precautions of strict cleanliness, avoidance of straining, and a bulky diet or a mild laxative to ensure soft stools, are essential.

Contra-indications, warnings, etc None reported. In a small number of cases the initial application may produce a burning sensation. The patient should persevere with the treatment as this feeling usually diminishes within two or three days.

Pharmaceutical precautions Store in a cool dry place.

Legal category P.

Package quantities Carton of 10 suppositories.

Further information Nil.

Product licence number 0322/0033.

CAMCOLIT*

Presentation *Camcolit 250*: White film coated tablets engraved on one side Camcolit, each containing 250 mg Lithium Carbonate BP (equivalent to 6.8 millimoles).

Camcolit 400: White film coated tablets, engraved one side Camcolit S with break line on reverse side, each containing 400 mg Lithium Carbonate BP (equivalent to 10.8 millimoles).

Uses Treatment and prophylaxis of mania, manic-depressive illness and recurrent depression.

Dosage and administration Tablets for oral administration.

Acute mania: Treatment of mania should be initiated in hospital where regular monitoring of serum lithium levels can be conducted.

The dosage of Camcolit should be adjusted to produce a serum lithium level between 0.6 and 1.2 mmol/l 12 hours after the last dose. The required serum lithium level may be achieved in one of two ways, but whichever is adopted regular estimations must be carried out to ensure maintenance of levels within the therapeutic range. For consistent results it is essential that the blood samples for serum lithium estimations are taken 12 hours after the last dose of lithium.

1. 1,500-2,000 mg of lithium carbonate are administered daily in divided doses for the first five or seven days. A blood sample for serum lithium estimation is taken 12 hours after the last dose on the fifth or seventh day, and the dosage of Camcolit is adjusted to keep the serum lithium level within the therapeutic range.

Subsequently, regular serum lithium estimations must be carried out and, where necessary, the dosage of Camcolit adjusted accordingly.

The precise initial dose of lithium should be decided in the light of the age and weight of the patient; young patients often require a dose higher than average and older patients a lower dose.

2. A lithium clearance test is carried out and the initial dosage calculated from the results. Even when the initial dosage is calculated in this way, it is still desirable that serum lithium levels should be determined at weekly intervals during the first three weeks of treatment, and any necessary adjustments to dosage made as a result of the levels actually obtained.

Most of the above applies in the treatment of hypomania as well as mania, but the patient (if not too ill) can be started on treatment as an outpatient provided that facilities for periodic serum lithium monitoring are available.

Prophylaxis of recurrent affective disorders (including unipolar mania, unipolar depressions and bipolar manic-depressive illness): A dosage of 500–1,200 mg of lithium carbonate can be administered daily in divided doses for the first seven days. A blood sample for serum lithium estimation is then taken 12 hours after the last dose, and the dosage of Camcolit is adjusted to keep the plasma lithium level within the effective range. Clinical improvement is usually associated with serum concentrations of 0.5 mmol/l or above. Toxic symptoms are usually associated with concentrations exceeding 1.5 mmol/l.

Use in elderly: Usually 500–1,000 mg/day given in divided doses.

Toxic symptoms are likely with serum concentrations above 1.0 mmol/l.

Use in children: Not recommended.

Measurement of serum lithium concentrations: Lithium therapy should not be initiated unless adequate facilities for routine monitoring of serum concentrations are available. On initiation of therapy serum concentrations should be measured weekly until stabilisation is achieved, then weekly for one month and at monthly intervals thereafter. Additional measurements should be made if signs of lithium toxicity occur (see below), on dosage alteration, development of significant intercurrent disease, signs of manic or depressive relapse and if significant change in sodium or fluid intake occurs.

As bioavailability varies from product to product a change of product should be regarded as initiation of new treatment. Blood levels should therefore be monitored weekly until re-stabilisation is achieved. More frequent monitoring is required if patients are receiving diuretics.

Contra-indications, warnings, etc The first consideration in lithium therapy is the selection of proper candidates. The second is the physical state of the patient, which must be adequate to handle the lithium ion when it is introduced into the body.

Contra-indications: Patients with renal disease, cardiovascular disease, Addison's disease or those breast feeding. There is epidemiological evidence that the drug may be harmful in human pregnancy. Should the use of lithium be unavoidable, close monitoring of serum concentrations should be made throughout the pregnancy and during parturition.

Precautions: Pre-treatment and periodic routine clinical monitoring is essential. This should include assessment of renal function, urine analysis, assessment of thyroid function and cardiac function, especially in patients with cardiovascular disease.

Patients should be euthyroid before the initiation of lithium therapy.

Clear instructions regarding the symptoms of impending toxicity should be given by the doctor to all patients receiving long-term lithium therapy (see Warnings and Adverse Effects). Patients should also be warned to report if polyuria or polydipsia develop. Episodes of nausea and vomiting or other conditions leading to salt/water depletion (including severe dieting) should also be reported. Patients should be advised to maintain their usual salt and fluid intake.

Elderly patients are particularly liable to lithium toxicity.

Lower doses of lithium may be needed during diuretic therapy as lithium clearance is reduced.

Raised plasma levels of ADH may occur during treatment.

Symptoms of nephrogenic diabetes are particularly prevalent in patients receiving concurrent treatment with tri/tetracyclic antidepressants.

Serum lithium concentrations may increase during concomitant therapy with indomethacin or tetracycline.

Warnings: Long-term treatment with lithium may result in permanent changes in the kidney and impairment of renal function. High serum concentrations of lithium, including episodes of acute lithium toxicity may enhance these changes. The minimum clinically effective dose of lithium should always be used. Patients should be maintained on lithium after 3–5 years only if, on assessment, benefit persists.

Renal function should be routinely monitored in patients with polyuria and polydipsia.

Side-effects: Side effects are usually related to serum lithium concentrations and are infrequent at levels below 1.0 mmol/l.

Mild gastro-intestinal effects, nausea, vertigo, muscle weakness and a dazed feeling may occur, but frequently disappear after stabilisation. Fine hand tremors, polyuria and mild thirst may persist. Some studies suggest that the tremor can be controlled by relatively small doses of propranolol.

Long term treatment with lithium is frequently associated with disturbances of thyroid function including goitre and hypothyroidism. These can be controlled by administration of small doses of thyroxine (0.05–0.2 mg daily) concomitantly with lithium. Thyrotoxicosis has also been reported.

Mild cognitive impairment may occur during long term use.

Hypercalcaemia, hypermagnesaemia, hyperparathyroidism and an increase in antinuclear antibodies have also been reported.

Exacerbation of psoriasis may occur.

Signs of impending toxicity: Appearance or aggravation of gastro-intestinal symptoms, muscle weakness, lack of co-ordination, drowsiness or lethargy may be early signs of intoxication. With increasing toxicity there is ataxia, giddiness, tinnitus, blurred vision, coarse tremor, muscle twitching and a large output of dilute urine. At blood levels above 2–3 mmol/l, there is increasing disorientation, seizures, coma and death.

Pharmaceutical precautions Store in a cool, dry place.

Legal category POM.

Package quantities Camcolit 250: 100 and 1,000 tablets.

Camcolit 400: 100 and 500 tablets.

Further information In view of recent reports of chronic nephrotoxicity attributed to lithium, it is important that for all lithium products the daily dose is divided and not given as a single dose. Such a procedure reduces the post-absorptive lithium peak and thus its concentration in the glomerular filtrate.

Product licence numbers Camcolit 250 0322/5900
Camcolit 400 0322/0015.

CYCLOBRAL*

Presentation Pink/brown hard gelatin capsules imprinted CYCLOBRAL. Each capsule contains 400 mg cycandelate.

Uses *Principal action:* Cyclobral is a vascular smooth muscle relaxant used to promote mild vasodilatation in peripheral and cerebrovascular diseases associated with impaired circulation.

Indications: Peripheral vascular disorders: Intermittent claudication, Raynaud's syndrome, night cramps, acrocyanosis, cold extremities, chilblains and 'restless legs'.

Cerebral vascular disorders: Chronic cerebral insufficiency, impaired mental function, dementia, confusion, dizziness and the sequelae of strokes.

Dosage and administration Cerebral and peripheral vascular disorders. Capsules for oral administration.

Adults: 1 capsule (400 mg) three or four times daily.

Children: Not recommended.

Contra-indications, warnings, etc

Contra-indications: Acute phase of cerebrovascular accidents or recent myocardial infarction. Actual or incipient peripheral gangrene or frostbite.

Special precautions: None.

Side-effects: Nausea, gastro-intestinal distress or flushing may occasionally occur.

Overdosage: Gastric lavage, followed, if necessary, by administration of vasopressors.

Pharmaceutical precautions Store in a cool dry place.

Legal category P.

Package quantities Capsules of 400 mg available in packs of 250.

Further information Cycandelate has a low order of toxicity and for maximum therapeutic effect it is recommended that four capsules daily should be given.

Product licence number 0322/0036.

ENZY PAN*

Presentation Chocolate-coloured, coated tablets containing: In the outer coat which dissolves in the stomach:

Pepsin BPC 1959 12 mg

In the inner core, which is specifically formulated to prevent solution in the stomach and to provide gradual release in the intestine:

Pancreatin BP 1968 180 mg

Desiccated ox bile 60 mg

Uses Replacement therapy in deficiencies of digestive enzymes. Loss of weight after surgery or in convalescence. Foetor-ex-ore.

Dosage and administration *Adults:* 2 or 3 tablets to be swallowed whole with water, during or after each meal.

No specific dosage recommendations can be made for children.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store in a cool dry place.

Legal category GSL.

Package quantities 120 tablets.

Further information In the total absence of pancreatic secretion, e.g. after pancreatectomy and in chronic pancreatitis, up to 6 tablets with each meal may be necessary for complete replacement.

Product licence number 0322/5002.

FYBRANTA*

Presentation Mottled, light brown tablets. Active ingredients.

Bran 2 g in a base containing calcium phosphate to neutralise the natural phytic acid content of the bran.

Uses The treatment of all colonic and other gastro-enterological diseases where administration of bran is indicated, including the treatment of constipation symptomatic relief in diverticular disease and the 'irritable colon' syndrome. Treatment of conditions requiring a high-fibre regimen.

The inclusion of calcium phosphate ensures neutralisation of the phytic acid in bran, which may otherwise interfere with calcium absorption.

Dosage and administration *Adults:* Usually 1-3 tablets three or four times daily preferably with meals.

At the discretion of the physician, larger quantities may be prescribed in individual cases.

Fybranta tablets should be chewed, part of a tablet at a time, and swallowed with a drink of liquid.

No attempt should be made to swallow the tablets whole.

Contra-indications, warnings, etc Intestinal obstruction, gluten enteropathies.

Pharmaceutical precautions Store in a cool dry place.

Legal category P.

Package quantities 100 tablets.

Further information Most of the published clinical evidence supporting the administration of fibre to patients suffering from pressure diseases of the colon has reported on the administration of bran, not on fibre of other vegetable origin.

Fybranta presents natural cereal fibre in a portable and palatable form.

Product licence number 0322/0016.

KAMILLOSAN* OINTMENT

Presentation Light brown ointment. Active ingredients:

Volatile oil of chamomile	0.5%
Hexyl Resorcinol BP	0.4%
Extract of chamomile	10%

Uses Prophylaxis and treatment of nappy chafe, nappy rash, sore and cracked nipples in nursing mothers, and chapped hands.

Dosage and administration Spread ointment evenly on lint and apply twice daily until the condition clears up. For prevention and treatment of nappy rash, it is advisable to apply the ointment whenever the nappies are changed.

Contra-indications, warnings, etc None known.

Pharmaceutical precautions Store in a cool dry place.

Legal category GSL.

Package quantities 20 g tube.

Further information Nil.

Product licence number 0322/5914.

MURIPSIN*

Presentation Orange, coated tablets. Active ingredients of one tablet:

Glutamic Acid Hydrochloride USNF X111	500 mg
Pepsin BPC 1959	35 mg

Uses The symptomatic treatment of gastric hydrochloric acid deficiency.

Dosage and administration *Adults:* 1 or 2 tablets with each meal.

No specific dosage recommendations can be made for children.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store in a cool dry place.

Legal category GSL.

Package quantities 50 tablets.

Further information Each Muripsin Tablet is approximately equivalent to the oral administration of 1 ml Dilute Hydrochloric Acid BP.

Product licence number 0322/5005.

NORGOTIN*

Presentation Colourless liquid. Active ingredients:

Ephedrine Hydrochloride BP	1%
Amethocaine Hydrochloride BP	1%
Chlorhexidine Acetate BP	0.1%
Propylene Glycol USP	to 100%

Uses Symptomatic relief of acute and subacute otitis media and otitis externa, used alone or as an adjunct to systemic chemotherapy.

Dosage and administration Twenty drops, or as much less as the ear will hold, instilled into the affected ear each hour until pain subsides, then every three hours.

Contra-indications, warnings, etc Should not be used in the presence of perforation of the tympanic membrane.

Pharmaceutical precautions Store in a cool dry place.

Legal category P.

Package quantities 16 ml dropper bottle.

Further information Nil.

Product licence number 0322/5008.

NORMACOL* ANTISPASMODIC

Presentation Orange, coated granules. Active ingredients:

Sterculia BP	62%
Alverine Citrate USNF X111	0.5%

Uses Treatment of spastic and hypertonic constipation. Treatment of the 'irritable colon' syndrome.

Dosage and administration *Adults:* 1–2 heaped 5 ml spoonfuls once or twice daily after meals.

Children: One half the above amount.

The granules should be placed dry on the tongue and, without chewing or crushing, swallowed with plenty of water.

When given to children, the granules may be administered conveniently by mixing with a little jam.

Contra-indications, warnings, etc Intestinal obstruction.

Pharmaceutical precautions Store in a cool dry place.

Legal category P.

Package quantities 500 g.

Further information Alverine citrate is a synthetic non-narcotic, non-habit-forming spasmolytic of a low order of toxicity in comparison with other anti-spasmodics. It is related to (but more than twice as active as) papaverine and has a specific effect on the smooth muscle of the gut, but not on those of the respiratory or cardiovascular system.

Product licence number 0322/5009.

NORMACOL* SPECIAL

Presentation White, coated granules. Active ingredient: Sterculia BP 62%.

Uses Treatment of constipation during pregnancy and lactation. Management of colostomies and ileostomies. 'High residue diet' management of diverticular disease of the colon. Administration after ingestion of sharp foreign bodies to provide a coating thus reducing the possibility of intestinal damage during transit.

Dosage and administration (other than in the management of ileostomy and colostomy). *Adults:* 1–2 heaped 5 ml spoonfuls once or twice daily after meals.

Children: One half the above amount.

The granules should be placed dry on the tongue and, without chewing or crushing, swallowed with plenty of water.

When given to children, the granules may be administered conveniently by mixing them with a little jam.

Contra-indications, warnings, etc Intestinal obstruction.

Pharmaceutical precautions Store in a cool dry place.

Legal category GSL.

Package quantities 500 g.

Further information Sterculia is a vegetable gum which absorbs up to 60 times its own volume of water, i.e. six times as much as methylcellulose or psyllium.

Product licence number 0322/5010.

NORMACOL* STANDARD

Presentation Brown, coated granules. Active ingredients:

Sterculia BP	62%
Frangula BPC 1949	8%

Uses Treatment of habitual constipation. The initiation and maintenance of bowel action after rectal surgery and after haemorrhoidectomy.

Dosage and administration *Adults:* 1–2 heaped 5 ml spoonfuls once or twice daily after meals.

Children: One half the above amount.

The granules should be placed dry on the tongue and, without chewing or crushing, swallowed with plenty of water.

When given to children, the granules may be administered conveniently by mixing them with a little jam.

Contra-indications, warnings, etc Intestinal obstruction.

Pharmaceutical precautions Store in a cool dry place.

Legal category GSL.

Package quantities 200 g and 500 g.

Further information Sterculia is a vegetable gum which absorbs up to 60 times its own volume of water, i.e. six times as much as methylcellulose or psyllium.

Product licence number 0322/5011.

NORMACOL* STANDARD SUGAR FREE FORMULA

Presentation Brown, sugarless, coated granules. Active ingredients:

Sterculia BP	62%
Frangula BPC 1949	8%

Uses Treatment of habitual constipation. The initiation and maintenance of bowel action after rectal surgery and after haemorrhoidectomy.

Dosage and administration *Adults:* 1–2 heaped 5 ml spoonfuls once or twice daily after meals.

Children: One half the above amount.

The granules should be placed dry on the tongue and, without chewing or crushing, swallowed with plenty of water.

Contra-indications, warnings, etc Intestinal obstruction.

Pharmaceutical precautions Store in a cool dry place.

Legal category GSL.

Package quantities 500 g.

Further information Use as Normacol Standard where carbohydrate intake must be restricted.

Product licence number 0322/5017.

NORMACOL-X*

Presentation White, coated granules accompanied by orange, uncoated tablets.

The active constituent of the granules is Sterculia BP 62%.

The active ingredient of each tablet is Danthron BP 200 mg.

Uses The preparation of patients for abdominal radiography.

Dosage and administration *Adults:* 2 heaped 5 ml spoonfuls of the granules after breakfast, and 1 tablet on retiring. This routine is maintained over the two days preceding that of the examination.

The granules should be placed dry on the tongue and, without chewing or crushing, swallowed with plenty of water.

Children: Not recommended.

Contra-indications, warnings, etc Intestinal obstruction.

In common with all contact laxatives Danthron may cause slight transient discomfort in a small percentage of patients. As the granules provide adequate bulk in the colon, such discomfort usually disappears with the resulting defaecation. Danthron may cause temporary harmless pink or red colouring of the urine.

Pharmaceutical precautions Store in a cool dry place.

Legal category P.

Package quantities Outers of 50 postal packs each containing 40 g granules and 2 tablets.

Further information Each pack contains sufficient granules to enable one further dose to be taken after examination to overcome the tendency to constipation due to dehydration or residual unevacuated barium.

Product licence number 0322/0014.

POSALFILIN*

Presentation Dark brown ointment (fatty base). Active ingredients:

Podophyllum Resin BP	20%
Salicylic Acid BP	25%

Uses Treatment of plantar warts.

Dosage and administration

1. Place a felt corn ring (not a corn plaster) around the wart, if necessary adjusting the size of the hole by snipping, allowing the wart to protrude through the hole.

2. Apply the ointment (using a minimum amount) to exposed wart only. Cover with a piece of plaster.

3. The dressing may be renewed two or three times weekly. When wart appears soft and spongy leave exposed to the air for a day or two when it will usually drop off. If not, repeat the above procedure.

4. Wash hands thoroughly after applying the ointment, and if a waterproof plaster is used normal washing will not effect the efficacy of the treatment.

The treatment can be applied by the patient at home, there are instructions in every pack.

Contra-indications, warnings, etc Posalfilin should only be used under medical supervision.

The patient should be warned that Posalfilin Ointment is extremely caustic to healthy skin.

It should be stressed that if any pain or inflammation is experienced during treatment with Posalfilin, application should be discontinued until the inflammation has subsided.

Pharmaceutical precautions Store in a cool dry place.

Legal category P.

Package quantities 10 g tube.

Further information Nil.

Product licence number 0322/5901.

PREFIL*

Presentation Brown, coated granules. Active ingredient: Sterculia BP 55%.

Uses *Principal action:* The active constituent of Prefil swells in the stomach, by absorption of water, to produce a feeling of satiety. Taken before meals as part of a planned dietary programme, Prefil facilitates appetite control.

Indications: Obesity.

Dosage and administration *Adults:* Two rounded 5 ml spoonfuls, $\frac{1}{2}$ to 1 hour before each meal. The granules should be placed dry on the tongue, in small quantities if necessary, and without chewing or crushing, swallowed with a tumblerful ($\frac{1}{2}$ pint) of water.

Children: At the discretion of the physician, when a reduced dosage may be given.

Contra-indications, warnings, etc

Contra-indications: Intestinal obstruction.

Precautions: Some patients who have become accustomed to an unusually low residue diet may experience slight abdominal discomfort from the increase in bulk which follows the administration of full doses of Prefil. These patients may be advised to take a smaller dose initially, increasing to the full dose over a period of one week. In these circumstances, the full clinical effect may not be experienced until the end of the first week.

Pharmaceutical precautions Store in a cool dry place.

Legal category GSL.

Package quantities 500 g.

Further information The active ingredient of Prefil is totally unabsorbed and therefore appetite control is

facilitated without inducing the systemic problems often associated with other anti-obesity preparations.

Available carbohydrate content approx. 1.6 g per spoonful (as sucrose) equivalent to 6 Cals.

Product licence number 0322/0035.

PYRALVEX*

Presentation Brown liquid. Active ingredients:

Extract of Anthraquinone glycosides	5%
Salicylic Acid BP	1%

Uses Treatment of inflammatory conditions of the oral mucosa.

Dosage and administration To be applied to the inflamed oral mucosa (after removing any dentures worn) three or four times daily using the brush provided.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store in a cool place.

Legal category P.

Package quantities 10 ml bottle with brush.

Further information A double-blind study indicated that in topical treatment of inflammatory diseases of the oral and oropharyngeal mucosa, Pyralvex was more effective than corticosteroids.

Product licence number 0322/5013.

SOMNITE*

Presentation Round, white, uncoated, flat, bevel-edged tablets of 12 mm diameter with a single break line on one side and sailing boat design on the other. Each tablet contains Nitrazepam BP 5 mg.

Uses *Principal action:* Somnite is a non-barbiturate hypnotic agent which rapidly induces sleep lasting six to eight hours, by inhibiting stimuli to brain centres which maintain wakefulness.

Indications: Short term treatment of insomnia where daytime sedation is acceptable.

Dosage and administration *Adults:* 5 mg (1 tablet) before retiring. This average dose may, if necessary be increased up to 10 mg and for in-patients up to 20 mg.

Elderly patients: 2.5–5 mg.

Children: Not recommended.

Contra-indications, warnings, etc

Contra-indications: Known sensitivity to benzodiazepines. Acute pulmonary insufficiency.

There is no evidence as to drug safety in human pregnancy nor is there evidence from animal work that it is free from hazard. Do not use during pregnancy, especially during the first and last trimesters, unless there are compelling reasons.

Precautions: Chronic pulmonary insufficiency. In chronic renal or hepatic disease. In labour. High single doses or repeated low doses have been reported to produce hypotonia, poor sucking and hypothermia in the neonate and irregularities in the foetal heart. Avoid if possible in lactation. The concurrent use of other CNS depressant drugs should be avoided.

Warnings and side-effects: Common adverse effects include drowsiness, sedation, blurring of vision, un-

steadiness and ataxia. These effects occur following single as well as repeated dosage and may persist well into the following day. Performance at skilled tasks and alertness may be impaired. Patients should be warned of this hazard and advised not to drive or operate machinery during treatment. These effects are potentiated by alcohol. The elderly are particularly liable to experience these symptoms together with confusion especially if organic brain symptoms are present. See also Dependence Potential and Withdrawal Symptoms below.

Abnormal psychological reactions to benzodiazepines have been reported. Rare behavioural adverse effects include paradoxical aggressive outbursts, excitement, confusion, and the uncovering of depression with suicidal tendencies.

Other rare adverse effects including hypotension, gastro-intestinal and visual disturbances, skin rashes, urinary retention, headache, vertigo, changes in libido; blood dyscrasias and jaundice have also been reported.

Dependence potential and withdrawal symptoms: In general the dependence potential of benzodiazepines is low but this increases when high dosages are attained, especially when given over long periods. This is particularly so in patients with a history of alcoholism, drug abuse or in patients with marked personality disorders. Regular monitoring of treatment in such patients is essential and routine repeat prescriptions should be avoided.

Treatment in all patients should be withdrawn gradually as symptoms such as depression, nervousness, rebound insomnia, irritability, sweating and diarrhoea have been reported following abrupt cessation of treatment in patients receiving even normal therapeutic doses for short periods of time.

Abrupt withdrawal following excessive dosage may produce confusion, toxic psychosis, convulsions or a condition resembling delirium tremens.

Overdosage: The primary symptoms of overdosage are drowsiness, dizziness, ataxia and slurred speech. Treatment is symptomatic but gastric lavage may be useful if performed soon after ingestion.

Pharmaceutical precautions Somnite tablets should be stored in a cool, dry place and protected from light and moisture.

Legal category POM.

Package quantities Somnite tablets 5 mg are available in packs of 100 and 500.

Further information Somnite is a long acting benzodiazepine. Repeated dosage will lead to accumulation of whole drug and metabolites. The elderly and patients with impaired renal and/or hepatic function will be particularly susceptible to the adverse effects listed above. Treatment should be kept to a minimum and given only under close medical supervision.

Little is known regarding efficacy or safety of benzodiazepines in long-term use. It is advisable to review treatment regularly and to discontinue use as soon as possible.

Somnite does not induce microsomal enzymes as may occur with barbiturates and may be given together with commonly used cardiovascular drugs, anticoagulants, antihypertensives, stimulants, spasmolytics, antidepressants and chemotherapeutic agents.

Product licence number 0322/0034.

SPASMONAL*

Presentation Blue/grey opaque hard gelatin capsules, each containing 60 mg Alverine Citrate USNF XIII.

Uses Selective smooth muscle spasmolytic.

Dosage and administration *Adults:* 1 or 2 capsules one to three times daily, orally.

No specific dosage recommendations can be made for children.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store in a cool dry place.

Legal category P.

Package quantities 100 capsules.

Further information Alverine citrate is a synthetic, non-narcotic, non-habit-forming spasmolytic of a low order of toxicity in comparison with other anti-spasmodics. It is related to (but more than twice as active as) papaverine, and has a specific effect on the smooth muscle of the intestine and uterus, but not on those of the respiratory or cardiovascular system.

Product licence number 0322/5014.

TAMPOVAGAN* 'N' (NEOMYCIN) PESSARIES

Presentation Off-white, hard vaginal pessaries. Active ingredient: Neomycin Sulphate BP 20 mg.

Uses Treatment of intractable vaginitis.

Dosage and administration Two pessaries to be inserted high into the vagina every night before retiring to bed. Treatment should be continued throughout the period of menstruation.

Contra-indications, warnings, etc None reported. Neomycin sulphate in the form of pessaries rarely causes irritation or allergic reaction, but should clearly not be used in patients with a known sensitivity to neomycin. Not recommended for children.

Pharmaceutical precautions Store in a cool dry place.

Legal category POM.

Package quantities Cartons of 10.

Further information Nil.

Product licence number 0322/5909.

TAMPOVAGAN* STILBOESTROL AND LACTIC ACID PESSARIES

Presentation Off-white, hard, vaginal pessary. Active ingredients:

Stilboestrol BP 0.5 mg in a base containing Lactic Acid BP 5%.

Uses Treatment of atrophic vaginitis, senile vaginitis and menopausal vaginitis.

Dosage and administration Two pessaries to be inserted high into the vagina at night.

Contra-indications, warnings, etc Should not be used in pregnancy or suspected pregnancy or in women who might become pregnant. Not recommended for children.

Pharmaceutical precautions Store in a cool dry place.

Legal category POM.

Package quantities Cartons of 10.

Further information Nil.

Product licence number 0322/5910.

WAXSOL*

Presentation Colourless liquid. Active ingredient: Docusate sodium 5% in a water-miscible base.

Uses Cerumenolytic.

Dosage and administration For aural use only. The patient should be directed to fill the ear with Waxsol on two consecutive nights only, before attending for syringing.

Contra-indications, warnings, etc Should not be used in the presence of perforation of the ear drum or when there is inflammation of the ear. Discontinue use if any pain or inflammation is experienced.

Pharmaceutical precautions Store in a cool place.

Legal category GSL.

Package quantities 16 ml dropper bottle.

Further information Waxsol, because of its low surface tension and its water-miscibility, rapidly penetrates the dry matrix of the ceruminous mass, reducing the solid material to a semi-solid debris which can be syringed away readily or, in less severe and in chronic cases, is ejected by normal physiological processes.

Product licence number 0322/5016.

**Trade Mark*

Norwich-Eaton Limited
Regent House
The Broadway, Woking
Surrey GU21 5AP

ALPHADERM*

Presentation Alphaderm is a translucent white cream containing hydrocortisone 1% and hypermolar urea 10% in a specially formulated powder-in-cream base which assists the percutaneous transportation of the active ingredients to the site of action. Alphaderm does *not* contain lanolin or parabens. The base is self-occlusive and ambiphilic and may be used either as a cream or an ointment.

Uses Alphaderm is indicated for the treatment of: eczema, including atopic, infantile and hyperkeratotic; intertrigo; neurodermatitis and all lichenoid conditions; contact dermatitis; photosensitivity reactions and prurigo.

Dosage and administration Alphaderm is applied topically. Wash affected areas well, dry, and apply directly to the lesions twice daily. Because it has a pH bordering on that of the skin, Alphaderm may be rubbed in well without causing irritation or stinging, even when applied to abrasions or to areas of broken skin. Occlusive dressings may be used but are usually unnecessary because of the self-occlusive nature of the special base.

Contra-indications, warnings, etc Alphaderm is contra-indicated in bacterial, viral and fungal diseases of the skin.

Precautions: In pregnant animals, administration of corticosteroids can cause abnormalities of foetal development. The relevance of this finding in human beings has not been established. However, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for long periods. In infants, long-term continuous topical therapy should be avoided. Adrenal suppression can occur even without occlusion.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities Alphaderm is available in tubes of 30 g and 100 g.

Further information Though the preparation has a non-greasy texture, the hydrocortisone content is micronised and dispersed in an oily medium. This is probably responsible for the long-lasting therapeutic effect which has been noted after the application of Alphaderm. Optimum rehydration of dry skin is achieved without the use of occlusive dressings.

Product licence number 0364/0019.

AQUADRATE*

Presentation Aquadrate is a translucent white cream containing hypermolar urea 10% in a specially formulated powder-in-cream base. Because of its keratolytic action it hydrates and penetrates the epidermis. Although Aquadrate has a non-greasy texture, the polysaccharide

matrix on to which the urea is adsorbed is dispersed in an ambiphilic medium which imparts a self-occlusive property. It therefore fulfils the functions of both an ointment and a cream. Aquadrate does *not* contain lanolin, parabens or any preservative likely to irritate or sensitise the skin.

Uses Aquadrate is indicated in ichthyosis, xeroderma, hyperkeratosis and other chronic dry skin conditions. It is also useful in the treatment of steroid-induced rosacea.

Dosage and administration Aquadrate is applied topically. Wash affected areas well, rinse off all traces of soap, dry, and apply sparingly. Use as often as necessary. Because it has a pH bordering on that of the skin, Aquadrate may be rubbed in well without causing stinging, even when applied to abrasions and areas of broken skin. Occlusive dressings may be used but are usually unnecessary because of the self-occlusive nature of the cream.

Contra-indications, warnings, etc There are no contra-indications to the use of Aquadrate.

Pharmaceutical precautions There are no special storage requirements.

Legal category P.

Package quantities Aquadrate is available in tubes of 30 g and 100 g.

Further information Nil.

Product licence number 0364/0018.

CHLORASEPTIC LIQUID

Presentation Chloraseptic liquid consists of a dark green, aqueous solution containing phenol BP and sodium phenolate (total phenol 1.4%), menthol, thymol and glycerin.

Uses Chloraseptic liquid is recommended for the relief of the pain associated with sore throat (pharyngitis), tonsillitis and superficial mucosal lesions as well as aphthous ulcers, Vincent's ulcers, moniliasis, and denture ulcers. Chloraseptic will also relieve post-operative pain following dental surgery. Chloraseptic will also control halitosis associated with minor mouth and throat infections.

Dosage and administration *Spray:* For sore throat – use full strength – Adults should spray throat five times at first; children from 6–12 years, three times. Repeat every two hours if necessary.

Gargle: As a gargle for sore throat – use full strength or dilute with equal parts of water. Rinse thoroughly, then expel remainder.

Mouthwash: For mouth and gum irritations – use full

strength. Rinse for 15 seconds, then expel remainder. As a deodorising mouthwash – use full strength or dilute with equal parts of water. Rinse thoroughly, then expel remainder.

Contra-indications, warnings, etc Not to be given to children under six years unless directed by physician. Consult physician if sore throat is severe or lasts more than two days, or is accompanied by high fever, headache, nausea or vomiting.

Pharmaceutical precautions Nil.

Legal category P.

Package quantities 120 ml with spray attachment and 150 ml bottle.

Further information Nil.

Product licence number 0364/0023.

DANTRIUM*

Presentation Dantrium capsules are available in two strengths, containing either 25 mg or 100 mg dantrolene sodium per capsule.

Dantrium is presented in orange/cream capsules. The 25 mg capsule carries the monogram Eaton 030 on both sections of the capsule. The 100 mg capsule carries the monogram Eaton 033 on both sections.

Uses Dantrium produces relaxation of contracted skeletal muscle by affecting the contractile response at a site beyond the myoneural junction. Dantrium produces a dissociation of excitation-contraction coupling, probably by interfering with the release of Ca^{++} from the sarcoplasmic reticulum. The effect is seen in both fast and slow fibres but is more pronounced in the former.

Dantrium is indicated for the treatment of chronic, severe spasticity resulting from such disorders as stroke, multiple sclerosis, spinal cord injury and cerebral palsy. It is useful in these conditions whenever spasticity is so severe that increased muscular resistance to stretch, clonus or exaggerated reflex posturing interfere with the activities of daily living such as exercise, posture, equilibrium, walking, transfer manoeuvres or the use of braces.

Occasionally, only a subtle but perceptible improvement in spasticity may occur with Dantrium therapy. In such instances information regarding improvement should be sought from the patient and those who are in constant daily contact and attendance on him. Brief withdrawal of Dantrium for a period of two to four days will frequently demonstrate exacerbation of the spasticity and may help to reinforce a previously indefinable clinical impression.

Dosage and administration Before commencing Dantrium therapy, it is important to set an attainable therapeutic goal for the individual patient. Such a goal would be a reduction in spasticity which allows the patient or his attendants to carry out a function which could not previously be performed or one that he or his attendants consider important.

The need for patience and attention to the individual patient's needs in titrating Dantrium dosage is of paramount importance.

Dosage should be increased until the maximum benefit compatible with the patient's neurological deficit is achieved.

The lowest dose compatible with optimal response is

recommended, dosage in excess of 400 mg/day is not recommended.

A recommended dosage increment scale is shown below:

Week	Recommended dosage
First	One 25 mg capsule daily
Second	One 25 mg capsule twice daily
Third	Two 25 mg capsules twice daily
Fourth	Two 25 mg capsules three times daily
Fifth	Three 25 mg capsules three times daily
Sixth	Three 25 mg capsules four times daily
Seventh	One 100 mg capsule four times daily

Most patients will achieve their therapeutic goal at a titrated dose of 75 mg three times daily.

If no observable benefit is derived from the administration of Dantrium after a total of 45 days, therapy should be discontinued.

Many patients experience side effects such as weakness and fatigue during the first four weeks of therapy whilst the patient adjusts to the changes in muscle tone induced by the drug. They are usually transient and mild in nature. Patients should be warned of them and encouraged to persevere with treatment. Should it be necessary the dosage of Dantrium may be reduced and then gradually increased according to the patient's tolerance. It may be possible to reduce the duration of each dosage stage to four days, depending on the patient's reaction to the drug.

Contra-indications, warnings, etc

Contra-indications. Dantrium is contra-indicated where spasticity is utilised to sustain upright posture and balance in locomotion or whenever spasticity is utilised to obtain or maintain increased function.

Dantrium is contra-indicated in patients with evidence of hepatic dysfunction. Isolated cases of jaundice in patients receiving Dantrium have been reported.

Dantrium should not be administered to children.

Warnings: *Usage in pregnancy:* Although teratological studies in animals have proved satisfactory, as with all new medicines the safety of Dantrium in pregnancy has not been established. In such patients, the potential benefits must be weighed against the possible hazards.

Precautions: Dantrium has a potentially hepatotoxic action. Before beginning Dantrium therapy, liver function tests should be performed in all patients (SGOT or SGPT, alkaline phosphatase, total bilirubin, LDH, or their equivalents) to establish a base-line, and to rule out pre-existing liver disease. These tests should be repeated upon hospital discharge or at six weeks after starting therapy; further tests may be carried out at the physician's discretion. Generally, if these studies reveal abnormal values, therapy should not be commenced or should be discontinued when other causes for these abnormalities cannot be found. Some patients have reverted to normal laboratory values during continuation of therapy, whilst others have not.

The use of Dantrium with other potentially hepatotoxic drugs should be avoided.

Dantrium should be used with caution in patients with impaired pulmonary function, particularly those with obstructive pulmonary disease, and in patients with severely impaired cardiac function due to myocardial disease.

Patients should be advised not to drive a motor vehicle

or to undertake potentially dangerous work until Dantrium therapy has been stabilised.

Although the primary pharmacological effect of Dantrium is exerted directly on skeletal muscle, caution should be exercised in the concomitant administration of tranquillising agents.

Action in event of overdose: For acute overdose, general supportive measures should be employed along with immediate gastric lavage.

Fluids should be administered in large quantities to avert the theoretical possibility of crystalluria.

Side-effects and adverse reactions: The most frequently occurring side-effects of Dantrium have been drowsiness, dizziness, weakness, general malaise, fatigue and diarrhoea. These effects are generally transient, occur early in treatment, and can often be obviated by careful determination and regulation of the dosage.

Pharmaceutical precautions Dantrium capsules should be stored at room temperature.

Suitable containers are polypropylene, natural polyethylene, amber polyethylene, or amber glass bottles.

Legal category POM.

Package quantities Dantrium capsules 25 mg and Dantrium capsules 100 mg are supplied in containers of 100 capsules.

Further information The duration and intensity of skeletal muscle relaxation in patients on Dantrium is related to the dosage and blood levels. The mean biological half-life of Dantrium is about nine hours after a 100 mg dose.

Studies specifically designed to determine compatibility with diazepam and phenobarbitone revealed that neither of these drugs appears to affect Dantrium metabolism.

Product licence numbers

Dantrium capsules 25 mg 0364/0015
Dantrium capsules 100 mg 0364/0016

DANTRIUM* INTRAVENOUS ▼

Presentation Dantrium Intravenous is available as a sterile, lyophilized orange powder which is a mixture of 20 mg dantrolene sodium, 3000 mg mannitol and sufficient sodium hydroxide to yield a pH of approximately 9.5 when reconstituted with 60 ml of water for injection BP.

Uses Dantrium Intravenous is indicated for the treatment of malignant hyperthermia. It is for intravenous use only.

In isolated muscle preparations, dantrolene sodium uncouples the excitation and contraction of skeletal muscle, probably by interfering with the release of calcium from the sarcoplasmic reticulum.

In the malignant hyperthermia syndrome, evidence points to an intrinsic abnormality of muscle tissue. It has been postulated that 'triggering agents' (i.e. skeletal muscle relaxants and inhalation anaesthetics) induce a sudden rise in myoplasmic calcium, either by preventing the sarcoplasmic reticulum from accumulating calcium adequately, or by accelerating its release. This rise in myoplasmic calcium activates the acute catabolic processes common to the malignant hyperthermia crisis.

Dantrolene sodium may prevent the increases in myoplasmic calcium and the acute catabolism within the muscle cell by interfering with the release of calcium from the sarcoplasmic reticulum to the myoplasm. Thus the physiological, metabolic and biochemical changes associated with the crisis may be reversed or attenuated.

Dosage and administration As soon as the malignant hyperthermia syndrome is recognised all anaesthetic agents should be discontinued. An initial Dantrium Intravenous dose of 1 mg/kg should be given rapidly. If the physiological and metabolic abnormalities persist or reappear, this dose may be repeated up to a cumulative dose of 10 mg/kg. Clinical experience to date has shown that the average dose of Dantrium Intravenous required to reverse the manifestations of malignant hyperthermia has been 2.5 mg/kg. If a relapse or recurrence occurs, Dantrium Intravenous should be readministered at the last effective dose.

Contra-indications, warnings, etc Precautions:

1. In some subjects as much as 10 mg/kg of Dantrium Intravenous has been needed to reverse the crisis. In a 70 kg man this dose would require approximately 36 vials. Such a volume has been administered in approximately one and a half hours.

2. Because of the high pH of the intravenous formulation of Dantrium, care must be taken to prevent extravasation of the intravenous solution into the surrounding tissues.

3. **Pregnancy:** The safety of Dantrium Intravenous in pregnant women has not been established; it should be given only when the potential benefits have been weighed against the possible risk to mother and child.

Warnings: The use of Dantrium Intravenous in the management of malignant hyperthermia is not a substitute for previously known supportive measures. It will be necessary to discontinue the suspect triggering agents, attend to increased oxygen requirements and manage the metabolic acidosis. When necessary institute cooling, attend to urinary output and monitor for electrolyte imbalance.

Side-effects and adverse reactions: No side-effects have been attributed to Dantrium Intravenous. The nature of the emergency and the complexity of concomitant therapy will make it extremely difficult to isolate cause and effect relationships for any of the drugs used. Hepatotoxic reactions have been noted in a small number of subjects given long term oral dantrolene therapy.

Pharmaceutical precautions Each vial of Dantrium Intravenous should be reconstituted by adding 60 ml of water for injection BP, and shaking until the solution is clear. The contents of the vial must be protected from direct light and used within six hours after reconstitution. Protect the reconstituted solutions from temperatures above 30°C and below 15°C.

Unreconstituted product should be protected from light and stored below 30°C.

Legal category POM.

Package quantities Dantrium Intravenous is available in packs of twelve vials each containing 20 mg dantrolene sodium.

Further information Nil.

Product licence number 0364/0030.

FURACIN*

Presentation Furacin Soluble Ointment is a yellow ointment containing 0.2% nitrofurazone in a water-soluble polyethylene glycol base.

Furacin Solution (Sterile) is a yellow liquid containing 0.2% nitrofurazone in a water-miscible vehicle.

Uses Furacin is a broad-spectrum topical antibacterial effective in the presence of blood, pus and serum.

Furacin is indicated in bacterial skin infections including pyodermas, infected dermatoses and infections of wounds, burns and ulcers. Furacin is also of value in the treatment of skin-graft donor sites. Furacin Solution (Sterile) may be used as a bladder irrigant or instillate (diluted 1 in 6 with sterile water for injection).

Dosage and administration Furacin Soluble Ointment: Furacin Soluble Ointment is administered topically. Apply directly to the wound with sterile tongue-depressor or other spatula. Alternatively, melt the ointment in a beaker at a little above body temperature and pour gently on to the wound.

The ointment may also be applied on a gauze dressing. For extensive burned areas, large strips of sterile gauze impregnated with Furacin are often preferred. Bandages may be prevented from absorbing Furacin Soluble Ointment by covering the Furacin impregnated gauze with an impermeable layer, such as jaconet or gauze saturated with petroleum jelly. If bandages stick, remove them by saturating with sterile saline. Dressings may be left undisturbed on burns, cuts and wounds for 7–10 days.

Furacin Solution (Sterile): Furacin Solution (Sterile) may be administered either topically or as an instillate.

Furacin may be used for children at the doctor's discretion.

Contra-indications, warnings, etc Furacin is a contra-indicated in patients with known sensitivity to nitrofurazone.

It is not recommended to continue using Furacin when the infection is cleared.

Furacin Solution and Furacin Ointment should be used with caution in patients with known or suspected renal impairment. The polyethylene glycols in the base can be absorbed through denuded skin and may not be excreted normally by the compromised kidney. This may lead to symptoms of progressive renal impairment.

Side-effects and adverse reactions: Sensitisation to Furacin has been reported. Should this occur, treatment should be discontinued. Since the drug is not used systemically, sensitisation does not carry the implications for the patient that sensitisation to systemic therapy with antibiotics or sulphonamides may.

Pharmaceutical precautions Furacin Soluble Ointment is supplied in aluminium collapsible tubes. The ointment should be stored in light-proof containers and contact with metals other than stainless steel or aluminium should be avoided. There are no other special storage requirements.

Furacin Solution is supplied as a sterile product in 50 ml amber bottles. The product should be protected from light by storing in a dark place. Once opened Furacin Solution (Sterile) should be used immediately. Any unused solution must be discarded.

Legal category POM.

Package quantities Furacin Soluble Ointment is available in tubes of 25 g. Furacin Solution (Sterile) is available in bottles of 50 ml.

Further information Nil.

Product licence numbers

Furacin Soluble Ointment 0364/0013

Furacin Solution (Sterile) 0364/0012

FURADANTIN*

Presentation Furadantin Tablets are yellow in colour and have a pentagonal shape. Each tablet has a break line on one face and the tablet strength is shown on the opposite face. Furadantin Tablets are available in two strengths, containing 100 mg or 50 mg nitrofurantoin.

Furadantin Suspension is a yellow suspension containing 25 mg nitrofurantoin per 5 ml.

Uses Furadantin is a broad-spectrum antibacterial agent, active against the majority of urinary pathogens. It is bactericidal in renal tissue and throughout the urinary tract. After oral administration the nitrofurantoin is rapidly excreted in the urine, up to 45% being unchanged.

Therapeutic: Cystitis, pyelitis, pyelonephritis; also post-operative infections of the genito-urinary tract, particularly after the passage of instruments and after prostatectomy.

Prophylactic and suppressive: As cover for catheterisation or instrumentation of the urinary tract. To prevent reinfection in susceptible individuals.

Dosage and administration Furadantin is administered orally. The dose should be taken with each meal and at bedtime, with food or milk.

In the event of severe nausea the dose may be reduced, but not below the adult equivalent of 200 mg in 24 hours. Should it persist the drug should be withdrawn.

Therapeutic – Adults: Tablets: One 100 mg tablet (or two 50 mg) four times a day.

Suspension: Four 5 ml spoonfuls four times a day.

Therapeutic – Children: Furadantin Suspension or Furadantin Tablets 50 mg may be used. Dosage recommendations for children are given in the table below. It is not recommended to dilute Furadantin Suspension.

Body weight		Average age for weight	Dose to be taken four times daily	
lb	kg		Suspension	50 mg Tablets
10–30	5–13	3–30 months	2.5 ml	$\frac{1}{2}$
30–50	13–23	2½–6 years	5 ml	$\frac{1}{2}$
50–80	23–36	6–11 years	10 ml	1
80–110	36–50	11–14 years	15 ml	1½

Treatment at this dose level for more than 14 days is seldom necessary.

Prophylactic and suppressive: When such therapy is desirable one quarter to one half of the therapeutic dose is suggested.

Contra-indications, warnings, etc Infants under one month should not be given Furadantin.

Furadantin is contra-indicated in patients suffering from anuria or marked oliguria.

A small number of negroes and some people from the Eastern Mediterranean area suffer from a deficiency of glucose-6-phosphate dehydrogenase in their blood cells. In such people, nitrofurantoin in common with many other therapeutic agents may cause haemolysis. This enzyme deficiency is extremely rare in Caucasians. Any sign of haemolysis is an indication to discontinue the drug. Haemolysis ceases when the drug is withdrawn.

Precautions: Furadantin should only be used in pregnancy if considered essential by the physician. Foetal studies in animals with Furadantin do not suggest that it causes any increase in the incidence of congenital abnormalities. This is confirmed by over 28 years of clinical usage. However, it is recognised that caution should be observed when prescribing for the pregnant patient.

Action in event of overdose: Excessive intake would probably cause vomiting. Should overdose occur, stomach wash-out is recommended.

Side-effects: Nausea or vomiting may occur, but this can be minimised or eliminated by taking the drug with food or milk, or adjustment of dosage.

Adverse reactions: Peripheral neuropathy has been reported after treatment with Furadantin but has usually been associated with severe renal impairment and/or prolonged therapy. Should numbness or tingling occur in any part of the body, treatment should be discontinued.

Drug rashes, pyrexia and hepatitis associated with nitrofurantoin therapy have been reported. The hepatitis is of an allergic type and may be associated with antinuclear factor and lymphocyte sensitisation.

A respiratory syndrome with bronchospasm and/or dyspnoea, cough and sometimes chest pain has been reported. These symptoms have occasionally been associated with transitory pulmonary infiltration or pleural effusion.

These adverse reactions to nitrofurantoin therapy are rare.

Antidote: There is no known specific antidote to nitrofurantoin.

Pharmaceutical precautions Furadantin Tablets are supplied in polypropylene containers with polythene pilfer-proof caps. The tablets should be stored in light-proof and preferably moisture-proof containers. There are no other special storage requirements.

Furadantin Suspension is supplied in amber bottles and should be stored in a cool place. The suspension should be protected from light as exposure will cause darkening of the active principle. Because of this, amber bottles should be used in dispensing. The glass should preferably be neutral since discoloration will occur on contact with alkaline materials.

It is not recommended to dilute Furadantin Suspension.

Legal category POM.

Package quantities Furadantin Tablets 100 mg and 50 mg are supplied in packs of 100 and 1,000. Furadantin Suspension is supplied in bottles of 300 ml.

Further information Furadantin is not a sulphonamide; there is no need to increase fluid intake or give alkalis; forcing fluids beyond normal merely dilutes the antibacterial concentration in the urine.

The urine of patients receiving Furadantin may be coloured a dark yellow or brown. This results from the presence of metabolites and is quite harmless.

Product licence numbers

Furadantin Suspension	0364/0010

MACRODANTIN®

Presentation Macrochantin is presented in hard gelatin capsules, and is available in two strengths, containing 100 mg and 50 mg nitrofurantoin macrocrystals.

The 100 mg capsule has an opaque yellow body and cap, and bears the monogram 'Macrochantin' 100.

The 50 mg capsule has an opaque yellow cap, an opaque white body and bears the monogram 'Macrochantin' 50.

Uses Macrochantin is a broad-spectrum antibacterial agent, active against the majority of urinary pathogens. It is bactericidal in renal tissue and throughout the urinary tract.

The nitrofurantoin macrocrystals of Macrochantin are specially formulated. The controlled crystal size is designed to control the speed of absorption and thus reduce the incidence of nausea. Clinical and animal studies indicate that Macrochantin therapy decreases the likelihood of nausea in patients who might experience these symptoms on nitrofurantoin therapy. This special reformulation of nitrofurantoin has not caused any decrease in its bioavailability.

Therapeutic: Cystitis, pyelitis, pyelonephritis; also post-operative infections of the genito-urinary tract, particularly after the passage of instruments and after prostatectomy.

Prophylactic and suppressive: As cover for catheterisation or instrumentation of the urinary tract. To prevent reinfection in susceptible individuals.

Dosage and administration Macrochantin is administered orally. The dose should be taken with each meal and at bedtime, with food or milk.

Therapeutic - Adults: Capsules: One 100 mg capsule (or two 50 mg) four times a day.

Children: For children, Macrochantin 50 mg capsules may be used. Dosage recommendations for children are given in the table below. Treatment at this dose level for more than 14 days is seldom necessary.

Body weight		Average age for weight (years)	Dosage, 50 mg capsules
lb	kg		
30-50	13-23	2½-6	1 capsule twice a day
50-80	23-36	6-11	1 capsule four times a day
80-110	36-50	11-14	2 capsules three times a day

In the event of severe nausea the dose may be reduced, but not below the adult equivalent of 200 mg in 24 hours. Should it persist the drug should be withdrawn.

Prophylactic and suppressive: When such therapy is desirable one quarter to one half of the therapeutic dose is suggested.

Contra-indications, warnings, etc Infants under one month should not be given Macrochantin.

Macrochantin is contra-indicated in patients suffering from anuria or marked oliguria.

A small number of negroes and some people from the Eastern Mediterranean area suffer from a deficiency of glucose-6-phosphate dehydrogenase in their blood cells. In such people, nitrofurantoin in common with many other therapeutic agents may cause haemolysis. This enzyme deficiency is extremely rare in Caucasians. Any sign of haemolysis is an indication to discontinue the drug. Haemolysis ceases when the drug is withdrawn.

Precautions: Macrochantin should only be used in pregnancy if considered essential by the physician. Foetal studies with the active ingredient nitrofurantoin, do not suggest that Macrochantin causes any increase in the incidence of congenital abnormalities. This is confirmed by over 28 years of clinical use of nitrofurantoin. However it is recognised that caution should always be observed when prescribing for the pregnant patient.

Action in event of overdosage: Excessive intake would probably cause vomiting. Should overdosage occur stomach wash-out is recommended.

Side-effects: Nausea or vomiting may occur, but this can be minimised or eliminated by taking the drug with food or milk, or adjustment of dosage.

Adverse reactions: Peripheral neuropathy has been reported after treatment with nitrofurantoin but has usually been associated with severe renal impairment and/or prolonged therapy. Should numbness or tingling occur in any part of the body, treatment should be discontinued.

Drug rashes, pyrexia and hepatitis associated with nitrofurantoin therapy have been reported. The hepatitis is of an allergic type and may be associated with antinuclear factor and lymphocyte sensitisation.

A respiratory syndrome with bronchospasm and/or dyspnoea, cough and sometimes chest pain has been reported. These symptoms have occasionally been associated with transitory pulmonary infiltration or pleural effusion.

These adverse reactions to nitrofurantoin therapy are rare.

Antidote: There is no known specific antidote to nitrofurantoin.

Pharmaceutical precautions Macrochantin Capsules are supplied in polypropylene containers with polythene pilfer-proof caps. The capsules should be stored in light-proof and preferably moisture-proof containers. There are no other special storage requirements.

Legal category POM.

Package quantities Macrochantin Capsules 100 mg and 50 mg are supplied in containers of 100.

Further information Macrochantin is not a sulphonamide: there is no need to increase fluid intake or give alkalis; forcing fluids beyond normal merely dilutes the antibacterial concentration in the urine.

The urine of patients receiving Macrochantin may be coloured a dark yellow or brown. This results from the presence of metabolites and is quite harmless.

Macrochantin Capsules 100 mg 0364/0006

PSORADRATE CREAM*

Presentation Psoradrate cream is a smooth textured, unperfumed, bland, yellow cream containing 0.1%

dithranol BP or 0.2% dithranol BP in a specially formulated powder-in-cream base which includes stabilised, hypermolar urea to assist percutaneous transportation of the active ingredient.

Uses Psoradrate cream is indicated for the treatment of subacute and chronic psoriasis. In addition, Psoradrate 0.1% is indicated for the treatment of psoriasis of the scalp.

Dosage and administration Wash affected areas well, dry thoroughly and apply directly to the lesions twice daily. Treatment should be continued until the raised lesions have disappeared and the skin is smooth. Occlusive dressings should not be used because they may increase the incidence of staining and stinging on normal skin. For use on the scalp, shampoo and dry hair, then rub Psoradrate 0.1% into the lesions, preferably at night. Remove the next morning with shampoo.

Contra-indications, warnings, etc Psoradrate cream is contra-indicated in pustular psoriasis.

The active ingredient of Psoradrate cream, dithranol, may cause a tingling or stinging sensation when applied to skin or lesions. It is irritant to the eyes. If contact occurs wash out immediately with a neutral solution. Exercise care when applying to the face and intertriginous areas. Skin staining may occur and clothing may occasionally be discoloured. For external use only.

Pharmaceutical precautions Store in a cool place. Shelf life: two years. Keep out of reach of children.

Legal category POM.

Package quantities Psoradrate is available in tubes of 30 g and 100 g.

Further information Before using creams containing high concentrations of dithranol it is advisable to establish the patient's tolerance. In cases in which tolerance has not been established, treatment of psoriatic lesions should be commenced with a low concentration of dithranol, namely Psoradrate 0.1%. If the patient's skin can tolerate Psoradrate 0.1% cream, but the lesions appear resistant, then treatment should be changed to Psoradrate 0.2% cream to aid the clearance of the lesions. If, however, the patient is known to have a high tolerance to dithranol then therapy can be commenced using Psoradrate 0.2% cream.

Use of a descaling agent such as salicylic acid is not necessary with Psoradrate creams. The creams are absorbed into the skin and the inconvenience of removing the applications is avoided. Relapse rate with dithranol therapy has been reported as being less than that seen with steroids. Stains on clothes can be removed with a solvent such as trichloroethylene. Psoradrate cream does not contain lanolin or parabens.

Psoradrate Cream 0.2% 0364/0031

VIVONEX* STANDARD

Presentation Vivonex Standard is an off-white, unflavoured water-soluble powder. The contents of one packet supply 300 kilocalories (1.256 MJ) and the following:

	<i>Grams</i>	<i>% by weight</i>
Available nitrogen in the form of pure amino acids (amino acid content 6.18 g)	0.98	1.22
Fat as highly purified safflower oil (80% as triglyceride of linoleic acid)	0.435	0.54
Carbohydrate as glucose solids	69.0	86.3

Caloric contribution:

Amino acids 8.2%

Fat 1.3%

Carbohydrate 90.5%

Six packets of Vivonex Standard supply 5.88 g of available nitrogen, 2.61 g fat, 414 g carbohydrate and the vitamins, amino acids and minerals shown in the following table.

<i>Vitamins</i>	<i>Per 80 g packet</i>	<i>In six 80 g packets</i>
Vitamin A (Retinol) IU	833.33	5,000
Vitamin D ₂ (Ergocalciferol) IU	66.67	400
Vitamin E IU	5	30
Vitamin C (Ascorbic acid) mg	10	60
Folic Acid mg	0.07	0.4
Vitamin B ₁ (Thiamine) mg	0.25	1.5
Vitamin B ₂ (Riboflavin) mg	0.28	1.7
Nicotinamide mg	3.33	20
Vitamin B ₆ mg	0.33	2
Vitamin B ₁₂ mcg	1	6
Biotin mg	0.05	0.3
Pantothenic Acid mg	1.67	10
Vitamin K mcg	11.17	67
Choline mg	12.28	73.7

Amino acids

<i>Essential amino acids</i>	<i>% total amino acids</i>	<i>g/6 packets</i>
L-Isoleucine	4.55	1.69
L-Leucine	7.20	2.67
L-Lysine	5.41	2.00
L-Methionine	4.66	1.73
L-Phenylalanine	5.18	1.93
L-Threonine	4.55	1.69
L-Tryptophan	1.41	0.52
L-Valine	5.02	1.86
Total	37.98	14.09

<i>Non-essential amino acids</i>	<i>% total amino acids</i>	<i>g/6 packets</i>
L-Alanine	4.85	1.80
L-Arginine	8.87	3.29
L-Aspartic acid	10.35	3.84
L-Glutamine	17.07	6.33
Glycine	7.91	2.93
L-Histidine	2.21	0.82
L-Proline	6.48	2.41
L-Serine	3.34	1.24
L-Tyrosine	0.94	0.35
Total	62.02	23.01

Electrolytes

<i>Cations</i>	<i>In normal dilution 80 g in 300 ml m-equiv/100 ml</i>	<i>In powder form</i>	
		<i>mg/80 g packet</i>	<i>mg/6 packets</i>

Potassium	2.99	351.5	2,109
Calcium	2.77	166.7	1,000
Magnesium	1.83	66.67	400
Manganese	0.00567	0.468	2.81
Iron	0.0358	3	18
Copper	0.0035	0.333	2
Zinc	0.0255	2.5	15
<i>Anions</i>	<i>m-equiv/100 ml</i>	<i>mg/80 g packet</i>	<i>mg/6 packets</i>
Chloride	5.185	551.6	3,310
Phosphate (as P)	5.40	166.6	1,000
Acetate	0.0296	5.25	31.5
Iodide	0.000066	0.025	0.150
Gluconate	1.69	991.8	5,950
Sorbate	0.447	149	894

Six packets also contain 0.25 mcg Cobalt as Vitamin B₁₂.

Uses Vivonex Standard provides total enteral nutrition which requires minimal digestion and produces no exogenous residue.

It is indicated in the treatment of bowel fistulae, bowel obstruction, Crohn's disease, ulcerative colitis and other disorders of the digestive organs or of the alimentary tract where elemental nutrition with low fat and minimal residue is considered of value.

Vivonex Standard can be used to ensure a clear operative field for bowel surgery or diagnostic procedures. Use of Vivonex Standard pre-operatively can help to ensure that the negative nitrogen balance, often seen post-operatively in undernourished patients, is minimised or avoided.

Post-operatively Vivonex Standard provides a balanced, low residue, low fat, milk free nutritional regimen to maintain a positive nitrogen balance during the catabolic phase, and to simplify nursing during the recovery period. Vivonex Standard may also be used as an alternative to parenteral feeding and as supplementary feeding when a high energy intake is required.

Dosage and administration *Dosage - Adults:* Six packets (1,800 kilocalories) a day, which may be increased if thought necessary to meet the nutritional demands of some patients.

Children: Vivonex Standard may be given to children. However, when used for children under 10 years it may be necessary to adjust the quantity of Vivonex Standard consumed daily to meet the projected nutritional requirements for the patient involved.

Vivonex Standard may be used as a nutritional source in both infants and children. Vivonex Standard contains no cystine, a semi-essential amino acid in the newborn. The amount of Vivonex Standard required to maintain weight and nitrogen balance will vary with each individual.

As the recommended daily intake varies with the age of the infant or child, daily administration of a mineral and vitamin supplement may be necessary to meet individual needs, particularly when Vivonex Standard is used as the sole source of nutrition for more than a few days.

If Vivonex Standard, in standard dilution, is administered as the sole source of nutrition, additional fluid will be required to avoid dehydration.

Administration: Vivonex Standard may be administered orally, as a drink or frozen, or by nasogastric or enteric tube.

Contra-indications, warnings, etc

Contra-indications: There are no contra-indications.

Warnings: Vivonex Standard must not be administered parenterally.

Precautions: Because of the high caloric contribution from carbohydrates some depleted individuals may manifest elevated blood sugar levels requiring insulin for regulation. Vivonex Standard should be used with care in diabetics.

The electrolyte content of Vivonex Standard is based on requirements of normal individuals and may be excessive for patients with electrolyte imbalance.

Use during pregnancy or lactation may require supplementary vitamins and minerals.

Use for children under 10 years may require adjustment of the daily consumption to meet the projected nutritional requirements for the patient involved.

Most patients should be started slowly on Vivonex Standard. Begin the first day with Vivonex Standard at half strength and on the second day the patient may be tried with the standard dilution. Each 300 ml feed must be sipped slowly over at least a one hour period for best results.

Action in event of overdosage: Overdosage is unlikely to occur and would result in vomiting and/or diarrhoea. Should overdosage occur, stop feeding Vivonex Standard and give water to avoid dehydration.

Pharmaceutical precautions *Storage:* When packaged in cartons or in packets, Vivonex Standard should be stored in a cool, dry place.

In normal dilution Vivonex Standard is a perishable liquid. A full day's supply may be prepared at one time and stored in the refrigerator for up to 24 hours. Shake the liquid briefly before serving. Never leave at room temperature for more than a few hours.

Diluents: In no circumstances should Vivonex Standard be mixed with less than 250 ml (8½ oz) of water per 80 g packet.

Legal category POM.

Package quantities Vivonex Standard is supplied in cartons of six packets, each packet containing 80 g soluble powder.

Further information Vivonex Standard is a complete, elemental, minimal residue nutrition requiring little digestion. It is absorbed in the upper small intestine, leaving the lower bowel at rest. Vivonex Standard leaves no exogenous residue. On a Vivonex Standard-only regimen faecal volume and frequency are much reduced, and a bowel action every five to seven days is to be expected.

In severe catabolic states the Vivonex Standard

formulation may fail to achieve positive nitrogen balance. In such circumstances Vivonex HN is recommended.

Adult patients receiving Vivonex Standard do not normally require any additional supplements.

Vivonex Standard is available solely as an unflavoured powder. To ensure patient acceptance when feeding Vivonex orally, the drink should be served flavoured and chilled. Vivonex Flavour sachets are available in Orange, Strawberry, Beef Broth and Tomato flavours. Beef Broth and Tomato flavours may be blended with warm water. Alternatively, Vivonex may be flavoured using commercially available carbonated or still soft drinks.

Where accurate nutritional control is required, allowance must be made for any added calorie or mineral content, and for indigestible matter.

Vivonex Standard may be administered as a slow continuous naso-enteric infusion via any suitable naso-enteric feeding system.

For details of prescribing under the ACBS ruling see the current edition of MIMS.

Product licence number 0364/0014.

VIVONEX* HN

Presentation Vivonex HN is an off-white, unflavoured water-soluble powder. The contents of one packet supply 300 kilocalories (1.256 MJ) and the following:

	Grams	% by weight
Available nitrogen in the form of pure amino acids (amino acid content 13.31 g)	2.00	2.5
Fat as highly purified safflower oil (80% as triglyceride of linoleic acid)	0.261	0.326
Carbohydrate as glucose solids	63.3	79.1

Caloric contribution.

Amino acids	17.7%
Fat	0.78%
Carbohydrate	81.5%

Ten packets of Vivonex HN supply 20.0 g of available nitrogen, 2.61 g fat, 633g carbohydrate and the vitamins, amino acids and minerals shown in the table below.

Vitamins	Per 80 g packet	In ten 80 g packets
Vitamin A (Retinol) IU	500	5,000
Vitamin D ₂ (Ergocalciferol) IU	40	400
Vitamin E IU	3	30
Vitamin C (Ascorbic acid) mg	6	60
Folic Acid mg	0.04	0.4
Vitamin B ₁ (Thiamine) mg	0.15	1.5
Vitamin B ₂ (Riboflavine) mg	0.17	1.7
Nicotinamide mg	2	20
Vitamin B ₆ mg	0.2	2
Vitamin B ₁₂ mcg	0.6	6
Biotin mg	0.03	0.3
Pantothenic Acid mg	1	10
Vitamin K mcg	6.7	67

Manganese	0.00341	0.281	2.81
Iron	0.02148	1.8	18
Copper	0.002098	0.2	2
Zinc	0.0153	1.5	15
<i>Anions</i>	<i>m-equiv/100 ml</i>	<i>mg/80 g packet</i>	<i>mg/10 packets</i>
Chloride	5.24	557.3	5,573
Phosphate (as P)	3.16	100	1,000
Acetate	0.0178	3.15	31.5
Iodide	0.000039	0.015	0.15
Gluconate	0.967	565.7	5,657
Sorbate	0.268	89.2	892

Ten packets also contain 0.25 mcg Cobalt as Vitamin B₁₂.

Uses Vivonex HN provides total enteral nutrition for patients who have increased calorie and nitrogen requirements. Vivonex HN requires minimal digestion and produces no exogenous residue.

Use of Vivonex HN prior to major surgery can help to avoid or minimise negative nitrogen balance.

The high nutritional value and minimal residue properties of Vivonex HN make it useful in the management

of malabsorption states, short bowel syndrome, bowel fistulae, bowel obstruction, Crohn's disease, ulcerative colitis and as a treatment following total gastrectomy; or for other conditions of the digestive organs or of the alimentary tract where elemental nutrition with low fat, minimal residue and a high nutritional contribution is considered of value.

Post-operatively Vivonex HN provides a balanced, low residue, low fat, milk free nutritional regimen to maintain a positive nitrogen balance during the catabolic phase and to simplify nursing during the recovery period.

Vivonex HN, which may be given orally or by continuous nasogastric infusion may be used as an alternative to parenteral feeding and/or as supplementary feeding when a high intake is required.

Dosage and administration *Dosage – Adults:* Ten packets (3,000 kilocalories) a day, which may be increased if thought necessary to meet the nutritional demands of some patients.

Children: Vivonex HN may be given to children. However, when used for children under 10 years it may be necessary to adjust the quantity of Vivonex HN consumed daily to meet the projected nutritional requirements for the patient involved.

Vivonex HN may be used as a nutritional source in both infants and children. Vivonex HN contains no cystine, a semi-essential amino acid in the newborn. The amount of Vivonex HN required to maintain weight and nitrogen balance will vary with each individual.

As the recommended daily intake varies with the age of the infant or child, daily administration of a mineral and vitamin supplement may be necessary to meet individual needs, particularly when Vivonex HN is used as the sole source of nutrition for more than a few days.

If Vivonex HN, in standard dilution, is administered as the sole source of nutrition, additional fluid will be required to avoid dehydration.

Administration: Vivonex HN may be administered by nasogastric or enteric tube or orally, as a drink or frozen.

Contra-indications, warnings, etc

Contra-indications: There are no contra-indications.

Warnings: Vivonex HN must not be administered parenterally.

Precautions: Because of the high caloric contribution from carbohydrates some depleted individuals may manifest elevated blood sugar levels requiring insulin for regulation. Vivonex HN should be used with care in diabetics.

The electrolyte content of Vivonex HN is based on requirements of normal individuals and may be excessive for patients with electrolyte imbalance.

Use during pregnancy or lactation may require supplementary vitamins and minerals.

Use for children under 10 years may require adjustment of the daily consumption to meet the projected nutritional requirements for the patient involved.

Most patients should be started slowly on Vivonex HN. Details of a suggested regimen for initiating tube feeding are given on the package insert inside each carton of Vivonex HN.

For oral feeding a similar regimen should be adopted to allow the body to adjust to liquid nutrition. It is essential that each 300 ml feed be sipped slowly over a period of at least an hour.

Action in event of overdosage: Overdosage is unlikely to occur and would result in vomiting and/or diarrhoea.

Should overdosage occur, stop feeding Vivonex HN and give water to avoid dehydration.

Pharmaceutical precautions *Storage:* When packaged in cartons or in packets, Vivonex HN should be stored in a cool, dry place.

In normal dilution, Vivonex HN is a perishable liquid. A full day's supply may be prepared at one time and stored in the refrigerator for up to 24 hours. Shake the liquid briefly before serving. Never leave at room temperature for more than a few hours.

Diluents: In no circumstances should Vivonex HN be mixed with less than 250 ml (8½ oz) of water per 80 g packet.

Legal category POM.

Package quantities Vivonex HN is supplied in cartons of 10 packets, each packet containing 80 g soluble powder.

Further information Vivonex HN is a complete, elemental, minimal residue, nutrition requiring little digestion. It is completely absorbed in the upper small intestine, leaving the lower bowel at rest. Vivonex HN leaves no exogenous residue. On a Vivonex HN only regimen faecal volume and frequency are much reduced, and a bowel action every five to seven days is to be expected.

When severe catabolic states do not exist the Vivonex Standard formulation may be the preparation of choice.

Adult patients receiving Vivonex HN do not normally require any additional supplements.

Vivonex HN is available solely as an unflavoured powder. To ensure patient acceptance when feeding Vivonex HN orally, the drink should be served flavoured and chilled. Vivonex Flavour sachets are available in Orange, Strawberry, Beef Broth and Tomato flavours. Beef Broth and Tomato flavours may be blended with warm water. Alternatively, Vivonex HN may be flavoured using commercially available carbonated or still soft drinks.

Where accurate nutritional control is required, allowance must be made for any added calorie or mineral content, and for indigestible matter.

Vivonex HN may be administered as a slow continuous nasoenteric infusion via any suitable naso-enteric feeding system.

HUMAN ACTRAPID* ▼
HUMAN MONOTARD* ▼

Presentation Human Actrapid (Neutral Insulin Injection) is a neutral solution of Human Insulin (emp).

Human Monotard (Insulin Zinc Suspension) is a neutral suspension of amorphous (30%) and crystalline (70%) Human Insulin (emp).

When shaken it appears white and cloudy.

Both Human Monocomponent insulin preparations are available in strengths of 40 and 80 i.u./ml.

Uses The treatment of insulin-requiring diabetic patients. May be advantageous in the treatment of insulin induced fat atrophy, insulin allergy, insulin resistance and labile diabetes, and when intermittent short term therapy is required.

Human Actrapid may be used for all diabetics who require a quick and intense-acting insulin, e.g. in emergencies such as diabetic hyperglycaemic coma, during surgery and severe infection in diabetics, and in the management of pregnant diabetics.

Dosage and administration The dosage of insulin is determined by the physician according to the needs of the patient.

Human Actrapid may be given by injection or infusion, subcutaneously, intramuscularly or intravenously. It has a duration of action of some $\frac{1}{2}$ to 8 hours and its maximum effect is exerted between 2 $\frac{1}{2}$ and 5 hours after injection. Owing to its strong early effect the interval between the injection and the following meal should be 15–30 minutes.

Human Monotard may be given by subcutaneous or intramuscular injection. It may be given once or, more commonly, twice daily and may be combined with Human Actrapid. Human Monotard has a duration of action of some 2 $\frac{1}{2}$ to 22 hours and its maximum effect is exerted between 7 and 15 hours after injection.

Human Monocomponent insulin preparations may be admixed in the syringe and the injection given immediately.

Infusion pumps: Human Actrapid may be used in most infusion pumps; however, peristaltic pumps (roller pumps) are not suitable for use with Human Actrapid due to the risk of precipitation. The pump manufacturers instructions regarding type, strength and administration of insulin must be followed.

Human Monotard must not be used in insulin infusion pumps.

Use in pregnancy: It is essential to maintain continuous good control of the insulin requiring diabetic patient throughout pregnancy. In the insulin-treated (gestational or insulin dependent) pregnant diabetic patient the insulin requirements usually fall in the first trimester and increase during the second and third trimester.

Contra-indications, warnings, etc

Contra-indications: Insulin is contra-indicated in hypoglycaemia.

Precautions: On transfer from porcine monocomponent

insulins or other highly purified porcine insulins to Human Monocomponent insulin, no change in dosage is anticipated other than the routine adjustments made in order to maintain stable diabetic control.

Patients currently stabilised on mixed species or bovine insulin may require a dosage adjustment dependent upon the dosage, purity, species and formulation of the insulin(s) currently administered. Variations in glycaemic control may occur and adjustments in therapy should be made under the guidance of a physician.

Insulin resistant patients receiving over 100 units daily should be referred to hospital for transfer.

The addition of corticosteroids, oral contraceptives or thyroid hormone replacement therapy is likely to lead to an increase in insulin requirements. The addition of a beta-adrenergic blocking agent or a monoamine oxidase inhibitor, (MAOI) may also necessitate an adjustment of insulin dosage.

Side-effects: Lipodystrophy, insulin resistance and hypersensitivity reactions have been associated with insulin therapy, but the incidence and severity of these unwanted effects is minimal with the Human Monocomponent insulins. Severe local or generalised allergic reactions require immediate treatment and, in some cases, desensitisation may be necessary.

Overdosage: In the event of an overdose, glucose should be given orally if the patient is conscious. The unconscious patient should be treated with glucose intravenously or rectally and glucagon may be administered intramuscularly or subcutaneously.

Pharmaceutical precautions Human Monocomponent insulins should be stored between 2°C and 8°C. They should not be exposed to excessive heat or sunlight, neither should they be frozen. The vial in use may be kept at room temperature (max. 25°C) for one month. Human Monocomponent insulins have a shelf life of two years.

Legal category P.

Package quantities 10 ml glass vials of 40 i.u./ml or 80 i.u./ml.

ACTRAPID* MC
SEMITARD* MC
RAPITARD* MC
MONOTARD* MC
LENTARD* MC
ULTRATARD* MC

Presentation *Actrapid MC* (Neutral Insulin Injection BP) is a neutral solution of porcine MC insulin.

Semitard MC (Insulin Zinc Suspension Amorphous BP) is a neutral suspension of amorphous porcine MC insulin.

Rapitard MC (Biphasic Insulin Injection BP) is a neutral suspension comprising porcine MC insulin (25%) in solution and crystalline bovine MC insulin (75%).

Monotard MC (Insulin Zinc Suspension BP) is a neutral suspension of amorphous (30%) and crystalline (70%) porcine MC insulin.

Lentard MC (Insulin Zinc Suspension BP) is a neutral suspension of amorphous porcine MC insulin (30%) and crystalline bovine MC insulin (70%).

Ultratard MC (Insulin Zinc Suspension Crystalline BP) is a neutral suspension of crystalline bovine MC insulin.

When shaken the suspensions appear white and cloudy. All the above insulins are available in strengths of 40 and 80 i.u./ml.

Uses The treatment of insulin-requiring diabetic patients.

Actrapid MC may be used for all diabetics who require a quick and intense-acting insulin, e.g. in emergencies such as diabetic hyperglycaemic coma, during surgery and severe infections in diabetics and in the management of pregnant diabetics.

MC insulins may be advantageous in the treatment of insulin-induced fat atrophy, insulin allergy, insulin resistance and labile diabetes, and when intermittent short-term therapy is required.

Dosage and administration The dosage of insulin is determined by the physician according to the needs of the patient.

MC insulin preparations may be admixed in the syringe and the injection given immediately.

Actrapid MC may be given by injection or infusion, subcutaneously, intramuscularly or intravenously, and may be combined with other MC insulins.

Actrapid MC has a duration of action of some $\frac{1}{2}$ to 7 hours and its maximum effect is exerted between 2 $\frac{1}{2}$ and 5 hours after injection. Owing to its strong early effect, the interval between the injection and the following meal should be 15 to 30 minutes.

Suspensions may be given by subcutaneous or intramuscular injection.

Semitard MC is usually given twice daily and may be combined with Actrapid MC. Semitard MC has a duration of action of some 1 $\frac{1}{2}$ to 16 hours and its maximum effect is exerted between 5 and 10 hours after injection.

Rapitard MC is indicated as a once daily injection in patients with stable diabetes of moderate severity, especially when a fairly strong early effect is desired. Rapitard MC may also be used for the regulation of unstable severe diabetes on a twice daily injection regime. Rapitard MC has a duration of action of some 1 to 22 hours and its maximum effect is exerted between 4 and 12 hours after injection. Owing to its strong early effect the interval between the injection and the following meal should be approximately 30 minutes.

Monotard MC is given once or, more commonly, twice daily and may be combined with Actrapid MC. Monotard MC has a duration of action of some 2 $\frac{1}{2}$ to 22 hours and its maximum effect is exerted between 7 and 15 hours after injection.

Lentard MC as a once daily injection is an appropriate routine for 24 hour regulation of blood sugar in patients with stable diabetes of moderate severity. Lentard MC has a duration of action of some 2 $\frac{1}{2}$ to 24 hours and its

maximum effect is exerted between 7 and 15 hours after injection.

Ultratard MC can be used as a once daily injection in mild (type 2) diabetes when diet alone fails to produce good control and may also be combined with Actrapid MC in the management of type 1 or type 2 diabetes. Ultratard MC has a duration of action of some 4 to 36 hours and its maximum effect is exerted between 10 and 30 hours after injection.

Infusion pumps: Actrapid MC may be used in most infusion pumps; however, peristaltic pumps (roller pumps) are not suitable for use with Actrapid MC due to the risk of precipitation. The pump manufacturer's instructions regarding type, strength and administration of insulin must be followed.

Suspensions must not be used in insulin infusion pumps.

Use in pregnancy: It is essential to maintain continuous good control of the insulin-requiring diabetic patient throughout pregnancy. In the insulin-treated (gestational or insulin-dependent) pregnant diabetic patient the insulin requirements usually fall in the first trimester and increase during the second and third trimesters.

Contra-indications, warnings, etc *Contra-indications:* Insulin is contra-indicated in hypoglycaemia.

Precautions: Patients transferred from conventional (predominantly bovine) insulins may require a smaller dosage. The dosage reduction may occur immediately after transfer or gradually over a period of weeks or months. In order to reduce the risk of hypoglycaemia the patient and the physician should be aware of the possibility that the insulin requirement may be reduced. If the daily insulin dosage is below 40 i.u. the risk is considered minimal. However, when higher dosages are required, stricter supervision of the patient is necessary and possibly a 20% reduction should be made initially on transfer to the porcine MC insulins. Transfer to mixed species or bovine MC insulins may be associated with a smaller reduction in dosage. Insulin-resistant patients receiving over 100 units daily should be referred to hospital for transfer.

The addition of corticosteroids, oral contraceptives or thyroid hormone replacement therapy is likely to lead to an increase in insulin requirements. The addition of a beta-adrenergic blocking agent or a monoamine oxidase inhibitor (MAOI) may also necessitate an adjustment of insulin dosage.

Side-effects: Lipodystrophy, insulin resistance and hypersensitivity reactions have been associated with insulin therapy, but the incidence and severity of these unwanted effects is minimal with the MC insulins. Severe localised or generalised allergic reactions require immediate treatment and, in some cases, desensitisation may be necessary.

Overdosage: In the event of an overdose, glucose should be given orally if the patient is conscious. The unconscious patient should be treated with glucose intravenously or rectally, and glucagon may be administered intramuscularly or subcutaneously.

Pharmaceutical precautions MC insulins should be stored between 2°C and 8°C. They should not be exposed to excessive heat or sunlight, neither should they be frozen. MC insulins have a shelf life of two years. Expiry date is printed on the package.

Legal category P.

Package quantities 10 ml glass vials of 40 i.u./ml and 80 i.u./ml.

GLUCAGON NOVO

Presentation Glucagon Novo is available as the hydrochloride in lyophilised freeze-dried form with accompanying diluent in two pack sizes:

1 mg – a vial containing glucagon hydrochloride 1 mg (1 i.u.) and lactose 107 mg, with a pre-sterilised disposable syringe containing Water for Injections 1.1 ml as diluent.

10 mg – a vial containing glucagon hydrochloride 10 mg (10 i.u.) and lactose 140 mg, with a vial containing 10 ml of diluent (comprised of glycerin 230 mg, methyl hydroxybenzoate 10 mg and propyl hydroxybenzoate 1.5 mg as preservatives, Water for Injections to 10 ml).

Uses Glucagon Novo is indicated in the treatment of severe hypoglycaemic reactions which may occur following insulin or oral therapy in the management of diabetic patients, or during insulin shock therapy in psychiatric patients. Glucagon Novo is also recommended as an adjunct for use in examinations of the gastro-intestinal tract by radiography or endoscopy.

Dosage and administration *Adults and children:*

1. Treatment of severe hypoglycaemic reactions. Dissolve the lyophilised glucagon in the accompanying diluent. Give 0.5 to 1 mg (0.5 to 1 i.u.) of Glucagon Novo by subcutaneous, intramuscular or intravenous injection. If the patient does not awaken within 20 minutes, intravenous glucose must be given. When the patient responds, administer oral carbohydrate to restore the liver glycogen and prevent secondary hypoglycaemia.

2. Insulin shock therapy. Dissolve the lyophilised glucagon in the accompanying diluent. After one hour of coma, give 0.5 to 1 mg (0.5 to 1 i.u.) of Glucagon Novo by subcutaneous, intramuscular or intravenous injection. If the patient does not awaken within 20 minutes, intravenous glucose must be given. When the patient responds, administer oral carbohydrate to restore the liver glycogen and prevent secondary hypoglycaemia.

In very deep states of coma, intravenous glucose may be given concurrently with Glucagon Novo.

3. Radiography and endoscopy of the gastro-intestinal tract. Dissolve the lyophilised glucagon in the accompanying diluent. The dosage required to dilate the stomach and duodenum and inhibit motility may range from 0.2 mg (0.2 i.u.) to 2 mg (2 i.u.) intravenously.

There is considerable variation in response between patients, depending on the technique of administration, so that no general dosage recommendations can be made but there is an upper dose limit of 2 mg.

The initial dilation and inhibition of motility lasts about 5 to 15 minutes, after which glucagon acts as a hurrying agent producing rapid transit of the barium through the small bowel to the lower gut.

Contra-indications, warnings, etc *Contra-indications:* Glucagon Novo is contra-indicated in phaeochromocytoma, insulinoma and glucagonoma.

Precautions: Caution must be observed if Glucagon Novo is used in diabetic patients as an adjunct in radiography or endoscopy of the gastro-intestinal tract. Since glucagon is a protein, there is a theoretical possibility of hypersensitivity.

Side-effects: Glucagon is relatively free of adverse effects except for occasional reports of nausea and vomiting which tends to be dose-related.

Pharmaceutical precautions Glucagon as the dry substance has a shelf life of two years when stored at room temperature below 25°C. Expiry date is printed on the package.

1 mg pack: The solution should be prepared immediately prior to use.

10 mg pack: The solution should preferably be prepared immediately prior to use but may be stored in a refrigerator at 4°C for up to one week. If fibril formation takes place or if solid particles are present in the solution the solution should not be used.

Legal category POM.

Package quantities A single dose pack consisting of a glass vial containing glucagon hydrochloride 1 mg (1 i.u.) in lyophilised freeze-dried form, with a pre-sterilised disposable syringe containing diluent. A multiple dose pack consisting of a glass vial containing glucagon hydrochloride 10 mg (10 i.u.) in lyophilised freeze-dried form, with a glass vial containing 10 ml diluent.

Further information *Sole distributors:* Farillon Limited, Bryant Avenue, Romford, Essex. RM3 0PJ. Tel: Ingrebourne 71136.

1 mg	0542/0016
10 mg	0542/0017

TRYPURE*

Presentation Trypure contains pure crystalline trypsin stabilised by the addition of a small quantity of inert calcium salt.

It is available in three presentations:

50 mg (dry powder) – a vial containing sterile trypsin 50 mg with a vial containing 15 ml diluent (each 1 ml comprised of sodium chloride 9 mg and methyl hydroxybenzoate/propyl hydroxybenzoate 1 mg).

5 g (dispersible powder) – a spray vial containing dispersed trypsin powder 5 g (trypsin 50 mg) with a spray vial containing 45 ml lidocaine solution 2% (each 1 ml comprised of lidocaine hydrochloride 20 mg, cetrimide 1 mg and sodium chloride 4.7 mg).

25 g (spray) – a pressurised aerosol can containing trypsin-freon suspension 25 g (trypsin 250 mg) with a spray vial containing 45 ml lidocaine solution 2% (each

1 ml comprised of lidocaine hydrochloride 20 mg, cetrimide 1 mg and sodium chloride 4.7 mg).

Uses Action: Trypsin is a proteolytic enzyme which directly promotes the hydrolysis of proteins in necrotic tissue, thereby supplementing the proteolytic enzymes of the body in the enzymatic debridement of wounds, ulcers, cavities and exudates.

Trypure has a proteolytic activity of approximately 4,000 NF units/mg equivalent to 25 Anson units.

Indications: The Trypure preparations are indicated for local use in the debridement of open wounds, ulcers or cavities, and for the liquefaction of coagulated blood and exudates.

Dosage and administration Approximately 50 mg Trypure (contained in the dry powder, dispersible powder or 5 bursts of one second from the spray) should be applied locally to each 100–200 sq cm of wound surface, but smaller doses should be used for small cavities. One application daily is normally sufficient.

After re-constitution of the dry powder by addition of the diluent, the resulting solution is suitable for application to surface wounds either directly or by means of a compress soaked in the solution. The dry powder in solution can also be used for instillation or local injection.

When using the dispersible powder or spray pack, pre-treatment of the area by spraying with the lidocaine solution 2% will reduce any transient pain experienced after the application of Trypure, and provide the moisture necessary to activate the Trypure.

The spray pack, which should be shaken before use and applied at a distance of 15 cm from the wound surface, may be used for larger or less accessible areas.

After the application of Trypure, the area of the lesion must be covered with a wet compress and a waterproof dressing. The compress should be kept moist at all times by re-soaking with physiological saline.

Wound debridement should always be carried out prior to each application of Trypure.

Contra-indications, warnings, etc *Contra-indications:* Known allergy to trypsin. Trypure powder in solution should never be given intravenously and should not be given by inhalation to patients prone to bronchospasm or asthma.

The dispersible powder and spray should not be used for inhalation therapy or for the treatment of nasal or oral lesions.

Precautions: Care should be taken to avoid getting Trypure into the eyes or nose. If this should happen, thorough irrigation of the eyes or nose with running water is indicated.

The spray pack should not be used near an open fire or any other strong source of heat.

Trypure should be used sparingly in ischaemic areas and caution is recommended when treating tuberculous empyema.

Warnings and adverse effects: The application of Trypure may be associated with transient pain which can be reduced by pre-treatment of the area with lidocaine solution 2% (available with the dispersible powder and spray pack).

Allergic or histamine-like reactions to trypsin occur rarely and respond to antihistamine therapy.

Pharmaceutical precautions *Storage:* Trypure powder in solution is stable for 24 hours at room temperature, and for one week at 4°C (in a refrigerator).

The dry powder has a shelf life of 3 years when stored at 15°C and the dispersible powder and spray pack each have a shelf life of 2 years when stored at this temperature. Expiry date is printed on the package.

The aerosol can in the spray pack should not be punctured or incinerated.

Compatibility: The use of Trypure can be combined, when necessary, with local or systemic antibiotic therapy. There is no evidence to suggest that Trypure is incompatible with hydrogen peroxide (when mixed at neutral pH), chlorhexidine and cetrimide solutions, whereas Trypure has been shown to be incompatible with potassium permanganate, chloramine, sodium hypochlorite, silver nitrate and iodine/iodide solutions.

BOLVIDON*

Presentation Yellow, film-coated, bi-convex tablets 6.5 mm in diameter, coded CT4 on one side and 'Organon' on the reverse side, each containing 10 mg mianserin hydrochloride.

White, film-coated, bi-convex tablets 7 mm in diameter, coded CT6 on one side and 'Organon' on the reverse side, each containing 20 mg mianserin hydrochloride.

White, film-coated, bi-convex tablets 8 mm in diameter, coded CT7 on one side and 'Organon' on the reverse side, each containing 30 mg mianserin hydrochloride.

Uses Symptoms of depressive illness.

Dosage and administration The tablets should be swallowed whole without chewing.

Adults: Bolvidon can be taken either in divided doses or as a single dose at night. Treatment should usually commence with 30 mg or 40 mg per day for the first few days. The effective daily dosage usually lies between 30 mg and 90 mg. Divided daily doses up to 200 mg are well tolerated.

It is often advantageous to maintain antidepressant treatment for several months after initial clinical improvement has occurred.

Elderly: Not more than 30 mg a day initially. The dose should be increased with caution under close supervision. A lower than the normal maintenance dose may be sufficient to produce a satisfactory clinical response.

Children: Not recommended.

Contra-indications, warnings, etc

Contra-indications: Mania. Severe liver disease. During breast feeding. Breast feeding should be discontinued if treatment with Bolvidon is considered essential.

Do not use during pregnancy unless there are compelling reasons. There is no evidence of safety in human pregnancy. Animal studies have not shown hazard.

Precautions: Care should always be taken in patients with recent myocardial infarction or heart block. Serious cardiotoxic effects appear to be rare at therapeutic dosage, even in patients with pre-existing cardiac disease, recent myocardial infarction or cardiac insufficiency.

The elderly are less liable to experience adverse reactions such as agitation, confusion and postural hypotension with Bolvidon than with tricyclics or bridged tricyclics, but all anti-depressant therapy should be used with caution in this group of patients.

Patients posing a high suicidal risk require close initial supervision.

Avoid if possible in patients with epilepsy. When treating patients with diabetes, hepatic or renal insufficiency, normal precautions should be exercised and the dosages of any concurrent therapy kept under review.

Patients with narrow angle glaucoma or symptoms suggestive of prostatic hypertrophy should also be monitored even though anticholinergic side-effects are not anticipated with Bolvidon therapy.

There are indications that Bolvidon, like other antidepressants, may precipitate hypomania in susceptible subjects with bipolar affective illness.

Bolvidon may potentiate the central nervous depressant action of alcohol.

If surgery is necessary during Bolvidon therapy the anaesthetist should be informed of the treatment being given.

Drug interactions: Bolvidon should not be given concurrently with, or within two weeks of cessation of therapy with monoamine oxidase inhibitors.

Phenytoin plasma levels should be monitored in patients treated concurrently with Bolvidon.

Interactions with sympathomimetic agents have not been reported, and are unlikely.

Clinical experience has shown that Bolvidon does not interact with the anti-hypertensives bethanidine, clonidine, hydralazine, guanethidine and propranolol. Nevertheless, the monitoring of blood pressure is recommended for those patients receiving concurrent anti-hypertensive therapy.

Concurrent anticoagulant therapy of the coumarin type (e.g. warfarin) is also permissible, but close additional monitoring procedures should be carried out.

Warnings and adverse effects: As improvement may not occur during the first 2-4 weeks of treatment, patients should be closely monitored during this period.

It is advisable to maintain treatment with Bolvidon for several months after initial clinical improvement.

The most commonly occurring side effect is drowsiness, particularly during the first few days of treatment. Patients should be warned of the possible hazard in driving or operating machinery. Any drowsiness may be potentiated by alcohol.

Serious adverse effects are uncommon. A small number of cases of bone marrow depression, usually presenting as a neutropenia, generally reversible on stopping treatment, have been reported. If a patient develops symptoms of infection, e.g. fever, sore throat or stomatitis, during treatment with Bolvidon, treatment must be stopped and a full blood count obtained.

Jaundice, usually mild, hypomania and convulsions have also been reported at therapeutic dosage and under such circumstances treatment should be withdrawn.

Additional adverse effects that may occur include breast disorders (gynaecomastia, nipple tenderness and non-puerperal lactation), dizziness, postural hypotension, polyarthralgia, skin rash, sweating and tremor.

Psychotic manifestations, including mania and paranoid delusions, may be exacerbated during antidepressant therapy.

The following adverse effects although not reported with Bolvidon can occur with tricyclics and bridged tricyclics: interference with sexual function; withdrawal symptoms in adults; withdrawal symptoms (e.g. neuromuscular irritability) in neonates whose mothers received tricyclic or bridged tricyclic antidepressants during pregnancy.

Overdosage: There is no specific antidote. Treatment is by gastric lavage with appropriate supportive therapy. Symptoms of overdosage are normally confined to prolonged sedation.

Cardiac arrhythmias, convulsions, severe hypotension and respiratory depression are unlikely to occur.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities

Bolvidon tablets 10 mg are supplied in push-through PVC/foil blister strips of 30 tablets. Packed in cartons containing three strips (90 tablets).

Bolvidon tablets 20 mg are supplied in push-through PVC/foil blister strips of 21 tablets. Packed in cartons containing three strips (63 tablets).

Bolvidon tablets 30 mg are supplied in push-through PVC/foil blister strips of 14 tablets. Packed in cartons containing three strips (42 tablets).

All strengths also available in Securitainers of 100 and 500 tablets.

Further information Bolvidon is a tetracyclic antidepressant which is structurally distinct from classical tricyclics and from bridged tricyclics, this difference is reflected in its pharmacology. Bolvidon is a potent histamine and serotonin antagonist with little influence on cholinergic receptors, selective for pre-synaptic alpha-2 rather than post-synaptic alpha-1 receptors. Bolvidon has no effect on serotonin re-uptake and only affects noradrenaline re-uptake in vitro. In vivo Bolvidon increases noradrenaline turnover. Bolvidon produces fewer and milder side effects than the tricyclics and bridged tricyclics especially in terms of anticholinergic effects and effects on the cardiovascular system. Bolvidon does not cause the severe complications in overdosage associated with tricyclics and bridged tricyclics, e.g. severe cardiac arrhythmias, respiratory depression, convulsions and coma.

10 mg tablets – 0065/0031R

20 mg tablets – 0065/0057R

30 mg tablets – 0065/0061R

COTAZYM®

Presentation Dark green gelatine capsules, containing pancreatic enzymes in powder form; administered by sprinkling on the food, or in milk.

Active ingredients: Lipase – not less than 14,000 FIP units; amylase – not less than 10,000 FIP units; protease – not less than 500 FIP units.

Uses Each Cotazym Capsule contains sufficient enzymes to digest 17 g dietary fat, 34 g dietary protein and 40 g dietary starch.

Indicated in pancreatic enzyme deficiency states, including fibrocystic disease, post-gastrectomy malabsorption, chronic pancreatitis, pancreatic carcinoma, and steatorrhoea.

Dosage and administration Cotazym is given in sufficient quantity to cover every gram of fat in the entire daily diet, including between-meal snacks. When dosage is calculated on the fat-digesting power of the lipase (17 g dietary fat per capsule) there will normally be sufficient trypsin and amylase to adequately cover protein and starch digestion. An average diet would take about 6 capsules a day to cover it. The capsules are opened and the contents sprinkled onto the food, or in milk; the total dose should be divided and taken throughout the day with each meal and each snack.

Contra-indications, warnings, etc There are no known contra-indications.

Pharmaceutical precautions Store in a cool dry place between 2° and 15°C and protect capsules from light.

Legal category P.

Package quantities Bottles of 100 capsules.

Further information Because Cotazym has an assayed lipase activity, the dosage required to digest a known amount of dietary fat can be easily determined.

Product licence number 0065/5054.

COTAZYM B®

Presentation Round, bi-convex, white, film-coated tablets, diameter 11 mm.

Active ingredients: Pancreas powder, lipase activity 5,400 FIP units; cellulase 2.25 Wallerstein units; and Ox Bile Extract NF XI equivalent to 30 mg cholic acid, in each tablet.

Uses Cotazym B is an enzyme preparation in tablet form. It has a broad spectrum of digestive activity and is valuable in the treatment of a variety of disorders of the gastro-intestinal tract, whether these are due to a permanent or temporary enzyme deficiency or even due to intolerance of certain foods, especially those of a fatty nature.

Dosage and administration Cotazym B Tablets should not be chewed; they should always be swallowed at mealtimes, with water if necessary. An average dose of 6 tablets daily (2 with each meal) will digest 50 g fat, 100 g protein, 250 g starch and 480 mg cellulose, which in a balanced diet represents about 2,000 calories.

Contra-indications, warnings, etc

Contra-indications: There are no known contra-indications.

Precautions and warnings: It will generally be necessary to restrict the fat intake in the diet. In patients with impaired renal function attention should be paid to the volume and acidity of the urine.

Pharmaceutical precautions Store in a cool dry place between 2 and 15°C.

Legal category P.

Package quantities Boxes of 120 tablets, individually foil-stripped.

Further information Nil.

Product licence number 0065/5023.

DECA-DURABOLIN*

Presentation Nandrolone Decanoate Injection BP. 1 ml ampoules in three strengths, 25 mg, 50 mg and 100 mg per ml: 1 ml Orgaject* disposable syringes 25 mg and 50 mg per ml.

Uses Deca-Durabolin is a long-acting anabolic agent with a duration of effect lasting up to three weeks. Indicated in all conditions requiring a powerful and prolonged anabolic or anti-catabolic stimulus. It can be used as an adjunct to specific anti-anaemic therapy in the treatment of certain refractory anaemias.

Dosage and administration Deca Durabolin should only be administered by deep injection into the gluteus maximus muscle.

Adults: For most indications 25–50 mg every three weeks.

Children: Up to 0.4 mg per kg every three weeks.

In the anaemias associated with chronic renal failure and in malignant disease treated with adjuvant chemotherapy, the following doses are recommended.

Adults: 100–200 mg weekly.

Children: 0.75–1.5 mg/kg weekly.

Contra-indications, warnings, etc

Contra-indications: Contra-indicated in pregnancy, carcinoma of prostate or testes, and mammary carcinoma in the male.

Precautions and warnings: Hypercalcaemia or hypercalciuria may develop either spontaneously or as a result of therapy in patients with certain tumours, especially in mammary carcinoma, hypernephroma and bronchial carcinoma. If hypercalcaemia or hypercalciuria develop during such treatment the preparation should be discontinued and appropriate measures should be taken to normalise calcium levels.

Patients with myocardial, hepatic or renal dysfunction, migraine, epilepsy, hypertension or a history of coronary artery disease should be observed carefully, since anabolic steroids may cause sodium and water retention.

Alterations in glucose tolerance may occur, requiring surveillance for latent diabetes, and possible changes in control for diabetic patients. The need for insulin or other anti-diabetic drugs may be reduced.

Skeletal maturation should be followed carefully when treating children, since anabolic steroids in high dosages may accelerate this process.

Adverse Reactions: Deca-Durabolin is usually free from virilising properties at the recommended dose levels. Larger doses than those recommended, prolonged treatment and/or too frequent administration may cause virilisation in some sensitive women. Hoarseness of the voice may be the first symptom of vocal change which may lead to irreversible lowering of the voice. If signs of virilisation, particularly lowering of the voice, develop, treatment should be discontinued in circumstances where the clinical condition is not sufficiently severe to warrant continuation. Other signs are acne, hirsutism, and increase of libido in women. There may be increased frequency of erections and phallic enlargement in prepubertal males, and clitoral hypertrophy and increase of pubic hair may occur in girls.

Prolonged treatment, use of high dosages, and/or too frequent administration may also increase the risk of amenorrhoea in women and inhibition of spermatogenesis in the male – both conditions probably resulting

from an inhibition of the release of gonadotrophins from the pituitary.

Occasionally, changes have been seen in the outcome of liver function tests, such as serum transaminases, in patients treated with Deca Durabolin. Treatment, however, need not be interrupted on this account. The changes appear to be reversible after discontinuation of the treatment.

Interactions: Although only one possible case of interaction with an oral anti-coagulant has been observed, it is advisable to check the prothrombin time regularly when Deca Durabolin is used in conjunction with such an agent.

Concurrent administration of liver enzyme inducing drugs such as rifampicin, barbiturates, phenylbutazone or phenytoin may decrease the effect of Deca Durabolin.

Pharmaceutical precautions Protect from light. Store at room temperature (15° to 25°C). After storage at lower temperatures precipitation of the arachis oil vehicle may occur. By heating the ampoules at 100°C for a few minutes or at 40°C for one hour the solution will become clear. The precipitation and rewarming does not affect the activity of the injection.

Legal category POM.

Package quantities 25 mg per ml: 1 ml ampoules in boxes of 3 and 1 ml Orgaject* Disposable Syringes singly.

50 mg per ml: 1 ml ampoules in boxes of 3 and 1 ml Orgaject* Disposable Syringes singly.

100 mg per ml: 1 ml ampoules in boxes of 3.

Further information Unlike the orally active anabolics (c-17 α -alkylated steroids) Nandrolone does not cause cholestatic jaundice and liver damage.

DURABOLIN*

Presentation Nandrolone Phenylpropionate Injection BP. 1 ml ampoules and 1 ml Orgaject* Disposable Syringes 25 mg per ml and 1 ml Orgaject* Disposable Syringes 50 mg per ml.

Active ingredient: Nandrolone Phenylpropionate BP 25 mg or 50 mg per ml.

Uses Durabolin is an anabolic agent with medium duration of action. The effects of a single intramuscular injection are apparent within a few hours and last for 7–10 days. Indicated in all conditions requiring a prolonged anabolic or anti-catabolic stimulus.

Dosage and administration Durabolin should only be administered by deep injection into the gluteus maximus muscle.

Adults: For most indications, 25–50 mg once weekly. In acute renal failure, doses as high as 50 mg daily may be required. Higher dosage may also be necessary in mammary carcinoma in females.

Children: Dosage should be adjusted to the weight of the child, and should not exceed 1 mg per kg per month.

Contra-indications, warnings, etc

Contra-indications: Contra-indicated in pregnancy, car-

cinoma of prostate or testes, and mammary carcinoma in the male.

Precautions and warnings: Hypercalcaemia or hypercalciuria may develop either spontaneously or as a result of therapy in patients with certain tumours, especially mammary carcinoma, hypernephroma and bronchial carcinoma. If hypercalcaemia or hypercalciuria develop during such treatment the preparation should be discontinued and appropriate measures should be taken to normalise calcium levels.

Patients with myocardial, hepatic or renal dysfunction, migraine, epilepsy, hypertension or a history of coronary artery disease should be observed carefully, since anabolic steroids may cause sodium and water retention.

Alterations in glucose tolerance may occur, requiring surveillance for latent diabetes, and possible changes in control for diabetic patients. The need for insulin or other anti-diabetic drugs may be reduced.

Skeletal maturation should be followed carefully when treating children, since anabolic steroids in high dosages may accelerate this process.

Adverse Reactions: Durabolin is usually free from virilising properties at the recommended dose levels. Larger doses than those recommended, prolonged treatment and/or too frequent administration may cause virilisation in some sensitive women. Hoarseness of the voice may be the first symptom of vocal change which may lead to irreversible lowering of the voice. If signs of virilisation, particularly lowering of the voice, develop, treatment should be discontinued in circumstances where the clinical condition is not sufficiently severe to warrant continuation. Other signs are acne, hirsutism, and increase of libido in women. There may be increased frequency of erections and phallic enlargement in prepubertal males, and clitoral hypertrophy and increase of pubic hair may occur in girls.

Prolonged treatment, use of high dosages, and/or too frequent administration may also increase the risk of amenorrhoea in women and inhibition of spermatogenesis in the male – both conditions probably resulting from an inhibition of the release of gonadotrophins from the pituitary.

Occasionally, changes have been seen in the outcome of liver function tests, such as serum transaminases, in patients treated with Durabolin. Treatment, however, need not be interrupted on this account. The changes appear to be reversible after discontinuation of the treatment.

Interactions: It is advisable to check the prothrombin time regularly when Durabolin is used in conjunction with an oral anti-coagulant.

Concurrent administration of liver enzyme inducing drugs such as rifampicin, barbiturates, phenylbutazone or phenytoin may decrease the effect of Durabolin.

Pharmaceutical precautions Protect from light. Store at room temperature (15° to 25°C). After storage at lower temperatures precipitation of the arachis oil vehicle may occur. By heating the ampoules at 100°C for a few minutes or at 40°C for one hour the solution will become clear. The precipitation and rewarming does not affect the activity of the injection.

GESTANIN*

Presentation Round, flat, white tablets, diameter 6.5 mm, code-marked 'GK4' one side, with 'Organon' and a star on the reverse side.

Active ingredient: Allylestrenol 5 mg per tablet.

Uses Indicated where threatened abortion, recurrent abortion and failure of nidation is due to lack of endogenous progestogen.

Dosage and administration *Recurrent abortion:* As soon as pregnancy has been diagnosed, 1–2 tablets daily. Continue treatment for at least 16 weeks.

Threatened abortion: 3 tablets daily for at least five to seven days. If necessary, daily dosage may be increased and the treatment period extended, without risk.

Failure of nidation: 2–4 tablets daily from the sixteenth to the twenty-sixth day of each cycle until conception is achieved. Thereafter, 2 tablets daily for at least 16 weeks.

Contra-indications, warnings, etc

Contra-indications: Use in patients with a history of, or existent thromboembolic disorders, or with mammary or genital carcinoma.

Use in patients with impaired liver function, or with active liver disease.

Use in patients with undiagnosed, irregular vaginal bleeding.

Precautions and warnings: A decreased glucose tolerance may occur in diabetic patients on this treatment and their control must be carefully supervised. Patients receiving treatment with a progestogen should be kept under regular surveillance, and should have a thorough physical examination regularly. This product should be discontinued before elective surgery or during enforced bed rest.

Pharmaceutical precautions Protect tablets from light.

Legal category POM.

Package quantities Bottles of 100 tablets.

Further information Premature termination of pregnancy often follows a fall in placental hormone levels. Gestanin stimulates secretion of the endogenous placental hormones essential for the maintenance of pregnancy. Gestanin is non-virilising and is well tolerated.

Product licence number 0065/5030.

HYDROCORTISONE SODIUM SUCCINATE

Presentation Hydrocortisone Sodium Succinate Injection BP. In two strengths – ampoules and vials 100 mg; vials 500 mg. The white freeze-dried material contains sodium phosphates 16.6 mg per 100 mg hydrocortisone as buffering agents.

Active ingredient: Hydrocortisone Sodium Succinate equivalent to 100 mg or 500 mg hydrocortisone.

Uses Hydrocortisone Sodium Succinate is a readily soluble ester of hydrocortisone with the same actions as unesterified hydrocortisone. Indicated in the management of emergencies amenable to intensive corticosteroid therapy, such as status asthmaticus, acute adrenal crisis, cardiogenic, haemorrhagic or septic shock. Also valuable in shock states due to anaphylaxis, burns, severe diarrhoea or where the cause of shock is obscure, and in the treatment of ulcerative colitis.

Dosage and administration Rapid intravenous injection of massive doses of corticosteroids may sometimes cause cardiovascular collapse; the injection should therefore be given over a period of not less than 10 minutes.

For immediate use as a single injection of 500 mg dissolve the contents in 10 ml of Water for Injections BP.

Adults: Status asthmaticus: Initially, 500 mg intravenously; this dose should be repeated four to five hours later or followed by an infusion of 500 mg every four hours. Potassium supplements may be needed.

Acute adrenal crisis: 250 mg intravenously, then approximately 250 mg every 12 hours by intravenous infusion.

Shock states, e.g. cardiogenic, bacteraemic, anaphylactic, burns, etc.: 500 mg intravenously, repeated as necessary every two to six hours, either intravenously or by infusion.

Ulcerative colitis: 100 mg, dissolved in 120 ml saline and administered as a rectal drip.

Children: The usual daily dose is 6–10 mg/kg body weight but in life-threatening states 50 mg/kg body weight may be required.

Contra-indications, warnings, etc

Contra-indications: Systemic corticosteroids are generally contra-indicated in patients with Cushing's Syndrome, gastro-intestinal ulcers, systemic fungal infections or acute bacterial or viral infections, particularly ocular herpes infections, active tuberculosis and acute psychosis.

When pregnancy is present or suspected, the benefits of the use of corticosteroids should be weighed against the possible hazards to the foetus.

While on corticosteroid therapy, patients should not be vaccinated against smallpox. Other immunisation procedures should be undertaken under close observation as corticosteroid therapy may interfere with active immunisation due to the immuno-suppressive effects of corticosteroids.

No contra-indications exist when corticosteroids, in a large single dose, are used in conditions where life is endangered.

Precautions and warnings:

Patients currently on corticosteroid therapy or those who have been on such treatment within the previous year may require special control measures if involved in anaesthesia, surgical procedures and other stress. These special control measures usually involve increased dosage of rapidly-acting corticosteroids and are indicated before, during and after the stressful situation.

Withdrawal of corticosteroids should always be gradual and related to the duration of use and should be carried out under strict medical supervision. Withdrawal may result in acute rebound exacerbation of disease, acute adrenocortical insufficiency, polyarteritis.

The uses of corticosteroids in the presence of other disorders (e.g. diabetes mellitus, tuberculosis, amoebiasis, osteoporosis, a history of mental disorders, cardiomyopathy, hypertension and renal insufficiency) or of drugs with specific actions (e.g. hypoglycaemics), impinging on the effects of corticosteroids, may result in imbalance of control.

Corticosteroid administration will result in certain effects, the severity, significance and extent of which vary with the dosage and duration of treatment and the particular corticosteroid used. These include disturbance in electrolyte balance, mineral metabolism, glucose metabolism and gluconeogenesis, nitrogen depletion, diminished lymphoid tissue and immune response, inhibition of pituitary function, Cushingoid Syndrome, increase in blood coagulability, diminished inflammatory response.

Growth and development of children on prolonged corticosteroid therapy should be carefully observed (see 'adverse reactions').

Corticosteroid therapy is non-specific, suppresses the symptoms and signs of disease and enhances susceptibility to infections; appropriate anti-microbial therapy should accompany corticosteroid therapy when necessary.

Corticosteroids appear in breast milk in very small quantities. Mothers taking high doses of corticosteroids should be advised not to breast feed.

Adverse reactions: Adverse reactions associated with short-term corticosteroid therapy in high doses are uncommon.

The major adverse reactions with prolonged corticosteroid therapy are: peptic ulcers, acute pancreatitis, hypokalaemia, infections, suppression of growth in children, CNS effects (ranging from euphoria to frank psychotic manifestations), suppression of ACTH secretion and decreased reactive ability of the adrenal cortex, osteoporosis, ocular effects, negative nitrogen and calcium balance, atrophy of the skin, impaired wound healing, myopathy, diabetogenic effect, sodium and water retention (oedema), hypertension, and development of a Cushingoid state (e.g. 'moon-face', striae, 'central obesity', 'buffalo hump', supraclavicular fat pads, acne, hirsutism).

Pseudotumor cerebri (benign increased intracranial pressure) has been reported in some children receiving systemically administered corticosteroids for prolonged periods; vomiting and papilloedema tend to subside with reduction of dosage.

Anaphylactic reactions, such as urticaria and bronchospasm, have occurred, although very rarely, after intravenous administration of corticosteroids, particularly in patients with a history of hypersensitivity to drugs or allergy to food. If such anaphylactic reactions occur, the following measures are advisable; immediate intravenous injection of adrenaline (0.1–0.5 mg dependent on bodyweight), intermittent positive-pressure ventilation and administration of aminophylline.

When large doses are given intravenously, a transitory burning or tingling sensation, mainly in the perineal area, is often experienced.

Interactions: Concomitant use of corticosteroids and diuretics may result in an enhanced potassium loss.

Concurrent administration of liver enzyme inducing drugs such as rifampicin,ephedrine, barbiturates, phenylbutazone or phenytoin may decrease corticosteroid effects, while if anticoagulants are given with the

corticosteroid, adjustment of dosage of the former is usually necessary.

Salicylates should be used cautiously in conjunction with corticosteroids in hypoprothrombinaemia.

If patients undergoing long term therapy with corticosteroids are concomitantly given salicylates, any reduction in corticosteroid dosage should be made with caution, since cases of salicylate intoxication under these conditions have been reported.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities

100 mg strength: Boxes of 10 vials or ampoules, with 2 ml ampoules of solvent (Water for Injections BP)

500 mg strength: Boxes of 10 vials, without solvent.

Further information Hydrocortisone Sodium Succinate has a marked effect on inflammatory and allergic conditions. Its solubility in water makes it suitable for administration by intravenous injection or infusion in the treatment of acute emergencies. In such emergencies, massive doses can produce dramatic improvement; the required blood cortisol levels are best achieved with an initial intravenous injection, followed by further injections or infusions, and accompanied by appropriate supportive therapy.

Compatibility with Infusion Fluids:

Hydrocortisone Sodium Succinate is compatible with the following i.v fluids:

Dextrose 2½% to 10% in water or normal saline or half-strength saline, invert sugar 5% or 10% in water or saline, lactated Ringer's injection, Ringer's injection, sodium chloride injection. Sodium lactate (1/6M) injection.

500 mg 0065/5071

MARVELON* ▼

Presentation White, round, biconvex tablets, coded TR5 on one side and ORGANON on the reverse side. Each tablet contains: 150 micrograms desogestrel and 30 micrograms ethinylestradiol.

Uses Oral contraception.

Dosage and administration The tablets are to be taken orally, without chewing, at the same time each day, e.g. at the time of the evening meal.

First course: One tablet daily for 21 days, starting on the first day of the menstrual cycle, with a tablet which is marked with the appropriate day of the week.

Subsequent courses: Each subsequent course is started after seven tablet-free days have followed the preceding course.

Post-partum use: After delivery or abortion, oral contraception should start on the first day of the first spontaneous menstruation. Since the first post-partum ovulation may precede the first bleeding, another method of non-hormonal contraception should therefore be used in the interval between childbirth and the fourteenth tablet-taking day of the first course. In general, Marvelon appears to have no adverse effect on lactation and the excretion of desogestrel in the milk is negligible. However, suppression of lactation may occur when administration is started immediately post-partum.

Changing from another oral contraceptive: Women may change without inconvenience from any other oral contraceptive to Marvelon. The first Marvelon tablet is taken on the first day of the withdrawal bleeding, provided that this bleeding starts with seven days of taking the last tablet. If no bleeding has occurred within seven days of taking the last tablet of the previous oral contraceptive, pregnancy should first be ruled out.

When a patient is changing from a combined oral contraceptive the pack must first be completed before administration of Marvelon commences.

When a patient is taking a combined oral contraceptive which has a 28 day tablet regime and which contains inactive tablets for the last few days (as opposed to a progestogen-only pill), withdrawal bleeding will occur during the inactive phase. When changing to Marvelon the tablets should be started on the first day of this bleeding and the remaining tablets of the previous oral contraceptive may be discarded.

When changing from a progestogen-only pill to Marvelon, the first tablet should be taken on the first day of bleeding, even if this occurs before completion of the previous pack.

Any remaining progestogen-only pills should be discarded.

Additionally, another method of non-hormonal contraception should be used for the first fourteen days.

Contra-indications, warnings, etc

Contra-indications:

- Thrombophlebitis, thrombo-embolic processes, or a history of these conditions.
 - Known or suspected oestrogen-dependent tumours e.g. mammary, genital carcinoma.
 - Undiagnosed irregular vaginal bleeding.
 - Acute or chronic liver disease or history of liver disease where the liver function tests have failed to return to normal. Jaundice or history of jaundice in pregnancy. Rotor syndrome or Dubin-Johnson syndrome.
- N.B.* The use of oral contraceptives is not contra-indicated in patients with a history of hepatitis whose liver functions are normal.
- Porphyria.
 - Cerebrovascular or cardiovascular disease.
 - Hyperlipoproteinaemia, especially in the presence of other risk factors which may indicate a predisposition to cerebrovascular or cardiovascular disorders.
 - A history during pregnancy of severe pruritis, herpes gestationis or a deterioration of otosclerosis.
 - Pregnancy or suspected pregnancy

Precautions and warnings: Pregnancy must be excluded before treatment is started. Whenever there is a reason to suspect pregnancy during treatment, this possibility must be investigated by the physician. If pregnancy has been confirmed, tablet-intake must be discontinued immediately.

Physical examination should precede the prescribing of any oral contraceptive and should be repeated regularly. Special attention should be paid to duration of the cycle, body weight, blood pressure, heart, breasts, pelvic organs, legs and skin.

A cervical smear should be taken at regular intervals.

The physician must be aware that the reliability of oral contraceptives is reduced when a tablet has been forgotten or if gastro-intestinal disturbances occur. If a

patient forgets to take a tablet, it should be taken as soon as possible, continuing thereafter with the normal dosage scheme. The omission of two or more tablets may significantly reduce the reliability of the method. In illness with vomiting or diarrhoea, failure to absorb the tablets can reduce contraceptive reliability.

In addition, the concomitant use of other drugs may interact with oral contraceptives. (See 'Interactions').

If efficacy is in doubt because of the above factors then additional non-hormonal contraceptive precautions are necessary and these should be continued until the next withdrawal bleeding. In some women using an oral contraceptive the amount and/or duration of blood loss during the withdrawal bleeding may be reduced. Occasionally the withdrawal bleeding may even fail to occur. When the aforementioned circumstances are excluded, pregnancy is unlikely and there is no reason to discontinue the use of Marvelon.

However, if during the use of Marvelon the previously regular withdrawal bleeding suddenly fails to occur, pregnancy should be excluded. When there are any reasons to suspect pregnancy, successive pregnancy tests may need to be performed at intervals of one week. While awaiting the outcome of these tests, the patient should be advised to discontinue tablet-intake and to use another method of non-hormonal contraception.

If any signs of thrombo-embolic processes occur, tablet-intake must be discontinued immediately.

The risk of arterial thrombosis associated with combined oral contraceptives increases with age and this risk is aggravated by cigarette smoking. The use of combined oral contraceptives by women in the older age group, especially those who are cigarette smokers, should therefore be discouraged and alternative methods advised.

Oral contraceptive preparations may increase the risk of thrombosis, and this should be taken into account when surgery is to be performed in patients using these preparations. Where possible, oral contraceptives should be discontinued approximately six weeks prior to elective surgery and not recommenced until the patient has recovered and is mobile.

Pre-existing uterine fibromyomata may increase in size under the influence of oestrogens, and if this is observed administration of the preparation should be discontinued.

Since the glucose tolerance may diminish during the use of oral contraceptives, diabetic patients should be monitored closely.

Patients with myocardial or renal disease, varicose veins, epilepsy, migraine, asthma, or a disease exacerbated by pregnancy require careful monitoring since fluid retention has been observed during continued use of oral contraceptives.

Young women whose cycles are not yet stabilised may experience irregular cycle control in the initial stages of oral contraceptive therapy.

Some women experience an increase in blood pressure during pregnancy and/or during oral contraceptive use. In these women the blood pressure should be checked regularly. In case of serious hypertension, further administration of the preparation must be withheld.

Hepatic cell adenomas have been reported in women on oral contraceptive preparations. The adenoma may present itself as an abdominal mass or with the signs and symptoms of an acute abdomen. A bleeding hepatic cell adenoma should be considered if the patient has abdominal pain or evidence of intra-abdominal bleeding.

Patients wearing contact lenses should be advised that they may experience some discomfort.

The use of oral contraceptive preparations may influence the results of certain laboratory tests.

Oral contraceptives have no significant influence on adreno-cortical function. The ACTH function test for the adrenal cortex remains unchanged. The reduction in corticosteroid excretion and the elevation of plasma corticosteroids are due to an increased cortisol-binding capacity of the plasma proteins.

The response to metyrapone is less pronounced in women receiving oral contraceptives and is thus similar to the response during pregnancy.

The radio-iodine uptake shows that thyroid function is unchanged. There is a rise in serum protein-bound iodine, similar to that in pregnancy and during the administration of oestrogens. This is due to the increased capacity of the plasma proteins for binding thyroid hormones, rather than to any change in glandular function. In women taking oral contraceptives, the content of protein-bound iodine in blood serum should, therefore, not be used for the evaluation of thyroid function.

Oral contraceptives may accelerate erythrocyte sedimentation in the absence of any disease. This effect is due to a change in the proportion of the plasma protein fractions.

Increases in plasma copper, iron and alkaline phosphatase have also been recorded.

Adverse reactions: During the first months of use of oral contraceptives, irregular bleeding may occur. Experience has shown that this is almost certainly a transient problem, therefore tablet-intake should be continued. If the irregular bleeding is heavy or prolonged, the physician should investigate.

Nausea, vomiting, headache and breast tenderness may be experienced during the initial months of use. These symptoms usually disappear rapidly; if not, the physician should investigate.

There are reports indicating an association between oral contraceptive preparations and the occurrence of cholelithiasis.

During the use of oral contraceptives, body weight may increase. Experience has shown that body weight stabilises after some time and in some cases can easily be controlled by a suitable diet.

During the use of oral contraceptives fluid retention may occur.

Symptoms such as sudden severe headaches, pains in the chest, visual disturbances, and a swollen arm or leg require immediate medical examination.

If jaundice, which is not necessarily treatment-related, occurs during the use of this preparation, administration must be discontinued immediately.

Chloasma is occasionally seen during the use of oral contraceptives, especially in women with a history of chloasma gravidarum. Women with a tendency to chloasma should avoid exposure to the sun whilst taking this preparation.

In some women who use oestrogen/progestogen preparations, depression may occur. In a number of these women there may be a disturbance of tryptophan metabolism and in such cases the administration of vitamin B₆ might be of therapeutic value.

Interactions: Irregular cycles and reduced reliability of oral contraceptives may occur when these preparations are used concomitantly with liver enzyme inducing drugs such as rifampicin, barbiturates and certain anti-epileptics, or with ampicillin. If no withdrawal bleeding occurs, it is advisable to make sure that these conditions have

not played a contributory role. If they cannot be excluded, the chance of pregnancy is high. In such cases the use of the oral contraceptive preparation should be stopped immediately and diagnosis established.

During this time other forms of non-hormonal contraception should be used.

Overdosage: There have been no reports of serious ill-effects from overdosage, even when a considerable number of tablets have been taken by a small child. In general, it is therefore unnecessary to treat overdosage. However, if overdosage is discovered within two or three hours and is large, then gastric lavage can be safely used.

There are no specific antidotes and further treatment should be symptomatic.

Pharmaceutical precautions Store in a cool, dry place and protect from light.

Legal category POM.

Package quantities Pack of 21 tablets (one month's supply).

Further information Nil.

Product licence number 0065/0071.

MINILYN[®]

Presentation Round, flat, white tablets, diameter 6 mm, code-marked with a circle on one side and Organon on the reverse side. Each tablet contains: Lynoestrenol BP 2.5 mg and Ethinyloestradiol BP 0.05 mg.

Uses Oral contraception.

Dosage and administration The tablets are to be taken orally without chewing, at the same time each day, e.g. at the time of the evening meal.

First course: One tablet daily for 22 days, starting on the first day of the menstrual cycle, with a tablet which is marked with the appropriate day of the week.

Subsequent courses: Each subsequent course is started after six tablet-free days have followed the preceding course; thus, if the 'last tablet' is taken on a Friday, then the first tablet from the next pack is taken on the following Friday.

Post-partum use: After delivery or abortion, oral contraception should start on the first day of the first spontaneous menstruation. Since the first post-partum ovulation may precede the first bleeding, another method of non-hormonal contraception should therefore be used in the interval between childbirth and the fourteenth tablet-taking day of the first course. In general, Minilyn appears to have no adverse effect on lactation and the excretion in the milk is negligible. However, suppression of lactation may occur when administration is started immediately post-partum.

Changing from another oral contraceptive: Women may change without inconvenience from any other oral contraceptive to Minilyn. The first Minilyn tablet is taken on the first day of the withdrawal bleeding, provided that this bleeding starts within six days of taking the last tablet. If no bleeding has occurred within six days of taking the last tablet of the previous oral contraceptive, pregnancy should first be ruled out.

When a patient is changing from a combined oral

contraceptive the pack must first be completed before administration of Minilyn commences.

When a patient is taking a combined oral contraceptive which has a 28 day tablet regime and which contains inactive tablets for the last few days (as opposed to a progestogen-only pill), withdrawal bleeding will occur during the inactive phase. When changing to Minilyn the tablets should be started on the first day of this bleeding and the remaining tablets of the previous oral contraceptive may be discarded.

When changing from a progestogen-only pill to Minilyn the first tablet should be taken on the first day of bleeding, even if this occurs before completion of the previous pack. Any remaining progestogen-only pills should be discarded.

Additionally, another method of non-hormonal contraception should be used for the first fourteen days.

Contra-indications, warnings, etc

Contra-indications:

- Thrombophlebitis, thrombo-embolic processes, or a history of these conditions.
- Known or suspected oestrogen-dependent tumours, e.g. mammary, genital carcinoma.
- Undiagnosed irregular vaginal bleeding.
- Acute or chronic liver disease or history of liver disease where the liver function tests have failed to return to normal. Jaundice or history of jaundice in pregnancy. Rotor syndrome or Dubin-Johnson syndrome.
- N.B.* The use of oral contraceptives is not contra-indicated in patients with a history of hepatitis whose liver functions are normal.
- Porphyria.
- Cerebrovascular or cardiovascular disease.
- Hyperlipoproteinaemia, especially in the presence of other risk factors which may indicate a predisposition to cerebrovascular or cardiovascular disorders.
- A history during pregnancy of severe pruritis, herpes gestationis or a deterioration of otosclerosis.
- Pregnancy or suspected pregnancy.

Precautions and warnings: Pregnancy must be excluded before treatment is started. Whenever there is a reason to suspect pregnancy during treatment, this possibility must be investigated by the physician. If pregnancy has been confirmed, tablet-intake must be discontinued immediately.

Physical examination should precede the prescribing of any oral contraceptive and should be repeated regularly. Special attention should be paid to duration of the cycle, body weight, blood pressure, heart, breasts, pelvic organs, legs and skin.

A cervical smear should be taken at regular intervals.

The physician must be aware that the reliability of oral contraceptives is reduced when a tablet has been forgotten or if gastro-intestinal disturbances occur. If a patient forgets to take a tablet, it should be taken as soon as possible, continuing thereafter with the normal dosage scheme. The omission of two or more tablets may significantly reduce the reliability of the method. In illness with vomiting or diarrhoea, failure to absorb the tablets can reduce contraceptive reliability.

In addition, the concomitant use of other drugs may interact with oral contraceptives. (See 'Interactions'.)

If efficacy is in doubt because of the above factors then additional non-hormonal contraceptive precautions are necessary and these should be continued until the next withdrawal bleeding.

In some women using an oral contraceptive the amount and/or duration of blood loss during the withdrawal bleeding may be reduced. Occasionally the withdrawal bleeding may even fail to occur. When the aforementioned circumstances are excluded, pregnancy is unlikely and there is no reason to discontinue the use of Minilyn. However, if during the use of Minilyn the previously regular withdrawal bleeding suddenly fails to occur, pregnancy should be excluded. When there are any reasons to suspect pregnancy, successive pregnancy tests may need to be performed at intervals of one week. While awaiting the outcome of these tests, the patient should be advised to discontinue tablet-intake and to use another method of non-hormonal contraception.

If any signs of thrombo-embolic processes occur, tablet-intake must be discontinued immediately.

The risk of arterial thrombosis associated with combined oral contraceptives increases with age and this risk is aggravated by cigarette smoking. The use of combined oral contraceptives by women in the older age group, especially those who are cigarette smokers, should therefore be discouraged and alternative methods advised.

Oral contraceptive preparations may increase the risk of thrombosis and this should be taken into account when surgery is to be performed in patients using these preparations. Where possible, oral contraceptives should be discontinued approximately six weeks prior to elective surgery and not recommenced until the patient has recovered and is mobile.

Pre-existing uterine fibromyomata may increase in size under the influence of oestrogens, and if this is observed administration of the preparation should be discontinued.

Since the glucose tolerance may diminish during the use of oral contraceptives, diabetic patients should be monitored closely.

Patients with myocardial or renal disease, varicose veins, epilepsy, migraine, asthma, or a disease exacerbated by pregnancy require careful monitoring since fluid retention has been observed during continued use of oral contraceptives.

Young women whose cycles are not yet stabilised may experience irregular cycle control in the initial stages of oral contraceptive therapy.

Some women experience an increase in blood pressure during pregnancy and/or during oral contraceptive use. In these women the blood pressure should be checked regularly. In case of serious hypertension, further administration of the preparation must be withheld.

Hepatic cell adenomas have been reported in women on oral contraceptive preparations. The adenoma may present itself as an abdominal mass or with the signs and symptoms of an acute abdomen. A bleeding hepatic cell adenoma should be considered if the patient has abdominal pain or evidence of intra-abdominal bleeding.

Patients wearing contact lenses should be advised that they may experience some discomfort.

The use of oral contraceptive preparations may influence the results of certain laboratory tests.

Oral contraceptives have no significant influence on adrenocortical function. The ACTH function test for the adrenal cortex remains unchanged. The reduction in corticosteroid excretion and the elevation of plasma corticosteroids are due to an increased cortisol-binding capacity of the plasma proteins.

The response to metyrapone is less pronounced in women receiving oral contraceptives and is thus similar to the response during pregnancy.

The radio-iodine uptake shows that thyroid function is unchanged. There is a rise in serum protein-bound iodine, similar to that in pregnancy and during the administration of oestrogens. This is due to the increased capacity of the plasma proteins for binding thyroid hormones, rather than to any change in glandular function. In women taking oral contraceptives, the content of protein-bound iodine in blood serum should, therefore, not be used for the evaluation of thyroid function.

Oral contraceptives may accelerate erythrocyte sedimentation in the absence of any disease. This effect is due to a change in the proportion of the plasma protein fractions. Increases in plasma copper, iron and alkaline phosphatase have also been recorded.

Adverse reactions: During the first months of use of oral contraceptives, irregular bleeding may occur. Package quantities Pack of 22 tablets (one month's supply).

Further information Nil.

Product licence number 0065/5041.

MIXOGEN* INJECTION

Presentation 2 ml vials, for intramuscular injection. A clear oily solution, containing in each millilitre oestradiol benzoate 1 mg, oestradiol phenylpropionate 4 mg, testosterone propionate 20 mg, testosterone phenylpropionate 40 mg and testosterone isocaproate 40 mg.

Uses A combination of oestrogens and androgens which provides treatment for climacteric symptoms in women.

Dosage and administration Mixogen Injection should only be administered by deep injection into the gluteus maximus muscle.

Initially, 1 ml once every three weeks until symptoms are fully controlled, then 1 ml every four weeks.

Contra-indications, warnings, etc

Contra-indications:

- Thrombophlebitis, thrombo-embolic processes, or a history of these conditions.
- Known or suspected oestrogen-dependent tumours, e.g. mammary, genital carcinoma.
- Undiagnosed irregular vaginal bleeding.
- Acute or chronic liver disease or history of liver disease where the liver function tests have failed to return to normal. Jaundice or history of jaundice in pregnancy. Rotor syndrome or Dubin-Johnson syndrome.

N.B. The use of oestrogens is not contra-indicated in patients with a history of hepatitis whose liver functions are normal.

- Porphyria.
- Cerebrovascular or cardiovascular disease.
- Hyperlipoproteinaemia, especially in the presence of other risk factors which may indicate a predisposition to cerebrovascular or cardiovascular disorders.
- A history during pregnancy of severe pruritus, herpes gestationis or a deterioration of otosclerosis.
- Endometriosis.
- Pregnancy or suspected pregnancy.

Precautions and warnings: Pregnancy must be excluded before treatment is started. Whenever there is a reason to suspect pregnancy during treatment, this possibility must be investigated by the physician. If pregnancy has been confirmed the treatment must be discontinued immediately.

Physical examination should precede the prescribing of any oestrogen and should be repeated regularly. Special attention should be paid to duration of the cycle, body weight, blood pressure, heart, breasts, pelvic organs, legs and skin.

A cervical smear should be taken at regular intervals.

If any signs of thrombo-embolic processes occur, the use of the preparation must be discontinued immediately.

Oestrogen preparations may increase the risk of thrombosis and this should be taken into account when surgery is to be performed in patients using these preparations. Where possible, oestrogens should be discontinued approximately six weeks prior to elective surgery and not recommenced until the patient has recovered and is mobile.

Pre-existing uterine fibromyomata may increase in size under the influence of oestrogens, and if this is observed, administration of the preparation should be discontinued.

Since the glucose tolerance may diminish during the use of oestrogens, diabetic patients should be monitored closely.

Patients with myocardial or renal disease, varicose veins, epilepsy, migraine or asthma, require careful monitoring since sodium and water retention has been observed during continued use of oestrogens.

Since oestrogen preparations may cause an increase in blood pressure in predisposed patients, this should be checked regularly. In case of serious hypertension, further administration of the preparation must be withheld.

Patients wearing contact lenses should be advised that they may experience some discomfort.

If hypercalcaemia or hypercalciuria develop, treatment should be discontinued.

Administration to patients with nephrotic syndrome should be avoided.

Prolonged or excessive dosage of oestrogens inhibits pituitary function and on cessation of treatment, severe withdrawal bleeding may occur.

Interactions: Concurrent administration of liver enzyme inducing drugs such as rifampicin, barbiturates, phenylbutazone or phenytoin may decrease the effect of Mixogen.

Adverse reactions: There may be a risk of virilisation manifested by hoarseness of the voice, acne, hirsutism, enlarged clitoris and stimulation of libido. Hoarseness of the voice may be the first symptom of vocal change which may lead to an irreversible lowering of the voice. If signs of virilisation, particularly hoarseness of the voice, develop, treatment should be discontinued.

Other side-effects may be menstrual irregularities, nausea or vomiting, headache, sodium and water retention, breast tenderness, mood changes and uterine bleeding (during or on withdrawal of therapy).

Symptoms such as sudden severe headaches, pains in the chest, visual disturbances, or swelling of the arms or legs require immediate medical examination.

Pharmaceutical precautions Protect from light.

MIXOGEN* TABLETS

Presentation Round, white tablets, code-marked 'SZ7' on one side, with 'Organon' and a star on the reverse side.

Active ingredients: Ethinyloestradiol BP 0.0044 mg and Methyltestosterone BP 3.6 mg per tablet.

Uses A combination of oestrogen and androgen which provides treatment for climacteric symptoms in women.

Dosage and administration 1–2 tablets daily, more in severe cases, omitting treatment every fourth week. When symptoms are fully controlled, dosage may be gradually reduced to maintenance level.

Contra-indications, warnings, etc

Contra-indications:

- (a) Thrombophlebitis, thrombo-embolic processes, or a history of these conditions.
- (b) Known or suspected oestrogen-dependent tumours, e.g. mammary, genital carcinoma.
- (c) Undiagnosed irregular vaginal bleeding.
- (d) Acute or chronic liver disease or history of liver disease where the liver function tests have failed to return to normal. Jaundice or history of jaundice in pregnancy. Rotor syndrome or Dubin-Johnson syndrome.
- N.B.* The use of oestrogens is not contra-indicated in patients with a history of hepatitis whose liver functions are normal.
- (e) Porphyria.
- (f) Cerebrovascular or cardiovascular disease.
- (g) Hyperlipoproteinaemia, especially in the presence of other risk factors which may indicate a predisposition to cerebrovascular or cardiovascular disorders.
- (h) A history during pregnancy of severe pruritus, herpes gestationis or a deterioration of otosclerosis.
- (i) Endometriosis.
- (j) Pregnancy or suspected pregnancy.

Precautions and warnings: Pregnancy must be excluded before treatment is started. Whenever there is a reason to suspect pregnancy during treatment, this possibility must be investigated by the physician. If pregnancy has been confirmed, tablet-intake must be discontinued immediately.

Physical examination should precede the prescribing of any oestrogen and should be repeated regularly. Special attention should be paid to duration of the cycle, body weight, blood pressure, heart, breasts, pelvic organs, legs and skin.

A cervical smear should be taken at regular intervals.

If any signs of thrombo-embolic processes occur, the use of the preparation must be discontinued immediately.

Oestrogen preparations may increase the risk of thrombosis and this should be taken into account when surgery is to be performed in patients using these preparations. Where possible, oestrogens should be discontinued approximately six weeks prior to elective surgery and not recommenced until the patient has recovered and is mobile.

Pre-existing uterine fibromyomata may increase in size under the influence of oestrogens, and if this is observed, administration of the preparation should be discontinued.

Since the glucose tolerance may diminish during the use of oestrogens, diabetic patients should be monitored closely.

Patients with myocardial or renal disease, varicose veins, epilepsy, migraine or asthma, require careful monitoring since sodium and water retention has been observed during continued use of oestrogens.

Since oestrogen preparations may cause an increase in blood pressure in predisposed patients, this should be checked regularly. In case of serious hypertension, further administration of the preparation must be withheld.

Patients wearing contact lenses should be advised that they may experience some discomfort.

If hypercalcaemia or hypercalciuria develop, treatment should be discontinued.

Administration to patients with nephrotic syndrome should be avoided.

Tumours of the liver have been reported occasionally in patients subjected to prolonged treatment with C-17 α -alkylated androgenic-anabolic steroids. The possibility that these compounds may induce or enhance the development of hepatic tumours cannot at present be excluded and this should be considered when the use of this product is proposed, especially in young people who are not suffering from life-threatening disorders.

Prolonged or excessive dosage of oestrogens inhibits pituitary function and on cessation of treatment, severe withdrawal bleeding may occur.

Adverse reactions: There may be a risk of virilisation manifested by hoarseness of the voice, acne, hirsutism, enlarged clitoris and stimulation of libido. Hoarseness of the voice may be the first symptom of vocal change which may lead to an irreversible lowering of the voice. If signs of virilisation, particularly hoarseness of the voice, develop, treatment should be discontinued.

Other side-effects may be menstrual irregularities, nausea or vomiting, headache, sodium and water retention, breast tenderness, mood changes and uterine bleeding (during or on withdrawal of therapy).

Symptoms such as sudden severe headaches, pains in the chest, visual disturbances, or swelling of the arms or legs require immediate medical examination.

Interactions: Concurrent administration of liver enzyme inducing drugs such as rifampicin, barbiturates, phenylbutazone or phenytoin may decrease the effect of Mixogen.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Bottles of 100 tablets.

Further information Nil.

Product licence number 0065/5042.

MULTILOAD CU 250* ▼

Presentation The Multiload Cu 250 is an intrauterine device made of polyethylene, 3.6 cm in length with 27 cm of copper wire 0.3 mm diameter wrapped around the stem, giving a total surface area of 250 mm² of copper. The flexible side arms ensure that the Multiload Cu 250 remains in position as high as is possible against the fundus without the uterine cavity being stretched in any way. The device is preloaded on its inserter and a monofilament polypropylene thread is attached to the stem.

The Multiload Cu 250 can be regarded as a third generation IUD. As a result of its special shape the Multiload Cu 250 represents a breakaway from the principle that IUDs must be firmly embedded into the uterine cavity in order to prevent expulsion. In addition, with 250 mm² of copper wound around the vertical stem a very low pregnancy rate is obtained without using a maximum surface area.

As a result, the Multiload Cu 250 causes practically no cramp and no intermittent bleeding. Contractions of the uterus are cushioned by the wide upper end of the

Multiload Cu 250, resulting in flexure of the side arms which are designed to prevent expulsion.

The Multiload Cu 250 is suitable for both multiparous and nulliparous patients (however see Precautions and Warnings). The insertion procedure is simple and the device can be accurately positioned high up against the fundus. An expeller is not necessary.

Uses Intrauterine Contraception.

Dosage and administration It is recommended that the Multiload Cu 250 be replaced every three years.

Recommended procedure for inserting the Multiload Cu 250: Perform a bimanual examination of the uterus to determine its condition and position.

Expose the cervix with a bivalve speculum and hook a single tooth tenaculum to the posterior (sometimes anterior) lip of the cervix. A sufficiently good grip should be obtained with the tenaculum, without blocking the cervical canal, to align the uterine cavity with the canal. Cleanse the cervix with cotton wool soaked in antiseptic solution. Remove cellular debris from the external os of the cervix to prevent contamination of the uterine cavity. Lignocaine gel may be applied to produce local anaesthesia.

Sound the uterus to determine the depth and direction of the cavity. A good idea of the size and shape of the uterus is obtained by turning the sound carefully to and fro. If slight resistance is felt at the moment when the sound passes through the internal os it is advisable to dilate the cervical canal carefully with a No. 4 Hegar dilator.

The distance found between the external os and the fundus of the uterine cavity is set with a ring on the inserter; this ring is pre-set at 7 cm.

Introduce the Multiload Cu 250 with the inserter into the uterine cavity until it touches the fundus, bearing in mind the direction and depth determined with the sound. During this procedure it is desirable to pull the tenaculum in such a way that the axis of the cervical canal is stretched. Slight resistance may be encountered as the Multiload Cu 250 is pushed through the internal os uteri, particularly in nulliparous women, or women who have not had children for several years.

As soon as the Multiload Cu 250 and the inserter are resting against the fundus, the Multiload Cu 250 is removed from its housing by simply withdrawing the inserter while at the same time pulling the tenaculum in such a way that the axis of the cervical canal is stretched. It is important to ensure that the inserter is accurately removed in the correct direction, otherwise the Multiload Cu 250 may not be lodged as deeply as possible in the uterine cavity. Cut the thread of the Multiload Cu 250 to the required length.

Removal: The Multiload Cu 250 is usually removed after three years and replaced by a new one.

The ability to become pregnant is normally restored a short time after removal of the Multiload Cu 250.

In the case of pregnancy the Multiload Cu 250 must be removed upon diagnosis.

Removal procedure: Expose the cervix with a bivalve speculum. Grasp the thread of the Multiload Cu 250 firmly as near to the external os as possible. Pull it out carefully and steadily. There is a tendency for small quantities of calcium to form a sediment on the surface of all IUDs.

Contra-indications, warnings, etc

Contra-indications: Pregnancy, congenital or acquired

abnormalities of the uterine cavity, pelvic inflammatory disease either pre-existing or in a patient with a history of such conditions, acute cervicitis, acute or sub-acute salpingitis, endometritis or infected abortion in the past three months, dysfunctional uterine bleeding, cervical dysplasia, suspected or proven carcinoma of the cervix or endometrium, uterine polyps or fibroids, disturbance of the blood clotting mechanism and known allergy to copper.

Multiload Cu 250 should not be used with organic mercurial pessaries.

Precautions and warnings: When diathermy is used there is a possibility of heat injury to the endometrium in women with a copper IUD.

If pelvic infection occurs which is unresponsive to treatment, the Multiload Cu 250 should be removed. An association between the use of IUDs and pelvic infection has been reported. Appropriate antibiotic cover should be given three days prior to, and for at least ten days after insertion, in patients with a past history of rheumatic fever and certain known or suspected cardiac abnormalities, in order to preclude the possibility of precipitating sub-acute bacterial endocarditis.

The use of non-sterile techniques can result in sepsis. Spontaneous perforation is almost impossible; traumatic insertion procedures causing late perforation must be avoided. If a uterus is found to be less than 6 cm deep, insertion of a Multiload Cu 250 is not recommended.

Pain during and after insertion is more likely to occur in nulliparous than in multiparous women.

It has been demonstrated that the presence of an IUD in a pregnant uterus increases the risk of abortion and sepsis. Ectopic pregnancy may occur.

If in the unlikely event a patient presents with the Multiload Cu 250 in situ and she is pregnant, then as with all IUDs, the device must be removed.

The patient must be left in no doubt about the very slight chance of pregnancy and about the need to contact a doctor immediately if pregnancy should occur, as in this case the Multiload Cu 250 must be removed. After insertion the patient should be taught to examine herself to confirm the presence of the thread. It should also be pointed out to the patient that in the event of complications a doctor must always be consulted.

Some women are troubled by abdominal cramps after insertion. Post-insertion syncope may occur in some nulliparous patients. Intermittent bleeding or prolongation of menstruation may occur during the first two or three cycles.

Pharmaceutical precautions The Multiload Cu 250 is supplied sterile in a peel-open pouch, which should not be opened until required for insertion. Aseptic precautions should be carried out when handling the device. Care should be taken to ensure the sterile packages are not damaged; they should be stored in cool dry conditions.

Legal category POM.

Package quantities One outer package containing 10 Multiload Cu 250.

10 inner packs each containing 1 Multiload Cu 250 ready for immediate use and fitted with a disposable inserter.

Further information The amount of copper eluted from copper IUDs is well below the daily dietary intake of copper. No changes in blood levels of copper have been detected.

Product licence number 0065/0062.

OESTRADIOL* IMPLANTS

Presentation Pellets of fused, white crystalline hormone in several weights, for implantation.

Active ingredient: Oestradiol BPC 25 mg, 50 mg and 100 mg. The 25 mg weight has a diameter of 2.2 mm and the 50 mg and 100 mg a diameter of 4.5 mm.

Uses Implantation of fused implants of oestradiol provides a very slow release of the hormone. Approximate durations of effect are: 25 mg – 36 weeks. 50 mg – 44 weeks. 100 mg – 57 weeks. Indicated in females for long-term treatment in cases requiring oestrogen replacement, as in primary hypoplastic amenorrhoea, non-oestrogen-dependent mammary carcinoma (in women over 60), female castration and the climacteric.

In males, excessive libido and prostatic carcinoma.

Dosage and administration *Adults: Female:* Mammary carcinoma (in women over 60) 100–200 mg. Amenorrhoea (primary hypoplastic) 25 mg. Castration (with uterus) 25 mg. Castration (without uterus) 50 mg. Climacteric 25 mg.

Male: Prostatic carcinoma 100–300 mg; excessive libido 50 mg.

Frequency of replacement depends on the duration of activity of the implants administered.

Implants are inserted, either by means of a trocar and cannula or by open surgery, into an area where there is comparatively little movement, such as the lower abdominal wall or the buttock. Insertion is made under local anaesthetic and the wound is closed either with an adhesive dressing or a fine suture.

Oestradiol Implants are well tolerated but are so slowly absorbed that the endometrium is liable to progressive hypertrophy. For this reason, where the uterus is intact, Oestradiol Implants must invariably be placed superficially in case they have to be removed.

Whichever method is used for the insertion of implants, the following principles apply:

1. Full aseptic 'no touch' technique should be adopted.
2. Precautions should be taken to avoid the formation of haematoma at the site.
3. The rate of absorption of the active ingredient depends on the surface area of the implant. Thus the daily rate of absorption can be increased by supplying the total dose in a number of separate implants each sited on a separate track.

Contra-indications, warnings, etc

Contra-indications:

- (a) Thrombophlebitis, thrombo-embolic processes, or a history of these conditions.
 - (b) Known or suspected oestrogen-dependent tumours, e.g. mammary, genital carcinoma.
 - (c) Undiagnosed irregular vaginal bleeding.
 - (d) Acute or chronic liver disease or history of liver disease where the liver function tests have failed to return to normal. Jaundice or history of jaundice in pregnancy. Rotor syndrome or Dubin-Johnson syndrome.
- N.B.* The use of oestrogens is not contra-indicated in patients with a history of hepatitis whose liver functions are normal.
- (e) Porphyria.
 - (f) Cerebrovascular or cardiovascular disease.
 - (g) Hyperlipoproteinaemia, especially in the presence of other risk factors which may indicate a predis-

position to cerebrovascular or cardiovascular disorders.

- (h) A history during pregnancy of severe pruritus, herpes gestationis or a deterioration of otosclerosis.
- (i) Endometriosis.
- (j) Pregnancy or suspected pregnancy.

Precautions and warnings: Pregnancy must be excluded before treatment is started. Whenever there is a reason to suspect pregnancy during treatment, this possibility must be investigated by the physician. If pregnancy has been confirmed the implant must be removed immediately.

Physical examination should precede the prescribing of any oestrogen and should be repeated regularly. Special attention should be paid to duration of the cycle, body weight, blood pressure, heart, breasts, pelvic organs, legs and skin.

A cervical smear should be taken at regular intervals.

If any signs of thrombo-embolic processes occur, the implant must be removed immediately.

Oestrogen preparations may increase the risk of thrombosis and this should be taken into account when surgery is to be performed in patients using these preparations. Where possible, oestrogens should be discontinued approximately six weeks prior to elective surgery and not recommended until the patient has recovered and is mobile.

Pre-existing uterine fibromyomata may increase in size under the influence of oestrogens, and if this is observed the implant must be removed.

Since the glucose tolerance may diminish during the use of oestrogens, diabetic patients should be monitored closely.

Prolonged exposure to unopposed oestrogens may increase the risk of the development of endometrial carcinoma.

Patients with myocardial or renal disease, varicose veins, epilepsy, migraine or asthma, require careful monitoring since sodium and water retention has been observed during continued use of oestrogens.

Since oestrogen preparations may cause an increase in blood pressure in predisposed patients, this should be checked regularly. In case of serious hypertension, further administration of the preparation must be withheld.

Patients wearing contact lenses should be advised that they may experience some discomfort.

Hypercalcaemia or hypercalciuria may develop either spontaneously or as a result of hormonal therapy in patients with certain tumours, especially in mammary carcinoma, hypernephroma and bronchial carcinoma. If either hypercalcaemia or hypercalciuria develop during such treatment, the preparation should be removed and appropriate measures taken to normalise calcium levels.

Because oestrogens may accelerate epiphyseal closure, they should be used judiciously in those young patients in whom bone growth is not yet complete.

Prolonged or excessive dosage of oestrogens inhibits pituitary function and on cessation of treatment, severe withdrawal bleeding may occur.

Adverse reactions: Adverse reactions are rare and only appear if the dosage is too high or treatment is prolonged. These include nausea and vomiting, headache, sodium and water retention, breast tenderness and gynaecomastia (may occur in the treatment of prostatic carcinoma), menstrual disturbances, uterine bleeding (during or on withdrawal of therapy) and psychotic disturbances.

Symptoms such as sudden severe headaches, pains in

the chest, visual disturbances, swelling of the arms or legs require immediate medical examination.

In male patients reduced libido, impotence and disturbances of spermatogenesis may occur.

Interactions: Concurrent administration of liver enzyme inducing drugs such as rifampicin, barbiturates, phenylbutazone or phenytoin may decrease the effect of Oestradiol Implants.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Each sterile implant is supplied singly, in a sealed glass tube. Available in the following weights: 25 mg, 50 mg and 100 mg.

Further information Nil.

25 mg 0065/5074

50 mg 0065/5075

100 mg 0065/5076

ORABOLIN*

Presentation Round, flat white tablets, diameter 9 mm, code-marked 'SB3' on one side, with 'Organon' and star on the reverse side.

Active ingredient: Ethyloestrenol BP 2 mg per tablet.

Uses Ethyloestrenol is an orally active anabolic steroid.

Dosage and administration *Adults:* 1-2 tablets orally daily. Not recommended for children.

Contra-indications, warnings, etc

Contra-indications: Pregnancy, prostatic carcinoma, mammary carcinoma in the male and in severe disturbances of liver function.

Hypercalcaemia or hypercalciuria may develop either spontaneously or as a result of therapy in patients with certain tumours, especially in mammary carcinoma, hypernephroma and bronchial carcinoma. If hypercalcaemia or hypercalciuria develops during such treatment the preparation should be discontinued and appropriate measures should be taken to normalise calcium levels.

Treatment should be discontinued if cholestatic jaundice appears or liver function tests become abnormal.

Tumours of the liver have been reported occasionally in patients subjected to prolonged treatment with C-17 α alkylated androgenic-anabolic steroids. The possibility that these compounds may induce or enhance the development of hepatic tumours cannot at present be excluded and this should be considered when the use of this product is proposed, especially in young people who are not suffering from life-threatening disorders.

C-17 α -alkylated anabolic steroids have also been reported to increase the hypoprothrombinaemic action of oral anticoagulants. This should be taken into account when Orabolin is administered concomitantly with oral anticoagulants, in which case reduction of the anticoagulant dosage may be necessary.

Patients with myocardial or renal dysfunction, hypertension or epilepsy should be observed carefully, since anabolic steroids may cause sodium and water retention. The preparation should not be administered for periods longer than three months and the recommended dosage should not be exceeded.

Skeletal maturation should be followed carefully when treating young people, since anabolic steroids in high dosages may accelerate this process.

Precautions and warnings: Young women whose cycles are not yet stabilised may experience irregular cycle control in the initial stages of treatment.

In diabetics, the need for insulin or other anti-diabetic drugs may be reduced.

Adverse reactions: When administered in the recommended dosages and for short periods of time (up to four weeks) adverse reactions may occur very rarely. Occasionally after high dosages, some liver function tests have shown abnormal values. These deviations, however, were transient and completely reversible after discontinuation of treatment. In some cases, particularly those treated with high dosages, nausea and some sodium and water retention may occur.

The possibility of menstrual disturbances exists, probably resulting from an inhibition of the secretion of gonadotrophins from the pituitary and/or from the occurrence of a progestational effect. In such cases the treatment should be discontinued or the dosage decreased.

Interactions: Concurrent administration of liver enzyme inducing drugs such as rifampicin, barbiturates, phenylbutazone or phenytoin may decrease the effect of Orabolin.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Bottles of 100 tablets.

Further information Nil.

Product licence number 0065/5043.

ORADEXON-ORGANON* INJECTION

Presentation A clear aqueous solution for injection, available as 1 ml ampoules containing dexamethasone sodium phosphate 5 mg per ml and as 2 ml vials containing the equivalent of 4 mg dexamethasone per ml (5 mg/ml dexamethasone sodium phosphate is approximately equivalent to 4 mg/ml dexamethasone.)

Uses Dexamethasone has powerful anti-inflammatory effects, little mineralocorticoid activity, and it produces minimal fluid retention. Oradexon-Organon may be administered intravenously, intramuscularly or as a rectal drip. It is particularly useful for intravenous use in the treatment of all acute conditions in which corticosteroids may be life-saving. In addition, Oradexon-Organon has a wide range of uses by local injection in physical medicine, for the treatment of such conditions as rheumatoid arthritis, osteoarthritis, supraspinatus tendinitis, Dupuytren's contracture, humeral epicondylitis and for local treatment of ulcerative colitis by rectal drip. Oradexon-Organon injection is also of value in the control of cerebral oedema caused by neoplasms, injuries, surgery, or cerebrovascular accidents.

Dosage and administration All dosages indicated relate to dexamethasone.

Rapid intravenous injection of massive doses of corticosteroids may sometimes cause cardiovascular collapse; the injection should therefore be given over a period of not less than 10 minutes.

Suggested dosages for adults: *Intravenous injection or infusion:* In acute conditions endangering life, such as shock (haemorrhagic, bacteraemic, traumatic, cardiogenic, surgical, snake venom, shock from burns). In severe allergic reactions (drug hypersensitivity, anaphy-

laxis, status asthmaticus), in fulminating infections (peritonitis, pneumonia, meningitis, septicaemia) in hepatic coma, cerebral oedema: 8 to 40 mg, either as a slow intravenous injection or as an infusion in glucose, saline or Ringer's solution. Dosage should be adjusted according to the severity of the condition and the patient's response.

Injection into joints, bursae, tendon sheaths and local infiltration: In chronic conditions (rheumatoid arthritis, osteoarthritis, supraspinatus tendinitis, Dupuytren's contracture, humeral epicondylitis); intra-articular (large joints) 4 mg; intra-bursal 2 mg; tendon sheaths 2 mg; local infiltration 2 mg. Administration by these routes calls for strict asepsis.

Rectal Drip: In cases of ulcerative colitis, Oradexon-Organon may be administered in a dose of 4 mg diluted in 120 ml saline.

Suggested dosages for children: Dosage requirements are variable and may have to be changed according to individual needs. Usually 0.25 mg/kg to 0.50 mg/kg of body weight daily.

Contra-indications, warnings, etc

Contra-indications: Systemic corticosteroids are generally contraindicated in patients with Cushing's Syndrome, gastro-intestinal ulcers, systemic fungal infections or acute bacterial or viral infections, particularly ocular herpes infections, active tuberculosis and acute psychosis.

Local injection of a corticosteroid is contra-indicated in the presence of an infection at the injection site (e.g. infectious arthritides, resulting from gonorrhoea or tuberculosis).

When pregnancy is present or suspected, the benefits of the use of corticosteroids should be weighed against the possible hazards to the foetus.

While on corticosteroid therapy, patients should not be vaccinated against smallpox. Other immunisation procedures should be undertaken under close observation as corticosteroid therapy may interfere with active immunisation due to the immuno-suppressive effects of corticosteroids.

No contra-indications exist when corticosteroids, in a large single dose, are used in conditions where life is endangered.

Precautions and warnings:

1. Patients currently on corticosteroid therapy or those who have been on such treatment within the previous year may require special control measures if involved in anaesthesia, surgical procedures and other stress. These special control measures usually involve increased dosage of rapidly acting corticosteroids and are indicated before, during, and after the stressful situation.

2. Withdrawal of corticosteroids should always be gradual and related to the duration of use and should be carried out under strict medical supervision. Withdrawal may result in acute rebound exacerbation of disease, acute adrenocortical insufficiency, polyarteritis.

3. The use of corticosteroids in the presence of other disorders (e.g. diabetes mellitus, tuberculosis, amoebiasis, osteoporosis, a history of mental disorders, cardiomyopathy, hypertension and renal insufficiency) or of drugs with specific actions (e.g. hypoglycaemics), impinging on the effects of corticosteroids may result in imbalance of control.

4. Corticosteroid administration will result in certain effects, the severity, significance and extent of which

vary with the dosage and duration of treatment and the particular corticosteroid used. These include disturbance in electrolyte balance, mineral metabolism, glucose metabolism and gluconeogenesis, nitrogen depletion, diminished lymphoid tissue and immune response, inhibition of pituitary function, Cushingoid Syndrome, increase in blood coagulability, diminished inflammatory response.

5. Growth and development of children on prolonged corticosteroid therapy should be carefully observed (see 'adverse reactions').

6. Corticosteroid therapy is non-specific, suppresses the symptoms and signs of disease and enhances susceptibility to infections; appropriate antimicrobial therapy should accompany corticosteroid therapy when necessary.

Corticosteroids appear in breast milk in very small quantities. Mothers taking high doses of corticosteroids should be advised not to breast feed.

When injecting into joints or bursae appropriate examination of the fluid is necessary to exclude a septic process. If septic arthritis occurs, appropriate antimicrobial therapy should be instituted. Corticosteroids should not be injected into unstable joints. Intra-articular injections of a corticosteroid may produce systemic as well as local effects.

Cases of ruptured tendon have been reported following the injection of corticosteroids directly into a tendon. In the treatment of conditions such as tendinitis or tenosynovitis care should be taken to inject into the space between the tendon sheath and the tendon.

Interactions: Concomitant use of corticosteroids and diuretics may result in an enhanced potassium loss.

Concurrent administration of liver enzyme inducing drugs such as rifampicin, ephedrine, barbiturates, phenylbutazone or phenytoin may decrease corticosteroid effects, while if anticoagulants are given with the corticosteroid, adjustment of dosage of the former is usually necessary.

Salicylates should be used cautiously in conjunction with corticosteroids in hypoprothrombinaemia.

If patients undergoing long term therapy with corticosteroids are concomitantly given salicylates, any reduction in corticosteroid dosage should be made with caution, since cases of salicylate intoxication under these conditions have been reported.

Adverse reactions: Adverse reactions associated with short-term corticosteroid therapy in high doses are uncommon.

The major adverse reactions with prolonged corticosteroid therapy are: peptic ulcers, acute pancreatitis, hypokalaemia, infections, suppression of growth in children, CNS effects (ranging from euphoria to frank psychotic manifestations), suppression of ACTH secretion and decreased reactive ability of the adrenal cortex, osteoporosis, ocular effects, negative nitrogen and calcium balance, atrophy of the skin, impaired wound healing, myopathy, diabetogenic effect, sodium and water retention (oedema), hypertension, and development of a Cushingoid state (e.g. 'moon-face', striae, 'central obesity', 'buffalo hump', supraclavicular fat pads, acne, hirsutism).

Pseudotumor cerebri (benign increased intracranial pressure) has been reported in some children receiving systemically administered corticosteroids for prolonged periods; vomiting and papilloedema tend to subside with reduction of dosage.

Anaphylactic reactions, such as urticaria and bron-

chospasm, have occurred, although very rarely, after intravenous administration of corticosteroids, particularly in patients with a history of hypersensitivity to drugs or allergy to food. If such anaphylactic reactions occur, the following measures are advisable; immediate intravenous injection of adrenaline (0.1–0.5 mg dependent on bodyweight), intermittent positive-pressure ventilation and administration of aminophylline.

Local injection adverse reactions include post-injection flare and a painless destruction of the joint reminiscent of Charcot's arthropathy, especially with repeated intra-articular injections.

When large doses are given intravenously, a transitory burning or tingling sensation, mainly in the perineal area, is often experienced.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities 2 ml vials, singly containing 4 mg per ml dexamethasone, 1 ml ampoules in boxes of 25, containing 5 mg per ml dexamethasone sodium phosphate.

Further information Oradexon-Organon Injection is an important drug in the management of cerebral oedema which accompanies many intracranial conditions, e.g. neoplasms, trauma, thrombotic episodes, post-radiotherapy or post-surgery. The reduction in intracranial pressure which can be achieved by its usage relieves many of the unpleasant symptoms associated with this condition, enables early neurological investigative measures to be instigated and neurological procedures to be carried out.

Compatibility with infusion fluids: Oradexon-Organon Injection is compatible with the following i.v. fluids:

Dextrose 2.5% to 10% in water or normal saline or half-strength saline, invert sugar 5% or 10% in water or saline, lactated Ringer's injection, Ringer's injection, sodium chloride injection, sodium lactate (1/6M) injection.

Product licence number 0065/5013.

ORADEXON – ORGANON* TABLETS

Presentation Tablets of Dexamethasone BP. Round, flat, white tablets: 0.5 mg strength code-marked 'XC4', and 2 mg strength 'XC8', with 'Organon' and a star on reverse side.

Active ingredient: Dexamethasone BP 0.5 mg and 2 mg.

Uses Dexamethasone has powerful anti-inflammatory and anti-allergic properties and is indicated in a wide variety of disorders amenable to glucocorticoid therapy, as well as in the control of cerebral oedema. Dexamethasone has little mineralocorticoid activity and therefore has little influence on electrolyte metabolism. It is consequently not indicated in adrenal replacement therapy.

Dosage and administration *Adults:* In acute and chronic conditions 4 mg daily or more may initially be given if necessary; the dose is reduced to the minimum sufficient to control symptoms and signs of disease. Before terminating treatment the daily dose should be gradually reduced. A daily maintenance dose of 0.5–1.5 mg should be sufficient in most chronic diseases. In cerebral oedema daily doses of the order of 6–8 mg are usually appropriate.

Children: The usual daily dose is in the range of 0.01–0.04 mg/kg body weight.

Dosage of corticosteroids should be adjusted on the basis of the individual patient response.

Contra-indications, warnings, etc

Contra-indications: Systemic corticosteroids are generally contra-indicated in patients with Cushing's Syndrome, gastro-intestinal ulcers, systemic fungal infections or acute bacterial or viral infections, particularly ocular herpes infections, active tuberculosis and acute psychosis.

When pregnancy is present or suspected, the benefits of the use of corticosteroids should be weighed against the possible hazards to the foetus.

While on corticosteroid therapy, patients should not be vaccinated against smallpox. Other immunisation procedures should be undertaken under close observation as corticosteroid therapy may interfere with active immunisation due to the immuno-suppressive effects of corticosteroids.

Precautions and warnings:

Patients currently on corticosteroid therapy or those who have been on such treatment within the previous year may require special control measures if involved in anaesthesia, surgical procedures and other stress. These special control measures usually involve increased dosage of rapidly-acting corticosteroids and are indicated before, during and after the stressful situation.

Withdrawal of corticosteroids should always be gradual and related to the duration of use and should be carried out under strict medical supervision. Withdrawal may result in acute rebound exacerbation of disease, acute adrenocortical insufficiency, polyarteritis.

The use of corticosteroids in the presence of other disorders (e.g. diabetes mellitus, tuberculosis, amoebiasis, osteoporosis, a history of mental disorders, cardiomyopathy, hypertension, and renal insufficiency) or of drugs with specific actions (e.g. hypoglycaemics), impinging on the effects of corticosteroids may result in imbalance of control.

Corticosteroid administration will result in certain effects, the severity, significance and extent of which, vary with the dosage and duration of treatment and the particular corticosteroid used. These include disturbance in electrolyte balance, mineral metabolism, glucose metabolism and gluconeogenesis, nitrogen depletion, diminished lymphoid tissue and immune response, inhibition of pituitary function, Cushingoid Syndrome, increase in blood coagulability, diminished inflammatory response.

Growth and development of children on prolonged corticosteroid therapy should be carefully observed (see 'adverse reactions').

Corticosteroid therapy is non-specific, suppresses the symptoms and signs of disease, and enhances susceptibility to infections; appropriate antimicrobial therapy should accompany corticosteroid therapy when necessary.

Corticosteroids appear in breast milk in very small quantities. Mothers taking high doses of corticosteroids should be advised not to breast feed.

Interactions: Concomitant use of corticosteroids and diuretics may result in an enhanced potassium loss.

Concurrent administration of liver enzyme inducing drugs such as rifampicin,ephedrine, barbiturates, phenylbutazone or phenytoin may decrease corticosteroid effects, while if anticoagulants are given with the

corticosteroid, adjustment of dosage of the former is usually necessary.

Salicylates should be used cautiously in conjunction with corticosteroids in hypoprothrombinaemia.

If patients undergoing long term therapy with corticosteroids are concomitantly given salicylates, any reduction in corticosteroid dosage should be made with caution, since cases of salicylate intoxication under these conditions have been reported.

Antacids, especially those containing magnesium trisilicate, have been reported to impair the gastrointestinal absorption of corticosteroids. Therefore doses of one agent should be spaced as far as possible from the other.

Adverse reactions: Adverse reactions associated with short-term corticosteroid therapy in high doses are uncommon.

The major adverse reactions with prolonged corticosteroid therapy are: peptic ulcers, acute pancreatitis, hypokalaemia, suppression of growth in children, CNS effects (ranging from euphoria to frank psychotic manifestations), suppression of ACTH secretion and decreased reactive ability of the adrenal cortex, osteoporosis, ocular effects, negative nitrogen and calcium balance, atrophy of the skin, impaired wound healing, myopathy, diabetogenic effect, sodium and water retention (oedema), hypertension, and development of a Cushingoid state (e.g. 'moon-face', striae, 'central obesity', 'buffalo hump', supraclavicular fat pads, acne, hirsutism).

Pseudotumor cerebri (benign increased intracranial pressure) has been reported in some children receiving systemically administered corticosteroids for prolonged periods; vomiting and papilloedema tend to subside with reduction of dosage.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities *Oradexon-Organon 0.5 mg tablets:* Bottles of 500.

Oradexon-Organon 2 mg tablets: Bottles of 100 and 500.

Further information As Oradexon-Organon (dexamethasone) has little mineralocorticoid activity and there is minimal fluid retention, it is particularly suitable where increased blood pressure is to be avoided.

2 mg 0065/5045

OVESTIN*

Presentation Round, flat, white tablets, diameter 8 mm, code-marked 'DG4' on one side, with 'Organon' and star on the reverse.

Active ingredient: Oestriol 0.25 mg per tablet.

Uses Oestriol is a naturally-occurring oestrogen with a selective action on the cervix and vagina; unlike most other oestrogenic hormones, oestriol has in therapeutic dosages relatively little proliferative effect on the endometrium, so that uterine bleedings occur only rarely.

Ovestin tablets are mainly indicated for the treatment of vaginal and cervical disorders and, in higher dosages, also for the treatment of symptoms of oestrogen deficiency, where they occur before or after the menopause.

Dosage and administration Initially 1 or 2 tablets, reducing to 1 tablet daily.

Contra-indications, warnings, etc

Contra-indications: Thrombophlebitis, thrombo-embolic processes, or a history of these conditions.

Known or suspected oestrogen-dependent tumours, e.g. mammary, genital carcinoma.

Undiagnosed irregular vaginal bleeding.

Acute or chronic liver disease or history of liver disease where the liver function tests have failed to return to normal. Jaundice or history of jaundice in pregnancy. Rotor syndrome or Dubin-Johnson syndrome.

N.B. The use of oestrogens is not contra-indicated in patients with a history of hepatitis whose liver functions are normal.

Porphyria.

Cerebrovascular or cardiovascular disease.

Hyperlipoproteinaemia, especially in the presence of other risk factors which may indicate a predisposition to cerebrovascular or cardiovascular disorders.

A history during pregnancy of severe pruritus, herpes gestationis or a deterioration or otosclerosis.

Endometriosis.

Pregnancy or suspected pregnancy.

Precautions and warnings: Pregnancy must be excluded before treatment is started. Whenever there is a reason to suspect pregnancy during treatment, this possibility must be investigated by the physician. If pregnancy has been confirmed, tablet-intake must be discontinued immediately.

Physical examination should precede the prescribing of any oestrogen and should be repeated regularly. Special attention should be paid to duration of the cycle, body weight, blood pressure, heart, breasts, pelvic organs, legs and skin.

A cervical smear should be taken at regular intervals.

If any signs of thrombo-embolic processes occur, treatment should be discontinued immediately.

Oestrogen preparations may increase the risk of thrombosis and this should be taken into account when surgery is to be performed in patients using these preparations. Where possible, oestrogens should be discontinued approximately six weeks prior to elective surgery and not recommenced until the patient has recovered and is mobile.

Pre-existing uterine fibromyomata may increase in size under the influence of oestrogens, and if this is observed administration of the preparation should be discontinued.

Since the glucose tolerance may diminish during the use of oestrogens, diabetic patients should be monitored closely.

Prolonged exposure to unopposed oestrogens may increase the risk of the development of endometrial carcinoma.

Patients with myocardial or renal disease, varicose veins, epilepsy, migraine or asthma, require careful monitoring since sodium and water retention has been observed during continued use of oestrogens.

Since oestrogen preparations may cause an increase in blood pressure in predisposed patients, this should be checked regularly. In case of serious hypertension, further administration of the preparation must be withheld.

Patients wearing contact lenses should be advised that they may experience some discomfort.

Because oestrogens may accelerate epiphyseal closure, they should be used judiciously in those young patients in whom bone growth is not yet complete.

Prolonged or excessive dosage of oestrogens inhibits pituitary function and on cessation of treatment, severe withdrawal bleeding may occur.

Adverse reactions: Adverse reactions are rare and only appear if the dosage is too high or treatment is prolonged. These include nausea and vomiting, headache, sodium and water retention, breast tenderness, menstrual disturbances, uterine bleeding (during or on withdrawal of therapy) and psychotic disturbances.

Symptoms such as sudden severe headaches, pains in the chest, visual disturbances, or swelling of the arms or legs require immediate medical examination.

Interactions: Concurrent administration of liver enzyme inducing drugs such as rifampicin, barbiturates, phenylbutazone or phenytoin may decrease the effect of Ovestin.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Bottles of 100 tablets.

Further information Nil.

Product licence number 0065/5049.

PREGNYL*

Presentation Pregnyl contains purified chorionic gonadotrophin prepared from the urine of pregnant women. Ampoules containing a white, freeze-dried plug, with 1 ml ampoules of solvent.

Active ingredient: Chorionic Gonadotrophin BP 500 i.u., 1,500 i.u. or 5,000 i.u. After addition of the solvent to the freeze dried substance, the solution should be used immediately.

Uses Chorionic gonadotrophin has physiological activity similar to that of the luteinising hormone of the anterior pituitary gland. It induces ovulation in the FSH-primed ovary, and facilitates corpus luteum formation; in the male, it stimulates the interstitial tissue of the testes to produce testosterone. The action of Pregnyl is identical with the stimulus which determines prenatal descent of the testes; when underdevelopment is associated with undescended testes, Pregnyl accelerates growth and development. Indicated in the female for anovulatory sterility and secondary amenorrhoea; in males, for undescended testes, ectopic testes requiring operation and delayed pubertal growth.

Dosage and administration *Adults: Anovulatory sterility:* 500 i.u. Serum Gonadotrophin BP intramuscularly daily from fifth to fourteenth day of cycle, followed by 5,000 i.u. Pregnyl intramuscularly daily from fifteenth to twenty-fourth day of cycle. If there is no response to the first course of injections, after one month a further course should be given with doubled dosage.

Secondary amenorrhoea: 3,000 i.u. Serum Gonadotrophin BP intramuscularly daily for five days, followed by three injections of 1,500 i.u. Pregnyl intramuscularly on alternate days. This course of treatment should be repeated for two or three cycles; menstruation will normally occur 8 to 12 days after the last injection in each course of treatment.

Undescended testes (in males over 17 years of age): 1,000 i.u. intramuscularly twice weekly; treatment should be continued for one or two months after testicular descent.

Ectopic testes requiring operation: Pre-medication with Pregnyl for one or two months before surgery ensures optimal blood supply and elasticity: 500 i.u. intramuscularly two or three times weekly.

Children: Undescended testes: 500 i.u. intramuscularly three times weekly; Pregnyl treatment should be continued for one or two months after testicular descent.

Delayed pubertal growth: 500 i.u. intramuscularly twice weekly for four to six weeks; if necessary, the course of treatment may be repeated later.

Contra-indications, warnings, etc

Contra-indications: Known or suspected androgen-dependent tumours, carcinoma of the prostate or mammary carcinoma in males.

Precautions and warnings: Evidence of sexual precocity is an indication for the immediate withdrawal of treatment. However after regression of undue development, therapy on a reduced dosage regime may be resumed in those cases in which continuation of therapy is necessary.

Patients with myocardial or renal dysfunction, epilepsy or migraine require careful monitoring, since fluid retention has been observed after administration of high dosages of HCG.

When treating anovulatory infertility by administration of an FSH-preparation followed by HCG, the stimulation of the ovaries by the FSH-preparation may give rise to excessive oestrogen levels. In such cases HCG should not be administered, since there is a risk of inducing multiple pregnancy or the ovarian hyperstimulation syndrome.

If pregnancy follows treatment with FSH and HCG preparations, the possibility of a multiple pregnancy is greater than normal.

Patients with a known allergic diathesis should be given an intradermal skin test prior to commencement of treatment with Pregnyl.

Adverse reactions: Administration of high HCG dosages may occasionally lead to development of oedema in males; this is usually regarded as a manifestation of sodium and water retention attributable to androgen secretion resulting from stimulation of the Leydig cells. Dosage should be considerably reduced in such cases.

Pharmaceutical precautions Protect from the light and store at a temperature not exceeding 20°C. In the dry state, in sealed containers, Pregnyl will retain its full activity for three years from the date of manufacture. Solutions are unstable and should be used freshly prepared.

Legal category POM.

Package quantities Boxes containing 12 ampoules of freeze-dried Chorionic Gonadotrophin BP 500 i.u., 1,500 i.u. or 5,000 i.u., with twin 1 ml ampoules of solvent.

Further information It is generally considered that active intervention should be instituted if a testis has not descended by the age of six years. If descent is not accomplished by using chorionic gonadotrophin, surgery is indicated. Prior use of chorionic gonadotrophin may, however, increase vascularity and reduce tissue friability of the surgical field.

SUSTANON '100'

Presentation A clear, oily solution in 1 ml ampoules, each containing:

Testosterone Propionate BP	20 mg
Testosterone Phenylpropionate BP	40 mg
Testosterone Isocaproate	40 mg

Uses Sustanon is a combination of testosterone esters for intramuscular injection, with an extended duration of action. Indicated, in the male, for the treatment of the climacteric, delayed puberty, eunuchism, eunuchoidism, hypogonadism and impotence due to testicular insufficiency. Sustanon is also indicated in certain inoperable mammary carcinomas in the female.

Dosage and administration Sustanon '100' should only be administered by deep injection into the gluteus maximus muscle.

Adults: Generally, 1 ml Sustanon '100' every two weeks. In some conditions, e.g. mammary carcinoma, higher doses or increased frequency of injection may be necessary.

Contra-indications, warnings, etc

Contra-indications: Contraindicated in pregnancy and in cases of mammary or prostatic carcinoma in males.

Precautions and warnings: Hypercalcaemia or hypercalciuria may develop either spontaneously or as a result of hormonal therapy in patients with certain tumours especially mammary carcinoma, hypernephroma and bronchial carcinoma. If hypercalcaemia or hypercalciuria develop during such treatment the preparation should be discontinued and appropriate measures taken to normalise calcium levels.

Androgens should be used with great caution in patients with myocardial, renal or hepatic dysfunction, epilepsy, migraine or hypertension, since sodium and water retention may occur.

In treating males, stimulation to the point of increasing nervous, mental and physical activities beyond the patient's cardiovascular capacities should be avoided. If priapism or other signs of excessive sexual stimulation develop, therapy should be discontinued.

Androgens may reduce thyroxine-binding globulin and PBI levels without inducing clinical hypothyroidism; the significance of this is unknown.

Administration to patients with nephrotic syndrome should be avoided.

Androgens should be used cautiously in young boys to avoid possible premature epiphyseal closure or precocious sexual development.

Androgen therapy should only be used in male hypogonadism in which testosterone levels have been demonstrated to be low.

Adverse reactions: Sustanon '100', like any other androgen therapy, may give rise to the following adverse reactions:

- priapism and other signs of excessive sexual stimulation.
- phallic enlargement and increased frequency of erection in pre-pubertal males.
- sodium and water retention after prolonged administration of very high dosages.
- oligospermia and a decreased ejaculatory volume after prolonged administration of very high dosages.
- virilisation (e.g. hoarseness of the voice, acne, hirsutism) enlarged clitoris and stimulation of libido.
- menstrual irregularities in female patients.

Treatment should be interrupted until these symptoms have disappeared, after which it should be continued at a lower dosage.

Hoarseness of the voice may be the first symptom of vocal change which may lead to irreversible lowering of the voice. If signs of virilisation, particularly lowering of the voice, develop, treatment should be discontinued.

Interactions: Concurrent administration of liver enzyme inducing drugs such as rifampicin, barbiturates, phenylbutazone or phenytoin may decrease the effect of Sustanon '100'.

Pharmaceutical precautions Protect from light. Store at room temperature (15° to 25°C). After storage at lower temperatures precipitation of the arachis oil vehicle may occur. By heating the ampoules at 100°C for a few minutes or at 40°C for one hour the solution will become clear. The precipitation and rewarming does not affect the activity of the injection.

Legal category POM.

Package quantities 1 ml ampoules in boxes of 3.

Further information Sustanon is the ideal parenteral preparation for long-term androgen therapy; no single testosterone ester can provide the same sustained level of androgenic activity and rapid onset of action. The prolonged activity is such that only an occasional injection is needed to maintain the required therapeutic level.

Product licence number 0065/5019.

SUSTANON '250'

Presentation A clear, oily solution in 1 ml ampoules each containing:

Testosterone Propionate BP	30 mg
Testosterone Phenylpropionate BP	60 mg
Testosterone Isocaproate	60 mg
Testosterone Decanoate	100 mg

Uses Sustanon is a combination of testosterone esters for intramuscular injection, with an extended duration of action. Indicated, in the male, for the treatment of the climacteric, delayed puberty, eunuchism, eunuchoidism, hypogonadism, and impotence due to testicular insufficiency. Sustanon is also indicated in certain inoperable mammary carcinomas in the female.

Dosage and administration Sustanon 250 should only be administered by deep injection into the gluteus maximus muscle.

Adults: Generally, 1 ml Sustanon 250 every four weeks. In some conditions, e.g. mammary carcinoma, higher doses or increased frequency of injection may be necessary.

Contra-indications, warnings, etc

Contra-indications: Contraindicated in pregnancy and in cases of mammary or prostatic carcinoma in males.

Precautions and warnings: Hypercalcaemia or hypercalciuria may develop either spontaneously or as a result of hormonal therapy in patients with certain tumours, especially in mammary carcinoma, hypernephroma and bronchial carcinoma. If hypercalcaemia or hypercalciuria develop during such treatment, the preparation should be discontinued and appropriate measures taken to normalise calcium levels.

Androgens should be used with great caution in patients with myocardial, renal or hepatic dysfunction, epilepsy, migraine or hypertension, since sodium and water retention may occur.

In treating males, stimulation to the point of increasing nervous, mental and physical activities beyond the patient's cardiovascular capacities should be avoided. If priapism or other signs of excessive sexual stimulation develop, therapy should be discontinued.

Androgens may reduce thyroxine-binding globulin and PBI levels without inducing clinical hypothyroidism; the significance of this is unknown.

Administration to patients with nephrotic syndrome should be avoided.

Androgens should be used cautiously in young boys to avoid possible premature epiphyseal closure or precocious sexual development.

Androgen therapy should only be used in male hypogonadism in which testosterone levels have been demonstrated to be low.

Adverse reactions: Sustanon 250, like any other androgen therapy, may give rise to the following adverse reactions.

- Priapism and other signs of excessive sexual stimulation.
- phallic enlargement and increased frequency of erections in prepubertal males.
- sodium and water retention after prolonged administration of very high dosages.
- oligospermia and a decreased ejaculatory volume after prolonged administration of very high dosages.
- virilisation (e.g. hoarseness of the voice, acne, hirsutism) enlarged clitoris and stimulation of libido.
- menstrual irregularities in female patients.

Treatment should be interrupted until these symptoms have disappeared, after which it should be continued at a lower dosage.

Hoarseness of the voice may be the first symptom of vocal change which may lead to irreversible lowering of the voice. If signs of virilisation, particularly lowering of the voice, develop, treatment should be discontinued.

Interactions: Concurrent administration of liver enzyme inducing drugs such as rifampicin, barbiturates, phenylbutazone or phenytoin may decrease the effect of Sustanon 250.

Pharmaceutical precautions Protect from light. Store at room temperature (15° to 25°C). After storage at lower temperatures precipitation of the arachis oil vehicle may occur. By heating the ampoules at 100°C for a few minutes or at 40°C for one hour the solution will become clear. The precipitation and rewarming does not affect the activity of the injection.

Legal category POM.

Package quantities 1 ml ampoules in boxes of 3.

Further information Sustanon is the ideal parenteral preparation for long-term androgen therapy; no single testosterone ester can provide the same sustained level of androgenic activity and rapid onset of action. The prolonged activity is such that only an occasional injection is needed to maintain the required therapeutic level.

Product licence number 0065/5086.

TESTORAL SUBLINGS*

Presentation Testosterone BP sublingual tablets Round, bi-convex, white to creamy-white tablets, diameter 8 mm, code-marked with a 'T' surrounded by 'Subling' on one side, with 'Organon' and a star on the reverse side.

Active ingredient: Testosterone BP 10 mg per tablet.

Uses The male hormone, testosterone, although inactivated when swallowed, can be absorbed directly through the buccal mucosa. Sublings should be placed under the tongue or between cheek and gum. Indicated for androgen replacement therapy.

Dosage and administration For androgen replacement therapy, 1-3 Sublings daily, reducing to 1 daily for as long as necessary.

Contra-indications, warnings, etc

Contra-indications: Mammary or prostatic carcinoma in males.

Precautions and warnings: Testosterone should be used with great caution in patients with myocardial, renal or hepatic dysfunction, epilepsy, migraine or hypertension since androgens may cause sodium and water retention.

Stimulation to the point of increasing nervous, mental and physical activities beyond the patient's cardiovascular capacities should be avoided. If priapism or other signs of excessive sexual stimulation develop, therapy should be discontinued.

Androgens may reduce thyroxine-binding globulin and PBI levels without inducing clinical hypothyroidism; the significance of this is unknown.

If hypercalcaemia or hypercalciuria develop, treatment should be discontinued.

Administration to patients with nephrotic syndrome should be avoided.

Androgens should be used cautiously in young boys to avoid possible premature epiphyseal closure or precocious sexual development.

Androgen therapy should only be used in male hypogonadism in which testosterone levels have been demonstrated to be low.

Adverse reactions: Testoral Sublings, like any other androgen therapy, may give rise to the following adverse reactions:

- priapism and other signs of excessive sexual stimulation.
- phallic enlargement and increased frequency of erections in prepubertal males.
- sodium and water retention after prolonged administration of very high dosages.
- oligospermia and a decreased ejaculatory volume after prolonged administration of very high dosages.

Treatment should be interrupted until these symptoms have disappeared, after which it should be continued at a lower dosage.

Hoarseness of the voice may be the first symptom of vocal change which may lead to irreversible lowering of the voice. If signs of virilisation, particularly lowering of the voice, develop, treatment should be discontinued.

Interactions: Concurrent administration of liver enzyme inducing drugs such as rifampicin, barbiturates, phenylbutazone or phenytoin may decrease the effect of Testoral Sublings.

Overdosage: Treatment of overdosage is by gastric lavage with appropriate supportive therapy.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Bottles of 100 tablets.

Further information Sublings provide testosterone in smooth-texture tablets, specially prepared for sublingual absorption.

Product licence number 0065/5051.

TESTOSTERONE IMPLANTS

Presentation Pellets of fused, crystalline hormone for implantation.

Active ingredient: Testosterone BP 100 mg or 200 mg, each with a diameter of 4.5 mm.

Uses Implantation of fused implants of testosterone provides slow release of the hormone; approximate duration of effect: 100 mg – 30 weeks; 200 mg – 34 weeks. Indicated for conditions requiring maintenance therapy with androgens, i.e. in the male, castration, climacteric, eunuchoidism, deficient libido, hypogonadism: in the female, deficient libido, mammary fibroadenosis and mammary carcinoma.

Dosage and administration *Adults: Male:* 200–600 mg depending on individual requirements.

Female: Deficient libido, 100 mg; mammary fibroadenosis, 100 mg or 200 mg; mammary carcinoma, 500 – 1,500 mg.

Implants are inserted, either by means of a trocar and cannula or by open surgery, into an area where there is comparatively little movement, such as the lower abdominal wall or the buttock. Insertion is made under local anaesthetic and the wound is closed either with an adhesive dressing or a fine suture.

Whichever method is used for the insertion of implants, the following principles apply:

1. Full aseptic 'no touch' technique should be adopted.
2. Precautions should be taken to avoid the formation of haematoma at the site.
3. The rate of absorption of the active ingredient depends on the surface area of the implant. Thus the daily rate of absorption can be increased by supplying the total dosage in a number of separate implants each sited on a separate track.

Frequency of replacement depends on the duration of activity of the implants administered.

Contra-indications, warnings, etc

Contra-indications: Contra-indicated in pregnancy, and in cases of mammary or prostatic carcinoma in males.

Precautions and warnings: Hypercalcaemia or hypercalciuria may develop either spontaneously or as a result of hormonal therapy in patients with certain tumours especially in mammary carcinoma, hypernephroma and bronchial carcinoma. If hypercalcaemia or hypercalciuria develop during such treatment the preparation should be discontinued and appropriate measures should be taken to normalise calcium levels.

Androgens should be used with great caution in patients with myocardial, renal or hepatic dysfunction, epilepsy, migraine or hypertension, since sodium and water retention may occur.

Stimulation to the point of increasing nervous, mental and physical activities beyond the patient's cardio-

vascular capacities should be avoided. If priapism or other signs of excessive sexual stimulation develop, therapy should be discontinued.

Androgens may reduce thyroxine-binding globulin and PBI levels without inducing clinical hypothyroidism; the significance of this is unknown.

Administration to patients with nephrotic syndrome should be avoided.

Androgens should be used cautiously in young boys to avoid possible premature epiphyseal closure or precocious sexual development.

Androgen therapy should only be used in male hypogonadism in which testosterone levels have been demonstrated to be low.

Adverse reactions: Testosterone Implants, like any other androgen therapy, may give rise to the following adverse reactions.

- priapism and other signs of excessive sexual stimulation.
- phallic enlargement and increased frequency of erections in prepubertal males.
- sodium and water retention after prolonged administration of very high dosages.
- oligospermia and a decreased ejaculatory volume after prolonged administration of very high dosages.
- virilisation (e.g. hoarseness of the voice, acne, hirsutism) enlarged clitoris and stimulation of libido.
- menstrual irregularities in female patients.

Treatment should be interrupted until these symptoms have disappeared, after which it should be continued at a lower dosage.

Hoarseness of the voice may be the first symptom of vocal change which may lead to irreversible lowering of the voice; if signs of virilisation, particularly lowering of the voice, develop, treatment should be discontinued.

Interactions: Concurrent administration of liver enzyme inducing drugs such as rifampicin, barbiturates, phenylbutazone or phenytoin may decrease the effect of Testosterone Implants.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Each sterile implant is supplied singly, in a sealed glass tube. Available in 100 mg and 200 mg weights.

Further information Nil.

200 mg 0065/5084

TETRABID-ORGANON*

Presentation Hard gelatin capsules (purple cap/yellow body).

Active ingredient: Each capsule contains Tetracycline Hydrochloride 250 mg.

Uses Tetrabid-Organon is a sustained-action tetracycline formulation which requires only half the daily dose and half the frequency of administration of conventional tetracycline. Indicated for the treatment of all infections caused by organisms sensitive to tetracycline, bronchitis and for the treatment and prophylaxis of acute exacerbations of chronic bronchitis. Tetrabid-Organon is also indicated in the treatment of acne vulgaris.

Dosage and administration *Adults and children over 12 years:* Two capsules initially, followed by one capsule every 12 hours. For more severe infections, dosage may be increased at the discretion of the physician. Treatment should continue for at least two or three days after achievement of the desired clinical response, and should continue for at least two months in the prophylaxis of acute exacerbations of chronic bronchitis.

In the treatment of acne vulgaris: One capsule daily for at least three months.

Capsules should preferably be taken one hour before, or two hours after meals.

Contra-indications, warnings, etc

Contra-indications: Contra-indicated in patients with a history of tetracycline sensitivity, pregnancy (unless specifically indicated by bacterial sensitivity tests and where the risk involved is justified) and during lactation. Tetrabid-Organon should not be administered to children under seven years of age.

Precautions and warnings: Tetracycline should be administered with caution in patients with renal or hepatic impairment; a reduction of the dosage or a greater interval between the administration of the capsules may be indicated.

Tetracycline is selectively taken up in developing bones and teeth of foetus and children, causing dental staining and enamel hypoplasia.

Broad-spectrum antibiotic therapy may result in overgrowth of non-susceptible organisms. If such superinfection should occur the antibiotic therapy should be discontinued and appropriate measures taken.

In long-term therapy, laboratory monitoring of certain functions (including haemopoietic, renal and hepatic studies) should be performed.

Adverse reactions: Skin photosensitivity reactions are occasionally observed in patients on tetracycline therapy. Treatment should be discontinued at the first evidence of skin erythema.

The incidence of adverse reactions such as nausea, vomiting and diarrhoea, is low.

Interactions: Antacids, iron haematinics and zinc sulphate have been reported to impair the intestinal absorption of tetracycline. Therefore doses of one preparation should be spaced as far as possible from the other.

Concurrent use of milk products interferes with absorption of tetracyclines to a variable degree, and should be avoided.

Since bacteriostatic drugs may interfere with the bactericidal action of penicillin, it is advisable to avoid administering tetracycline in conjunction with penicillin.

In general, the physician should be aware that interactions may occur when tetracycline is administered concomitantly with various drugs. In addition, tetracycline has been reported to interfere with some diagnostic tests.

Because the tetracyclines have been shown to depress plasma prothrombin activity, patients who are on anticoagulant therapy may require a reduction of their anticoagulant dosage.

Pharmaceutical precautions Store at a temperature below 30°C and in dry conditions. Capsules should not be used after the expiry date shown on the pack.

Legal category POM.

Package quantities Securitainer of 100 or 500 capsules.

Further information Twice-daily Tetrabid-Organon provides economical tetracycline therapy with a reduced incidence of side-effects. The formulation allows sustained release of tetracycline throughout the gastrointestinal tract and Fumaric Acid (33 mg) provides a localised low pH environment at the point of release which favours increased absorption.

Product licence number 0065/0028.

TRISEQUENS* ▼

Presentation Trisequens is supplied in a calendar dial-pack of 28 sequential tablets as follows:

(a) 12 blue biconvex tablets marked NOVO 270 on one side, blank on the other side, with a diameter of 6 mm, each containing 2 mg oestradiol and 1 mg oestriol.

(b) 10 white biconvex tablets, marked NOVO 271 on one side, blank on the other side, with a diameter of 6 mm each containing 2 mg oestradiol, 1 mg oestriol and 1 mg norethisterone acetate BP.

(c) 6 red biconvex tablets, marked NOVO 272 on one side, blank on the other side, with a diameter of 6 mm, each containing 1 mg oestradiol and 0.5 mg oestriol.

Uses Indicated for the treatment of symptoms due to oestrogen deficiency.

Dosage and administration Trisequens is administered orally, one tablet daily without interruption. Regular withdrawal bleeding will become established, usually during the administration of the low-oestrogen tablets, i.e. the 6 red tablets or possibly even during the last phase of the white tablets. In menstruating women, the first tablet should be taken on the fifth day of bleeding. Patients with menorrhagia or metrorrhagia should be curettaged and the first tablet taken on the fifth day afterwards. Patients with oligomenorrhoea may start therapy on the fifth day of bleeding or in cases of very long intervals between bleeding, therapy may commence at any time. Other patients may start at any time.

Contra-indications, warnings, etc

Contra-indications:

1. Known or suspected mammary or genital carcinoma.
2. Known or suspected oestrogen-dependent tumours.
3. Thrombophlebitis, thromboembolic disorders, or patients with a past history of these conditions.
4. Undiagnosed irregular vaginal bleeding.
5. Acute or chronic liver disease or history of liver disease where the liver function tests have failed to return to normal. Jaundice or history of jaundice in pregnancy. Rotor syndrome or Dubin-Johnson syndrome.
6. Haemoglobinopathies or sickle-cell anaemia.
7. Porphyria.
8. Hyperlipoproteinaemia, especially in the presence of other risk factors which may indicate a predisposition to cardiovascular or cerebrovascular disorders.
9. Pregnancy or suspected pregnancy.
10. A history during pregnancy of severe pruritus, herpes gestationis or a deterioration of otosclerosis.
11. Existing cerebrovascular or cardiovascular disease.

Precautions and Warnings: Before the initiation of therapy with Trisequens, it is advisable to undertake a thorough examination to exclude any possibility of genital or mammary tumours. A similar examination is

advisable at regular intervals throughout therapy, e.g. every 6 months. Special attention should be paid to duration of the cycle, body weight, blood pressure, heart, breasts, pelvic organs, legs and skin.

There is some evidence that obesity and possibly hypertension or diabetes mellitus, are predisposing factors to endometrial carcinoma. In view of this, special care should be taken in the presence of these conditions and also if a family history of endometrial carcinoma is present.

Patients with epilepsy, migraine, diabetes, asthma or cardiac dysfunction should be carefully controlled as oestrogens may worsen these conditions.

The indications for immediate withdrawal of therapy are as follows: thrombophlebitis, thromboembolic disorders, the appearance of jaundice, the occurrence of migraine-like headaches, sudden visual disturbances, or a significant increase in blood pressure. It is also advisable to withdraw treatment 6 weeks before elective surgery and during prolonged periods of immobilisation.

If abnormal irregular bleeding occurs during therapy diagnostic aspiration biopsy or curettage should be performed to rule out the possibility of uterine malignancy. (See also Dosage and Administration.)

Treatment may be stopped at approximately 6–12 monthly intervals to establish whether continued therapy is still required.

Trisequens has no contraceptive effect.

A decreased glucose tolerance may occur in diabetic patients on this treatment, and their control must be carefully supervised.

Studies in animals have indicated that administration of very high doses of oestrogen and/or progestogens will induce neoplastic tumours in some animal species. The relevance to man is unknown.

The results of recent studies in human beings suggest that there is a small but statistically increased incidence of endometrial carcinoma and of mammary carcinoma in women who have been receiving oestrogens in *high daily dosage over a prolonged period*. Combination with progestogen is not shown to be associated with an increased risk of endometrial carcinoma or mammary carcinoma.

Studies in animals, in particular the dog, have demonstrated that the progestogens including progesterone will induce neoplastic mammary tumours. Recent investigations suggest that results of dosing studies with progestogen in the dog are irrelevant to the potential for such effects in human beings, because of differences in mammary receptor susceptibility and responses.

Pre-existing uterine fibromyomata may increase in size under the influence of oestrogens and if this is observed administration of the preparation should be discontinued.

Side effects: There has only been a low incidence of side effects. Nausea occurs only rarely and oedema is infrequent. Breast tenderness or bleeding irregularities may occur especially during the first few months of treatment. Changes in weight may be seen, but the clinical evidence shows no clear tendency towards either weight increase or decrease. Blood pressure remains unchanged or shows a slight decrease during therapy.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Trisequens is supplied in a calendar dial-pack of 28 tablets.

Further information Total plasma oestrogen levels are restored thus causing a decrease or complete disappearance of subjective oestrogen deficiency symptoms. Suppression of subjective symptoms such as vasomotor disturbances and psychogenic disorders may primarily be ascribed to the oestradiol component. The anatrophy effects on the cervix and vagina may be ascribed both to the oestriol and oestradiol component.

A regular withdrawal bleeding is established with Trisequens due to the addition of norethisterone acetate in the second series of (white) tablets which induce a change in the endometrium to a secretory phase, followed by endometrial shedding usually during the third series of (red) tablets. The low oestrogen contents in the last series of tablets prevent the reappearance of symptoms without affecting withdrawal bleeding.

Product licence number 0065/0065.

***Trade Mark**

PAVULON®

Presentation Pancuronium bromide BP 2 ml ampoules. A clear, aqueous solution. Active ingredient: Each 2 ml ampoule contains pancuronium bromide BP 4 mg. Other ingredients: sodium chloride BP 16 mg, acetate buffers to pH 4, 1% benzyl alcohol.

Uses Pavulon is a neuromuscular blocking agent of the non-depolarising type with a medium duration of action. It is used as an adjuvant in surgical anaesthesia to obtain relaxation of the skeletal muscles in a wide range of surgical procedures.

Pavulon is also used for neuromuscular blockade during intensive care therapy for a variety of pathologies, including intractable status asthmaticus and tetanus. Pavulon is the relaxant of choice when other muscle relaxants might be inappropriate, e.g. shock, allergy, renal and hepatic insufficiency.

Dosage and administration Pavulon is usually administered by intravenous injection (but see recommendations for use in the intensive care patient, below). When calculating dosages of neuromuscular blocking agents the following factors must be taken into account: the anaesthetic technique used, the anticipated duration of the operation, potential interactions with the drugs used during (and before) anaesthesia, and the condition of the individual patient. The following may be used as a general guide to dosage:

General guide to dosage:

Adult surgery: Initial dose: 0.05–0.08 mg/kg (intubation accomplished within 150–120 seconds) or 0.08–0.1 mg/kg (intubation accomplished within 120–90 seconds). Incremental doses: 0.01–0.02 mg/kg.

Child surgery: Initial dose: 0.06–0.1 mg/kg. Incremental doses: 0.01–0.02 mg/kg.

Neonatal surgery: 0.03–0.04 mg/kg intravenously. Incremental doses: As neonates are sensitive this dose should be adjusted according to the initial response but generally incremental doses lie in the range 0.01–0.02 mg/kg body weight.

Following the administration of suxamethonium:

The dosage of Pavulon may be considerably reduced –

Adult surgery: Initial dose: 0.02–0.06 mg/kg. Incremental doses: 0.01–0.02 mg/kg.

Child surgery: Initial dose: 0.02–0.06 mg/kg. Incremental doses: 0.01–0.02 mg/kg.

If the recommended doses of Pavulon are exceeded this will increase the risk of prolonged neuromuscular block, difficulties with the reversal, and marked side effects. In heavy or obese patients calculation of the dosage of Pavulon on the basis of mg/kg leads to overdosing.

Pavulon is longer-acting in the intensive-care patient, and an intravenous dose of 0.06 mg/kg every one to one and a half hours, or even less frequently, is usually

adequate. It can also be given by intramuscular injection in a dose of 0.03–0.06 mg/kg every one to two hours. Onset of effect by this route is about 10 minutes.

The duration of action depends upon the clinical condition of the patient and the dose administered, but in normal subjects receiving preoperative muscle relaxant doses the duration of action is usually 40–45 minutes.

In the control of tetanus, duration of Pavulon relaxation probably depends on the severity of the spasm: duration of effect can therefore be variable.

Pavulon should not be mixed with other agents in the same syringe, or with solutions for intravenous infusion, as a change in pH may induce precipitation.

Contra-indications, warnings, etc

Contra-indications: Patients with a known hypersensitivity to Pavulon injection.

Concurrent use of a depolarising neuromuscular blocking drug e.g. suxamethonium.

Precautions and warnings: Generally speaking it is advisable to monitor the degree of neuromuscular block. Before the administration of Pavulon conditions such as electrolyte disturbance, altered pH and dehydration should if possible be corrected. Care should be exercised if there is a danger of regurgitation when intubating the patient.

Pavulon should be used with particular care in neonates, in ill or cachectic patients, in the presence of liver disease or obstructive jaundice (resistant to effects of drug) in states with altered plasma protein levels or when there is diminished renal blood flow or renal disease.

Care should be taken in patients with renal insufficiency since Pavulon is partially excreted, unchanged, in the urine.

Pavulon should be used cautiously in patients with a tendency to hypertension, as in adrenogenital syndrome, pheochromocytoma or hypertension caused by renal disease.

Extreme caution should be exercised, and very small doses used, in patients with myasthenia gravis or myasthenic syndrome, unless it is intended to administer prolonged post-operative respiratory assistance. In cases of myopathy (such as dystrophia myotonica), severe obesity, electrolyte disturbances (e.g. excessive potassium loss), altered pH and after poliomyelitis or dehydration, Pavulon should be dosed carefully as unwanted effects may occur. In the presence of liver disease the usual dose should be administered, but in certain cases a higher dose may be required, since, in some patients, there is increased resistance to the action of non-depolarising neuromuscular blocking agents.

In operations requiring hypothermia the neuromuscular blockade of non-depolarising drugs is decreased and increases when re-warming the patient. Hypothermia in neonates, therefore, requires a reduced dosage of Pavulon.

Care should be exercised during pregnancy, particu-

larly during the first 12 weeks. Since the consequences of the use of neuromuscular blocking agents on the developing foetus are extremely difficult to assess, one should carefully consider the advantages and the risks.

Pavulon should be administered only by anaesthetists familiar with its use, and only when facilities for controlled ventilation, insufflation with oxygen and endotracheal intubation are available for immediate use.

Since Pavulon in clinically effective doses affects the respiratory muscles, as well as other skeletal muscles, respiration must be assisted in all patients. It is essential to ensure that the patient is breathing spontaneously, deeply and regularly before leaving the theatre after anaesthesia. The neuromuscular blockade achieved with Pavulon can be reversed with a cholinesterase inhibiting agent (e.g. neostigmine) in an adequate dose, together with atropine as an anticholinergic agent.

Pavulon should be used with extreme caution in patients with acid base disturbances, (particularly metabolic acidosis), or electrolyte imbalance. Hypokalaemia or hypocalcaemia may cause an increased effect.

Pavulon may cause a rise in blood pressure and this should be borne in mind when used concurrently with other agents, e.g. halothane, ketamine.

Special care should be exercised if given to the same patient more than once in 24 hours, as a cumulative effect may develop.

Patients with carcinomatosis especially when associated with bronchial carcinoma may exhibit a marked sensitivity to this agent, and the neuromuscular block produced may respond poorly to neostigmine.

Allergic reactions including bronchospasm and hypotension occur rarely with Pavulon.

Interactions: Prior to surgery and during anaesthesia a number of medicines are commonly administered to the patient. This creates the possibility of interaction. In addition, the condition of the patient may influence the neuromuscular blocking (n.m.b.) activity of Pavulon.

The following medicines and conditions of the patient may interact with the n.m.b. activity of Pavulon:

Administration of depolarising drugs (e.g. suxamethonium chloride) following a non-depolarising drug (e.g. Pavulon) is dangerous.

The non-depolarising drug increases resistance towards the neuromuscular blocking effect of the depolarising drug. Therefore high doses of a depolarising drug are necessary before muscular relaxation can be obtained. These high doses of a depolarising drug may cause endplate desensitisation and prolonged post-operative apnoea. Unlike a non-depolarising block, a depolarising block cannot be overcome by an anticholinesterase agent and may even be worsened.

Recent evidence suggests that alkylating drugs (nitrogen mustards) should be considered a possible hazard when given to patients during anaesthesia involving the use of muscle relaxants.

There is a selective interaction between Pavulon and nitroglycerin in that the latter affects the process of recovery from neuromuscular blockade. When nitroglycerin infusion precedes Pavulon injection prolongation of the blockade will occur.

Care should be taken with anaesthesia involving the use of halothane and Pavulon in patients receiving chronic tricyclic antidepressant therapy, as this predisposes to the development of cardiac arrhythmias.

Anaesthetics: The following anaesthetics may influence the neuromuscular blocking activity of Pavulon:

Increased effect: halothane, ether, enflurane, isoflurane (Forane), methoxyflurane, neurolept analgesia, cyclopropane, propanidid, thiopentone, methohexitone.

Influence on the cardiovascular system: Pavulon does not intensify the hypotension induced by halothane; in addition the cardiac depression is partly restored. The excessive bradycardia induced by neurolept analgesia and some of the cholinergic effects of morphine derivatives are counteracted by Pavulon.

The tachycardia which may be induced by Pavulon can be corrected by Hydergine.

The following drugs may influence the duration of action of Pavulon and the intensity of the neuromuscular block:

Increased effect: other muscle relaxants (e.g. d-tubocurarine), antibiotics of the polypeptide and aminoglycoside groups (e.g. neomycin, streptomycin, kanamycin), diazepam, propranolol, thiamine (high dose), M.A.O. inhibiting agents, quinidine, magnesium sulphate, narcotic analgesics, protamine, nitroglycerin.

Decreased effect: neostigmine, edrophonium, corticosteroids (high dose), adrenaline, potassium chloride, sodium chloride, calcium chloride, heparin (temporary decrease), azathioprine, theophylline.

Condition of the patient: The following conditions may influence the neuromuscular blocking activity of Pavulon:

Increased effect: Hypokalaemia (e.g. after severe vomiting, diarrhoea, digitalisation), hypermagnesaemia, hypocalcaemia (after massive transfusion), hypoproteinaemia, dehydration, acidosis, hypercapnoea, cachexia, myasthenia gravis, myasthenic syndrome, renal and liver failure, profound anaesthesia.

Decreased effect: Hypothermia, hyperdiuresis, superficial anaesthesia.

Disturbances in renal function and hypocalcaemia are factors favouring the development of a syndrome resembling that of myasthenia gravis following administration of antibiotics. A disturbed plasma protein pattern requires prudence. Pavulon (like d-tubocurarine) causes a reduction in the partial thromboplastin time and the prothrombin time.

With respect to the frequently reported interactions involving other non-depolarising neuromuscular blocking agents the anaesthetist should be aware of the possibility that similar interactions may occur with Pavulon.

Side-effects: After Pavulon a slight to moderate rise in arterial pressure may occur. Increased pulse rate and cardiac output are frequently reported, showing Pavulon to have weak vagolytic activity. In general this is considered to be a favourable effect. Pavulon decreases intra-ocular pressure and induces miosis, both effects being favourable in ophthalmic surgery. A few cases of localised reactions at the site of injection have been reported.

Overdosage: In the event of an overdosage the patient should continue to be ventilated, and at the same time receive a cholinesterase inhibiting agent (e.g. pyridostigmine, neostigmine) in an adequate dose, as an antidote.

Pharmaceutical precautions In the pharmacy, Pavulon should be stored in a refrigerator at 0-4°C and protected from light, when it will retain its stability for two years. Pavulon is stable for six weeks at 25°C.

Opened ampoules of Pavulon should be discarded if the contents are not used within a few hours.

Legal category POM.

Package quantities Boxes of 25 ampoules 2 ml.

Further information The active substance of Pavulon is pancuronium bromide, an amino steroid which effectively blocks transmission of motor nerve impulses to the striated muscle receptors. Endplate depolarisation does not occur. Pancuronium bromide has no hormonal activity. An initial dose of Pavulon of 0.08 mg/kg i.v. has a mean onset of action of 45 seconds, a maximum effect after 90–120 seconds, and a mean duration of action of 60 minutes (these data are approximations since, as is well-known, all muscle relaxants display dose-response variability). The potency ratio of Pavulon/d-tubocurarine is approximately 6–7 : 1.

Pavulon is accepted as one of the standard preparations in anaesthesia, and is widely used in all fields of

surgery. It has a smooth onset of action, extremely low toxicity and the virtual absence of such side-effects as histamine release, and although rare instances of bronchospasm have been reported Pavulon has, in general, a lack of associated bronchospasm. There is lack of ganglion blockade and thus no hypotensive effect, unlike some other muscle relaxants.

Pavulon is of considerable value when used in conjunction with halothane, since it helps to counteract the cardiovascular depression normally induced by halothane. Pavulon is particularly suitable for use in poor risk patients and in intensive-care units. Pavulon is used widely with good results in Caesarean section.

Ortho-Cilag Pharmaceutical Limited

PO Box 79, Saunderton
High Wycombe
Buckinghamshire HP14 4HJ.

ACI-JEL* THERAPEUTIC VAGINAL JELLY

Presentation Acetic acid 0.92% w/w in a buffered (pH 4), gel base.

Uses In any case where the restoration and maintenance of vaginal acidity is desirable, as in the treatment of non-specific vaginal infection and in the milder forms of simple cervicitis. Aci-Jel Therapeutic Vaginal Jelly is also useful as an adjunct to systemic therapy in trichomoniasis, and prophylactically after courses of other, more specific therapy.

Dosage and administration One applicatorful intravaginally in the morning and upon retiring. The frequency of the application and duration of treatment depend upon the type of case and the degree of progress.

Contra-indications, warnings, etc None known.

Overdosage: Aci-Jel Therapeutic Vaginal Jelly is intended for intravaginal use. If accidental ingestion of large quantities of the product occurs, an appropriate method of gastric emptying may be used if considered desirable.

Pharmaceutical precautions Store at room temperature.

Legal category GSL.

Package quantities Tube containing 85 g. with or without the ORTHO* Plastic Vaginal Applicator.

Further information Nil.

Product licence number 0076/5015.

BINOVOUM*

Presentation $\frac{1}{2}$ -inch diameter, circular tablets with flat faces and bevelled edges bearing the engraving  on each face. 7 white tablets each containing 0.5 mg Norethisterone BP and 35 mcg Ethinyloestradiol BP, and 14 peach coloured tablets each containing 1.0 mg Norethisterone BP and 35 mcg Ethinyloestradiol BP.

Uses Contraception and the recognised indications for such oestrogen/progestogen combinations.

Action: Through the mechanism of gonadotrophin suppression by the oestrogenic and progestational actions of the ingredients. Although the primary mechanism of action is inhibition of ovulation, alterations to the cervical mucus and to the endometrium may also contribute to the efficacy of the product.

Dosage and administration The basic dosage regimen is a 28 day cycle, of 1 tablet daily for 21 days, followed by 7 tablet-free days. A white tablet is taken every day for 7 days, then a peach coloured tablet is taken every day for 14 days. For initial therapy, the first white tablet is taken on the first day of bleeding of the menstrual cycle. If BiNovum* Tablets are first taken later

than the first day of bleeding of the first menstrual cycle of medication, contraceptive reliance should be not placed on this product until after the first 14 consecutive days of administration.

Subsequent cycles: Each subsequent course is started after 7 tablet-free days have followed the preceding course.

Changing from another combined oral contraceptive: The first white tablet should be taken on the first day of the withdrawal bleed after the completion of the previous course of tablets.

Changing from a progestogen-only contraceptive: The first white tablet should be taken on the first day of bleeding that occurs either during the last course of tablets or following completion of the tablet course.

Post-partum use: After pregnancy, oral contraception may be initiated immediately post-partum in the non-nursing patient or as soon as spontaneous menstruation has been resumed. Another method of contraception should be used in the interval between delivery and the first course of tablets, unless it is started within seven days of delivery. After a miscarriage or first-trimester abortion, oral contraception may be started immediately.

If the patient forgets more than one tablet, she should recommence the course as soon as she remembers, taking the appropriate tablet for that day and omitting any tablets delayed more than 12 hours. She should then use an additional method of contraception until the next withdrawal bleed.

If the patient has vomiting or diarrhoea, absorption of the hormones will be impaired, making it advisable to use an additional reliable method of contraception until her next menstrual period. Should a bleeding fail to occur at the usual time, the possibility of pregnancy should be excluded before starting the next pack.

Contra-indications, warnings, etc

Contraindications: Existing thrombophlebitis, thromboembolic disorders, cerebrovascular disease, myocardial infarction, or a past history of these conditions. Sickle-cell anaemia. Markedly impaired liver function. Congenital or existing disorders of lipid metabolism. Known or suspected carcinoma of the breast. Known or suspected oestrogen-dependent neoplasia. History during pregnancy of idiopathic jaundice, severe pruritus, shingles or deterioration of otosclerosis. Dubin-Johnson syndrome. Rotor syndrome. Undiagnosed abnormal genital tract bleeding. Known or suspected pregnancy.

Warnings: An increased risk of thrombophlebitis, cerebrovascular disorders, myocardial infarction and pulmonary embolism associated with the use of oral contraceptives has been reported in several retrospective case control studies. The increased risk has been estimated in these studies to be approximately 4 to 11 times higher (for cerebral haemorrhage two times higher)

for users when compared to non users. This reported risk according to two of the studies is not related to duration of use nor does it persist after discontinuance according to one of the studies. An interim report of a large scale continuing prospective study has tended to confirm these retrospective studies for thrombophlebitis and possible cerebrovascular disorders. This study also reported that the risk of superficial and deep vein thrombosis was lower in women using preparations containing 50 mcg of oestrogen or less. There may not be full recovery from such disorders and it should be realised that in a few cases they are fatal.

Because of a possible increased risk of post surgical thromboembolic complications in oral contraceptive users, therapy should be discontinued at least six weeks prior to elective surgery. Caution should be exercised in administering oestrogen/progestogen combinations to women with a history of hypertension. An increased risk of surgically confirmed gall bladder disease associated with the use of oral contraceptives has been reported in a retrospective case control study.

Liver tumours, occasionally fatal, have been reported in women using oral contraceptives. These tumours may present as an abdominal mass, intra-abdominal bleeding and/or with signs and symptoms of acute abdomen. These have been reported in short term as well as long term users of oral contraceptives.

A small fraction of the active ingredients in oral contraceptives has been identified in the milk of mothers receiving these drugs. The effects, if any, on the breast-fed child have not been determined. If possible the use of oral contraceptives should be deferred until the infant is weaned.

When women have taken hormones during pregnancy there have been some reports of the possibility of adverse effects on the developing child. A direct relationship between such effects and oral contraceptives has not been confirmed, but as with any other drug, avoidance of continuing oral contraception in early pregnancy is desirable. Therefore pregnancy should be ruled out before initiating or continuing the administration of oral contraceptives to patients who have missed one menstrual period.

Certain factors may entail some risk of thrombosis, e.g. smoking, obesity, varicose veins, cardiovascular diseases, diabetes, and migraine. The suitability of a combined oral contraceptive should be judged according to the severity of such conditions in the individual case, and should be discussed with the patient before she decides to take it. The risk of arterial thrombosis associated with combined oral contraceptives increases with age and this risk is aggravated by cigarette smoking. The use of combined oral contraceptives in women in the older age group, especially those who are cigarette smokers, should therefore be discouraged and alternative methods advised.

Reduced efficacy and increased incidence of breakthrough bleeding have been associated with concomitant use of oral contraceptives and rifampicin. A similar association has been suggested with oral contraceptives and barbiturates, phenylbutazone, phenytoin sodium and ampicillin.

Reasons for stopping oral contraceptives immediately: Early manifestations of thrombotic or thromboembolic disorders, thrombophlebitis, cerebrovascular disorders (including haemorrhage), myocardial infarction, pulmonary embolism or retinal thrombosis. Hypertension. Gradual or sudden, partial or complete loss of vision.

Proptosis or diplopia. Onset or aggravation of migraine or development of headaches of a new pattern which are recurrent, persistent or severe. Papilloedema or any evidence of retinal vascular lesions. During periods of immobility (e.g. after accidents). Pregnancy. Manifestations of liver tumours.

Precautions: Examination of the pelvic organs, breasts and blood pressure should precede the prescribing of any oral contraceptive, and should be repeated regularly.

The following are some of the conditions reported to be influenced by oral contraceptive therapy, and where the physician will have to exercise medical judgement to commence, continue or discontinue therapy as appropriate.

- (a) Pre-existing uterine fibromyomata may increase in size.
- (b) A decrease in glucose tolerance in a significant number of women.
- (c) An increase in blood pressure in a small but significant number of women.
- (d) Cholestatic jaundice. Patients with a history of cholestatic jaundice of pregnancy are more likely to develop cholestatic jaundice during oral contraceptive therapy.
- (e) Amenorrhoea during and after oral contraceptive therapy. Women with a past history of oligomenorrhoea or secondary amenorrhoea or women with irregular cycles may be more likely to remain anovulatory or to become amenorrhoeic post oral contraceptive therapy.
- (f) Depression.
- (g) Fluid retention. Conditions which might be influenced by this factor include epilepsy, migraine, asthma, cardiac or renal dysfunction.
- (h) Varicose veins.
- (i) Multiple sclerosis.
- (j) Porphyria.
- (k) Tetany.
- (l) Wearing of contact lenses.

or any condition that is prone to worsen during pregnancy.

The following laboratory determinations may be altered in patients using oral contraceptives:

Hepatic: Increased BSP retention and other tests.

Coagulation: Increased prothrombin, Factors VII, VIII, IX and X, decreased antithrombin III, increased platelet aggregability.

Endocrine: Increased PBI and butanol extractable protein bound iodine and decreased T³ uptake, increased glucose blood levels.

Other: Increased phospholipids and tri-glycerides, decreased serum folate values and disturbance in tryptophan metabolism, decreased pregnanediol excretion, reduced response to metyrapone test.

These tests usually return to pre-therapy values after discontinuing oral contraceptive use. However, the physician should be aware that these altered determinations may mask an underlying disease.

Side effects: Those most commonly reported in early cycles of oral contraceptive therapy include breakthrough bleeding, spotting, nausea, vomiting and other gastrointestinal disturbances. These frequently decrease with continued use. Other common side-effects include: change in menstrual flow, change in weight, oedema, chloasma (which may persist post therapy), amenorrhoea, breast changes (tenderness, enlargement and secretion).

In addition to the conditions and disorders discussed above, the following have been reported as adverse reactions in patients using combined oral contraceptives:

Neuro-ocular lesions	Haemorrhagic eruptions
Rash	Cystitis-like syndrome
Cervical erosion and secretions	Headache
Suppression of lactation	Nervousness
Pre-menstrual like syndrome	Fatigue
Changes in libido	Hirsutism
Leg cramp	Loss of scalp hair
Relative pyridoxine deficiency	Erythema multiforme
	Erythema nodosum
	Itching
	Vaginal candidiasis
	Porphyria

Overdosage: Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea, and withdrawal bleeding may occur in females. An appropriate method of gastric emptying may be used if considered desirable.

Pharmaceutical precautions Protect from light.

Legal category POM.

Package quantities Carton containing 3 pushpaks each of 21 tablets – sufficient for 3 cycles.

Further information Nil.

Product licence number 0076/0090.

DELLEN* CONTRACEPTIVE CREAM

Presentation Delfen Contraceptive Cream contains nonoxonyl-9 5.0% w/w in a white, oil and water emulsion at pH 4.5.

Uses Delfen Contraceptive Cream is a spermicidal cream for the control of conception. A higher degree of protection against pregnancy will be afforded by using another method of contraception in addition to a spermicidal contraceptive.

Dosage and administration One applicatorful (5 cc) intravaginally prior to coitus. A fresh application must be made if intercourse is repeated or delayed by more than one hour. If a douche is desired, it should be deferred for at least six hours after intercourse.

Contra-indications, warnings, etc Hypersensitivity to the product.

Warnings: Where avoidance of pregnancy is essential the choice of contraceptive should be made in consultation with a doctor or a family planning clinic.

Side-effects: Irritation of the vagina or penis has been reported. In such cases the medication should be discontinued.

Overdosage: Delfen Contraceptive Cream is intended for intravaginal use only, and if taken orally by mistake is likely to taste unpleasant. If excess quantities are swallowed this may give rise to gastric irritation as the product contains a surfactant, and general supportive therapy should be carried out if necessary.

Pharmaceutical precautions None known.

Legal category GSL.

Package quantities Tube containing 70 g.

ORTHO* Plastic Vaginal Applicator available separately.

Further information Nil.

Product licence number 0076/5004.

DELLEN* CONTRACEPTIVE FOAM

Presentation Delfen Contraceptive Foam is a white, non-staining aerosol foam which contains nonoxonyl-9 12.5% w/w and buffered to normal vaginal pH of 4.5.

Uses Delfen Contraceptive Foam is a spermicidal foam for the control of conception. It provides rapid dispersion and extensive, uniform coverage of the cervix. A higher degree of protection against pregnancy will be afforded by using another method of contraception in addition to a spermicidal contraceptive. It is suitable for use with an occlusive device.

Dosage and administration One applicatorful intra-vaginally prior to coitus. A fresh application must be made if intercourse is repeated or delayed by more than one hour. If a douche is desired, it should be deferred for at least six hours after intercourse.

Contra-indications, warnings, etc Hypersensitivity to the product.

Warnings: Where avoidance of pregnancy is essential, the choice of contraceptive should be made in consultation with a doctor or a family planning clinic.

Side-effects: Irritation of the vagina or penis has been reported. In such cases the medication should be discontinued.

Overdosage: Delfen Contraceptive Foam is intended for intravaginal use only, and if taken orally by mistake is likely to taste unpleasant. If excess quantities are swallowed this may give rise to gastric irritation as the product contains a surfactant, and general supportive therapy should be carried out if necessary.

Pharmaceutical precautions Contents are under pressure. Do not burn or puncture container. Store at room temperature, not over 49°C (120°F).

Legal category GSL.

Package quantities 20 g aerosol container with or without the DELLEN* Contraceptive Foam Applicator.

Further information Nil.

Product licence number 0076/5003.

DERMONISTAT* CREAM

Presentation A smooth, white non-staining cream containing miconazole nitrate 2% w/w.

Uses A potent antimycotic cream for the treatment of fungal infections of the skin, hair and nails.

Dosage and administration May be applied topically to both adults and children.

Fungal infections of the skin: The cream should be applied to the lesions twice daily and continued for 10 days after the lesions have disappeared.

Fungal infections of the nail: The cream should be applied thinly to the infected nail once daily and the nail covered with a non-perforated plastic bandage. Nails should be clipped short at regular intervals and treatment continued until the growth of the new nail is established and a definite cure can be observed.

Contra-indications, warnings, etc Hypersensitivity to the product.

Side-effects: Isolated cases of sensitisation and irritation have been reported. If this occurs administration of the product should be discontinued.

Overdosage: Dermonistat Cream is intended for topical use. If accidental ingestion of large quantities of the product occurs, an appropriate method of gastric emptying may be used if considered desirable.

Pharmaceutical precautions None known.

Legal category P.

Package quantities 30 g tubes. A patient-instruction leaflet is enclosed in each package.

Further information Nil.

Product licence number 0076/0041.

GYNO-PEVARYL*150 VAGINAL PESSARIES GYNO-PEVARYL*150 VAGINAL PESSARIES AND CREAM COMBIPACK

Presentation *Pessaries:* White egg-shaped pessaries each containing 150 mg econazole nitrate and melting at 37°C.

Combipack: A combination pack comprising 3 Gyno-Pevaryl vaginal pessaries (each containing 150 mg econazole nitrate) plus a 15 g tube of Gyno-Pevaryl cream (containing 1% econazole nitrate).

Uses *Pessaries:* Vaginitis due to *Candida albicans* and other yeasts.

Combipack: Pessaries for vaginitis; cream for associated vulvitis and to treat the sexual partner to help prevent re-infection.

Dosage and administration *Pessaries:* One pessary should be inserted high into the vagina each evening for three consecutive days.

Combipack: Pessaries as above. The cream should be applied to the vulva and perianal region and/or to the sexual partner's penis, including under the foreskin.

Contra-indications, warnings, etc

Contra-indications: None known.

Side-effects: Rarely, transient local mild irritation may occur immediately after application.

Overdosage: Gyno-Pevaryl Vaginal Pessaries and Cream are intended for intravaginal use. If accidental ingestion of large quantities of the product occurs, an appropriate method of gastric emptying may be used if considered desirable.

Precautions: Hypersensitivity has rarely been recorded, if it should occur, administration of the product should be discontinued.

Gyno-Pevaryl 150 vaginal pessaries are effective in the treatment of vaginal candidiasis associated with pregnancy but as with any new product, caution should be exercised when prescribing during the first trimester.

Pharmaceutical precautions Store in a cool place.

Legal category POM.

Package quantities *Pessaries:* Each pack contains 3 pessaries and a patient instruction leaflet. The pessaries are individually sealed in a white plastic strip marked Gyno-Pevaryl 150 at regular intervals.

Combipack: Each pack contains 3 pessaries, a 15 g tube of cream and a patient instruction leaflet.

Further information Anogenital hygiene is important to help prevent re-infection.

Product licence numbers

Pessaries 0076/0058

Combipack 0076/0058 and 0076/0060

LIPPES LOOP* INTRAUTERINE CONTRACEPTIVE DEVICE

Presentation The Lippes Loop is manufactured from polyethylene in the shape of a double 'S'. Four different sizes are available to allow for the variability in the size of the uterus (see below). A fine double thread 'tail' made of polyethylene suture material (monofilament) is attached to the lower end to facilitate removal. In addition, palpation of the tail in the vagina by the patient, or visualization by the physician, can assist in determining whether or not an undetected expulsion has occurred. The Lippes Loop comes prepacked and sterilized with an introducer and insertion tube in a sealed envelope. The insertion tube is equipped with a flange which is used to determine the depth to which the tube should be inserted through the cervical canal and into the uterine cavity. The four available sizes are as follows:

Loop A – 22.5 mm. Blue thread. For nulliparous patients.

Loop B – 27.5 mm WITH REDUCED RADII. Black thread. Suggested for patients who have experienced premature pregnancy losses, and multiparous patients whose uteri measure less than 6 cm.

Loop C – 30 mm WITH REDUCED RADII. Yellow thread. Suggested for use in patients with one or more children.

Loop D – 30 mm. White thread. Suggested for use in multiparous patients where the risk of expulsion is thought to be greater than usual.

Uses Contraception.

Dosage and administration The Lippes Loop is inserted by a doctor into the patient's uterus. The insertion technique is described on the leaflet provided with each device.

Contra-indications, warnings, etc Contraindications: IUCD's should not be inserted when the following conditions exist:

1. Pregnancy or suspicion of pregnancy.
2. Abnormalities of the uterus resulting in distortion of the uterine cavity.
3. Pelvic inflammatory disease or a history of repeated pelvic inflammatory disease.
4. Postpartum endometritis or infected abortion in the past three months.
5. Known or suspected uterine or cervical malignancy including unresolved abnormal cervical smear.
6. Genital bleeding of unknown aetiology.
7. Cervicitis, until infection is controlled.
8. Large or multiple fibroids.
9. Menorrhagia and/or intermenstrual bleeding.
10. Severe dysmenorrhoea.

Warnings:

1. Pregnancy:
 - (a) Long-term effects: Long-term effects on the offspring, when pregnancy occurs with the Lippes Loop *in situ*, are unknown.

(b) Septic abortion: Reports have indicated an increased incidence of septic abortion associated in some instances with septicaemia, septic shock, and, rarely, death in patients becoming pregnant with an IUCD *in situ*. Most of these reports have been associated with the mid-trimester of pregnancy. In some cases the initial symptoms have been insidious and not easily recognised. If pregnancy should occur with an IUCD *in situ*, it is recommended that the IUCD be removed if the thread is visible. If the thread is not visible or device removal proves to be or would be difficult, the IUCD may be left *in situ* until the pregnancy goes to term or until a decision is made to terminate the pregnancy.

(c) Continuation of pregnancy: If the patient chooses to continue the pregnancy with the IUCD *in situ* there is an increased risk of spontaneous abortion and of sepsis, including, rarely, death. If the pregnancy is continued the patient should be closely observed and advised to report immediately all abnormal symptoms, such as flu-like syndrome, fever, abnormal cramping and pain, bleeding or vaginal discharge. The onset of septicaemia may be insidious with general symptoms rather than initial signs of spontaneous abortion.

2. Ectopic Pregnancy:

(a) A pregnancy that occurs with an IUCD *in situ* is more likely to be ectopic than a pregnancy occurring without an IUCD *in situ*. Accordingly, patients who become pregnant whilst using the IUCD require careful evaluation for the possibility of an ectopic pregnancy.

(b) Special attention as to whether an ectopic pregnancy has occurred is required for patients with delayed menses, slight metrorrhagia, and/or unilateral pelvic pain and for patients who wish to terminate the pregnancy with the device *in situ*.

3. Pelvic Infection: An increased risk of pelvic infection has been reported with the IUCD *in situ*. This, at times, may result in the development of bilateral or unilateral tubo-ovarian abscesses or general peritonitis which may lead to infertility if left untreated. Appropriate aerobic and anaerobic bacteriological studies are indicated at the time of initiation of antibiotic therapy. Removal of the IUCD is advised with reassessment of continuing treatment, based upon these bacteriological and sensitivity tests.

4. Embedding: Partial penetration or embedding of the IUCD in the endometrium may cause subsequent removal to be a difficult procedure.

5. Perforation: Partial or total perforation of the uterine wall or cervix may occur with the use of IUCD's. The possibility of perforation must be kept in mind during insertion and at the time of any subsequent examination. If perforation occurs, the IUCD should be removed. Adhesions, foreign body reactions, and intestinal obstruction may result if an IUCD is left in the peritoneal cavity. It is possible for the IUCD to penetrate the uterine wall at any time following insertion.

Precautions: Prior to insertion of an IUCD, a thorough history and physical examination, including a pelvic examination and Papanicolaou smear, should be performed.

Insertion of an IUCD into a uterine cavity measuring less than 6.5 cm may increase the incidence of expulsion, bleeding, pain and perforation.

The patient should be re-examined within 3 months

after insertion and thereafter at yearly intervals to ensure the device is still *in situ*. The patient should be advised to contact her doctor immediately if she misses a menstrual period or has any other reason to think she may be pregnant.

IUCD's should be used with caution in patients:

- With anaemia.
- Receiving anticoagulant therapy or having any disorder of coagulation.
- Receiving steroid therapy (possible masking of pelvic inflammatory disease should be borne in mind).
- With known or suspected rheumatic or congenital heart disease. The need for appropriate antibiotic cover during insertion of the device should be carefully considered.
- With a history of a previous uterine incision or perforation of the uterus.
- With a history of previous ectopic pregnancy.

Syncope, bradycardia or other neuro-vascular episodes may occur during insertion or removal of IUCD's, especially in patients susceptible to these conditions. The possibility of a seizure being precipitated in a patient suffering from epilepsy, at or shortly after the insertion of an IUCD, should also be borne in mind.

No method of contraception can be described as absolutely effective. In some cases it may be appropriate to recommend the use of an additional reliable method of contraception at mid-cycle.

Time of insertion: The Lippes Loop should be inserted preferably during or immediately after a normal menstrual period. Lippes Loop normally is not inserted until 6 weeks or more after delivery or an abortion.

To remove: To remove the Lippes Loop, pull gently on the exposed tail.

Spontaneous expulsion: Expulsion of the Lippes Loop occurs in some patients spontaneously. This expulsion occurs most frequently during the first or second cycle of use, usually at the time of the menstrual period. Expulsion can, however, occur at any time, even several months after insertion.

Confirmation of the expulsion of the device is necessary prior to inserting a second device. Pregnancy must be ruled out before any method of locating the device is undertaken.

Adverse reactions:

1. **Effect on menstrual patterns:** Post-insertion: Almost all patients will experience varying amounts of vaginal bleeding after insertion of the Lippes Loop. In approximately 25% of patients, post-insertion bleeding should cease in a few days.

Intermenstrual Bleeding: Spotting or light bleeding may occur intermenstrually in approximately 25% of patients in the first cycle following insertion. A few patients may experience mid-cycle spotting for several consecutive cycles.

Menstrual Periods: Variation in the first menstrual period following insertion is frequent. This occurs most often as spotting or a brown discharge for 2 days before the period. The first menstrual flow will be longer and slightly heavier than usual, and occasionally the bleeding may be extremely heavy. If this bleeding persists, consideration may be given to removal of the device. A few patients may have heavier than normal bleeding during the second postinsertion menstrual period. The bleeding pattern usually returns to normal by the third cycle. Pelvic pathology should be considered if heavy bleeding occurs beyond this point.

2. **Cramps:** Insertion of the Lippes Loop in multiparous patients usually causes no pain. Slight cramps lasting a few minutes are reported by about 10% of patients in this group and rarely require analgesic therapy.

In contrast, most nulliparous patients complain of moderate to severe cramps which may last for several days following insertion. Analgesics are often required for relief of discomfort in this group; occasionally, removal of the device may be necessary.

3. **Syncope:** Syncope may occur immediately following insertion, particularly in nulliparous patients; it is uncommon in the multiparous patient. A few minutes in a horizontal position may be needed for stabilisation in some patients.

4. **Pelvic inflammatory disease:** Recent studies have indicated that there may be an increased incidence of pelvic inflammatory disease amongst patients fitted with any intrauterine contraceptive device.

Handling precautions If the seal of the sterile envelope is broken, the device inside should not be used.

Legal category POM. Also available through family planning clinics.

Package Quantities Each sterile Lippes Loop is supplied in a sealed envelope. A 'Direction for the Patient' leaflet is also supplied.

Further information Nil.

MASSE[®] BREAST CREAM

Presentation - A white oil in water cream containing Glycerin, Lanolin, Arachis Oil, Sorbitan monostearate, Glyceryl monostearate, Cetyl alcohol, Stearic acid, Polysorbate 60, Propyl p-hydroxybenzoate, Potassium hydroxide, Purified Water.

Uses For pre-natal and post-natal nipple care. Use pre-natally for preparing the nipples for breast feeding including the massage of flat and inverted nipples. Use post-natally for routine application to the nipples of lactating women.

Dosage and administration *Pre-natal nipple care:* Masse Breast Cream is applied once or twice daily during the last two or three months of pregnancy. A $\frac{1}{2}$ " ribbon of cream is massaged gently into the nipples and the surrounding pigmented area with the fingertips until the cream is absorbed. The massage should be with gentle outward motion from the areola to the apex of the nipple.

Post-natal nipple care: Masse Breast Cream is massaged gently around the nipple and areola after the breast has been cleansed after each nursing.

Contra-indications, warnings, etc Acute mastitis or breast abscess. Lanolin sensitivity.

Overdosage: Masse Breast Cream is intended for topical use. If accidental ingestion of large quantities of the product occurs, an appropriate method of gastric emptying may be used if considered desirable.

Pharmaceutical precautions None known.

Legal category GSL.

Package 28 g tubes. A patient instruction leaflet is enclosed in each package.

Further information Nil.

Product licence number 0076/5009.

MICRONOR[®] ORAL CONTRACEPTIVE TABLETS

Presentation White, $\frac{1}{4}$ inch diameter, circular tablets with flat faces and bevelled edges, bearing on each face the engraving 'ORTHO 0.35'. Micronor Oral Contraceptive Tablets each contain 0.35 mg Norethisterone BP.

Uses Contraception.

Action: Micronor has a progestational effect on the endometrium and on the cervical mucus. The exact mechanism of how it prevents conception has not been confirmed.

Dosage and administration Micronor is administered orally on a continuous daily dosage regimen starting on the first day of menstruation. One tablet is taken at the same time each day, every day of the year, whether menstruation occurs or not. When starting Micronor therapy the patient should be instructed to use an additional reliable non-hormonal method of contraception during the first 14 days of the first cycle.

The non-nursing patient may be prescribed Micronor in the post partum period whether or not menstruation has resumed provided the possibility of pregnancy has been excluded.

The possibility of ovulation and conception prior to initiation of medication should be considered.

Strict adherence to the dosage regimen is important. If the patient should fail to take 1 tablet at the usual time protection is reduced. She should take the missed tablet as soon as she remembers and take the next tablet on the day it is due. When a tablet is missed an additional reliable means of contraception should be used in addition to taking Micronor until her next period occurs.

If the patient does not have a period within 45 days of her last period, pregnancy should be excluded.

If the patient has vomiting or diarrhoea, absorption of the hormone will be impaired, making it advisable to use an additional reliable method of contraception until the next menstrual period.

Contra-indications, warnings, etc Any of the following conditions should be regarded as contra-indications for the use of Micronor. Existing thrombophlebitis, thromboembolic disorders, cerebral vascular disease, myocardial infarction, or a past history of these conditions. Markedly impaired liver function, known or suspected hormone dependent neoplasia, known or suspected carcinoma of the breast, undiagnosed abnormal genital tract bleeding, known or suspected pregnancy.

Warnings: Because of a possible increased risk of post surgery thromboembolic complications in oral contraceptive users, therapy should be discontinued six weeks prior to elective surgery.

Masculinisation of the female foetus has occurred when progestogens have been used in pregnant women, although this has been observed at doses much higher than that contained in Micronor. Pregnancy should be ruled out before continuing administration of Micronor to patients who have gone 45 days without a menstrual period.

small doses of oral steroids should be used. Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established; however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

In infants, long-term continuous topical therapy should be avoided. Adrenal suppression can occur even without occlusion.

Eurax-Hydrocortisone should not be allowed to come into contact with the conjunctiva.

Side-effects: Eurax-Hydrocortisone is generally well tolerated. Only in exceptional cases may the cromolone component give rise to skin sensitisation; in such cases, the preparation should be withdrawn.

Pharmaceutical precautions *Storage:* Protect from heat.

Dilutions: Diluents and additives to this formulation are not recommended.

Legal category POM.

Package quantities Tubes of 30 g.

Further information Cromolone is effective against all common forms of pruritus. The relief it affords sets in rapidly and lasts for approximately 6 hours. Cromolone minimises the risk of secondary skin infection by relieving itching and thus preventing damage to the skin caused by scratching. In addition, cromolone exerts a bacteriostatic action on streptococci and staphylococci. Hydrocortisone possesses anti-inflammatory, anti-allergic, anti-exudative, and anti-pruritic activity. The therapeutic properties of cromolone and hydrocortisone complement one another, the combined preparation being particularly effective in the treatment of eczema and pruritus.

Product licence number 0001/5010.

FABROL* ▼

Presentation Pale yellow orange flavoured granules in sachets containing 200 mg acetylcysteine.

Uses *Mode of action:* Fabrol has an intense mucolytic action on mucoid and mucopurulent secretions, due to its ability to split disulphide bonds in mucus glycoprotein. This property allows it to be used as adjuvant therapy in many clinical conditions characterized by the presence of viscous mucoid or mucopurulent secretions, particularly in the respiratory tract.

Indications: Fabrol is indicated in acute and chronic bronchitis and other respiratory tract infections where the condition is associated with the production of viscous mucus. Given on a long term basis in chronic bronchitis, it progressively improves symptoms due to mucus hypersecretion and substantially reduces the rate of infectious exacerbations.

Dosage and administration

Adults: 1 sachet (200 mg) three times daily.

Children: Up to 2 years: 1 sachet (200 mg) daily.

2-6 years: 1 sachet (200 mg) twice daily.

The granules should be dissolved before administration in a glass of water.

In acute cases a treatment period of 5-10 days is usually adequate but may be extended if necessary.

In chronic bronchitis relief of symptoms may be noticeable after treatment for 1-2 months but treatment

may be continued for up to six months e.g. during the winter season.

Fabrol can be administered concurrently with amoxycillin, doxycillin, and erythromycin. When other oral antibiotics or drugs are required, they should be administered 1-2 hours apart from Fabrol.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to acetylcysteine.

Precautions: Each Fabrol sachet contains the equivalent of 2.70 g sucrose. This should be taken into account when treating diabetic patients.

Side-effects: Nausea, heart-burn, vomiting, urticaria, headache and tinnitus have infrequently been reported but these rarely necessitate withdrawal of treatment.

Pregnancy: The administration of Fabrol during pregnancy is advised only if there are compelling reasons.

Accidental overdosage: There is no specific antidote for Fabrol and treatment is symptomatic. It consists of postural drainage, bronchial suction and supportive therapy as indicated.

Pharmaceutical precautions The addition of other drugs to the Fabrol solution should be avoided.

Legal category POM.

Package quantities Packages of 30 sachets.

Further information Nil.

Product licence number 0001/0092

HYGROTON*

Presentation Pale yellow compressed tablets, containing 50 mg chlorthalidone, approximately 7 mm diameter, flat with bevelled edge and impressed GEIGY on one side, breakline and ZA on the other.

White compressed tablets, containing 100 mg chlorthalidone, 7 mm diameter, flat with bevelled edge and impressed GEIGY on one side, breakline and BA on the other.

Uses Hygroton has been shown to have two separate therapeutic actions:

Diuretic: Following a single oral dose a marked salt and water diuresis is evident within two hours and a maximum effect within 12 hours. This natriuretic activity of Hygroton persists for 48-72 hours.

Antihypertensive: In hypertensive subjects Hygroton lowers both systolic and diastolic pressure, the degree of reduction depending on the original blood pressure of the patient. In general, the higher the blood pressure the greater the fall brought about by Hygroton.

Hygroton is indicated for: Hypertension. Oedema due to cardiac failure, hepatic cirrhosis, nephrosis.

Pathological oedema of pregnancy. Diabetes insipidus.

Dosage and administration Hygroton is given orally in tablet form.

Hygroton tablets should be taken orally as a single daily dose at breakfast time.

Hypertension: In mild to moderate hypertension, 25 mg of Hygroton at breakfast time, increasing to 50 mg if necessary.

In more severe cases Hygroton may be combined with other antihypertensive agents in order to increase their hypotensive effects or to allow the use of a lower dose

of the latter where side-effects are becoming troublesome.

Oedema: 1 to 2 × 100 mg tablets on alternate dates. If preferred the 50 mg tablets may be given on a daily basis. In severe cases of oedema, a single loading dose of 4 × 100 mg Hygroton tablets may be required.

The maintenance dose should be the minimum amount needed to keep the patient free from oedema and may be as low as 100 mg twice weekly.

Pathological oedema of pregnancy: The dose of Hygroton used in the treatment of oedema in pregnancy is similar to that in other forms of oedema.

Diabetes insipidus: Hygroton, when used in the treatment of diabetes insipidus can be used either alone or as an adjunct to treatment with antidiuretic hormone. In either case the usual starting dose is 100 mg twice daily, reducing where possible to a maintenance dose of 50 mg daily.

Potassium supplementation: Potassium supplements may be required in digitalised patients, severe cases of oedema, hepatic cirrhosis and in long-term therapy. In digitalised patients, the dose of digoxin may need to be reduced.

Routine supplementation with potassium is not necessary in patients with uncomplicated hypertension.

Paediatric dosage: The recommended dosage for babies up to 10 kg (22 lb) in weight is 5 mg/kg on alternative days. In older children the recommended dose is 50 mg on alternate days for children up to the age of five years, and 50–100 mg on alternate days for children over the age of five years.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to chlorthalidone.

Severe renal or hepatic insufficiency. Concomitant lithium therapy.

Side-effects: In the majority of patients Hygroton is well tolerated. Side-effects are infrequent and generally mild. Gastro-intestinal disturbances may occasionally occur. In rare cases, especially at the start of treatment, patients may complain of slight dizziness and tiredness, which generally resolves spontaneously or following a temporary reduction in the dosage.

There have also been occasional reports of the occurrence of cardiac arrhythmias, disturbances of vision, allergic skin reactions, neutropenia and thrombocytopenia.

Precautions: As with the use of other sulphonamide-type oral diuretics decreased glucose tolerance, as shown by hyperglycaemia and glycosuria, may occur. Hygroton may occasionally aggravate diabetes mellitus or precipitate diabetes in patients who have not previously displayed symptoms. This condition is usually reversible on cessation of therapy. During prolonged Hygroton therapy regular tests for glycosuria should be carried out and any unexpected polyuria investigated.

Hyperuricaemia may occasionally occur and acute attacks of gout may be precipitated. In cases where prolonged elevation of serum uric acid occurs, the concurrent use of a uricosuric agent will reverse the hyperuricaemia without loss of therapeutic effect.

Hypokalaemia may occur, but in most patients this appears to be of little clinical significance. Muscle weakness, cramps, lassitude and ECG changes are signs of significant potassium depletion which may be remedied by the use of oral potassium supplements (16–40 mEq/day). Supplementary potassium medication is

indicated in the presence of an underlying disease (hepatic cirrhosis) associated with increased potassium excretion or in patients receiving concomitant treatment with digitalis, glucocorticoids or ACTH.

As with all antihypertensive agents a cautious dosage schedule is indicated in patients with severe coronary or cerebral arteriosclerosis. In cases where renal function is impaired, creatinine clearance and the electrolyte balance should be monitored. The marked loss of fluid and electrolytes occurring during long-term treatment with large doses of diuretics may aggravate signs of renal failure.

In patients under treatment with lithium, diuretics should be prescribed with caution, because they diminish the excretion of lithium and thus raise the blood lithium levels. Where lithium has induced polyuria, ingestion of diuretics has been observed to exert a paradoxical anti-diuretic effect.

Pregnancy and lactation: Since Hygroton, like other diuretics, is liable during pregnancy to reduce plasma volume as well as the blood supply to the uterus and placenta, its use in pregnant women calls for careful consideration. Diuretics should not be prescribed as treatment for eclampsia or pre-eclampsia or non-pathological oedema occurring during pregnancy.

Chlorthalidone passes into the breast milk and thus mothers taking Hygroton should refrain from breast-feeding their infants.

Accidental overdosage: Symptoms of overdosage include nausea, weakness, dizziness and disturbances of electrolyte balance. There is no specific antidote, but gastric lavage has been recommended. Supportive treatment aimed at maintaining normal fluid and electrolyte balance is essential.

Pharmaceutical precautions *Storage:* Protect from moisture.

Legal category POM.

Package quantities *Tablets 50 mg:* Containers of 100 and 500.

Tablets 100 mg: Containers of 100 and 500.

Further information Nil.

Tablets 100 mg 0001/5012

HYGROTON®-K

Presentation Round, red, sugar coated tablets of approximately 11.3 mm diameter and imprinted GEIGY on one side, containing 25 mg chlorthalidone BP and 500 mg potassium chloride BP–6.7 mEqK (controlled release).

Uses Hygroton has been shown to have two separate therapeutic actions.

Diuretic: Following a single oral dose, a marked salt and water diuresis is evident within two hours and a maximum effect within 12 hours. The natriuretic activity of Hygroton persists for 48–72 hours.

Antihypertensive: In hypertensive subjects Hygroton lowers both systolic and diastolic pressure, the degree of reduction depending on the original blood pressure of the patient. In general the higher the blood pressure the greater the fall brought about by Hygroton.

Potassium supplementation: Hygroton-K contains 500 mg controlled release potassium chloride providing 6.7 mEqK.

Hygroton-K is indicated for the same conditions as for Hygroton but particularly where the physician believes that potassium supplementation is indicated, as in the long-term treatment of hypertension, oedema due to cardiac failure, hepatic cirrhosis, nephrosis, pathological oedema of pregnancy, diabetes insipidus and patients receiving concomitant medication with digitalis, glucocorticoids or ACTH.

Dosage and administration Hygroton-K tablets should be swallowed whole with meals and not chewed.

Hypertension: In mild to moderate hypertension, 1 tablet of Hygroton-K at breakfast time, increasing to 2 tablets if necessary.

In more severe cases Hygroton-K may be combined with other antihypertensive agents in order to increase their hypotensive effect, or to allow the use of a lower dose of the latter, where side-effects are becoming troublesome.

Oedema: 1 or 2 tablets of Hygroton-K once or twice daily. The maintenance dose should be the minimum amount needed to keep the patient free from oedema.

Pathological oedema of pregnancy: The dosage of Hygroton-K is similar to that used in other forms of oedema.

Diabetes insipidus: When Hygroton is indicated for maintenance or as an adjunct to maintenance with antidiuretic hormone the determined dose of Hygroton may be given as Hygroton-K if potassium supplementation is desired.

Where possible the maintenance dose of Hygroton-K should be 2 tablets daily.

Paediatric dosage: Hygroton-K tablets must be swallowed whole and not crushed. Consequently this dosage form of Hygroton is not convenient for paediatric use.

Contra-indications, warnings, etc

Contra-indications: Hypersensitivity to chlorthalidone. Hyperkalaemia. Severe renal or hepatic failure. Concomitant lithium therapy.

All solid dosage forms of potassium salts are contra-indicated in patients suffering from obstructions in the digestive tract (e.g. oesophageal compression due to enlargement of the left atrium, stenosis of the gut).

Side-effects: In the majority of patients Hygroton-K is well tolerated. Side-effects are infrequent and generally mild. Gastro-intestinal disturbances may occasionally occur. In rare cases, especially at the start of treatment, patients may complain of slight dizziness and tiredness, which generally resolves spontaneously or following a temporary reduction in the dosage.

There have also been the occasional reports of the occurrence of cardiac arrhythmias, disturbances of vision, allergic skin reactions, neutropenia and thrombocytopenia.

Hygroton-K tablets are designed to minimise gastrointestinal irritation. However, complaints of abdominal pain, distension, nausea, vomiting or gastro-intestinal bleeding are indications for stopping treatment with potassium containing preparations immediately.

Precautions: As with the use of other sulphonamide type diuretics, decreased glucose tolerance as shown by hyperglycaemia and glycosuria may occur. Hygroton may occasionally aggravate diabetes mellitus or precipitate diabetes in patients who have not previously

displayed symptoms. This condition is usually reversible on cessation of therapy. During prolonged Hygroton therapy regular tests for glycosuria should be carried out and any unexpected polyuria investigated.

Hyperuricaemia may occasionally occur and acute attacks of gout may be precipitated. In cases where prolonged elevation of serum uric acid occurs the concurrent use of a uricosuric agent will reverse the hyperuricaemia without loss of therapeutic effect.

Muscle weakness, cramps, lassitude and ECG changes are signs of significant potassium depletion which may be remedied by adding additional oral potassium supplements.

When Hygroton-K is used particular care should be taken not to combine it with potassium sparing diuretics.

As with all antihypertensive agents a cautious dosage schedule is indicated in patients with severe coronary or cerebral arteriosclerosis.

In cases where renal function is impaired, creatinine clearance and the electrolyte balance should be monitored. The marked loss of fluid and electrolytes occurring during long-term treatment with large doses of diuretics may aggravate signs of renal failure.

In patients under treatment with lithium, diuretics should only be prescribed with caution, because they diminish the excretion of lithium and thus raise the blood lithium levels. Where lithium has induced polyuria, ingestion of diuretics has been observed to exert a paradoxical anti-diuretic effect.

Pregnancy and lactation: Since chlorthalidone, like other diuretics, is liable during pregnancy to reduce plasma volume as well as the blood supply to the uterus and placenta, its use in pregnant women calls for careful consideration. Diuretics should not be prescribed as treatment for eclampsia or pre-eclampsia, or non-pathological oedema occurring during pregnancy.

As chlorthalidone passes into the breast-milk, mothers taking Hygroton-K should refrain from breast-feeding their infants.

Accidental overdose: Symptoms of Hygroton overdose include nausea, weakness, dizziness and disturbances of electrolyte balance. There is no specific antidote but gastric lavage has been recommended.

Supportive treatment aimed at maintaining normal fluid and electrolyte balance is essential. Particular care should be taken to prevent serum potassium levels from exceeding normal values.

Pharmaceutical precautions Protect from heat and moisture.

Legal category POM.

Package quantities Containers of 100 and 250 tablets.

Further information *Note* - Hygroton-K alone is not considered to be effective therapy for hypokalaemia from any cause.

Product licence number 0001/0059.

LAMPRENE*

Presentation The active ingredient, clofazimine, is presented as: red-brown, soft gelatin capsules, containing 100 mg clofazimine in each capsule.

Uses Antileprotic agent:

Prevention of the development of *M. leprae* resistant

to sulphones, in patients with lepromatous and borderline leprosy.

Prevention of lepra reactions in patients with lepromatous and borderline leprosy.

Treatment for lepromatous and borderline forms of leprosy resistant to sulphones.

Treatment of lepra reactions e.g. Erythema nodosum leprosum (ENL).

Treatment of *M. ulcerans* infection (Buruli ulcer).

Dosage and administration For the treatment of leprosy, Lampréne should be employed in combination with other suitable anti-leprosy agents.

The capsules should preferably be taken during meals or together with milk. The dosage of Lampréne must be adapted to the patient's body weight and to the state of activity of the disease.

For the prevention of resistance to sulphones and for the prevention of lepra reactions in cases of lepromatous and borderline leprosy: 50–100 mg Lampréne daily or 100 mg 3 times weekly, during the first 4–6 months of long-term treatment with dapsone (50–100 mg daily).

In cases resistant to sulphones: Long-term treatment with Lampréne in a dosage of 100 mg daily, combined during the first 2–3 months with rifampicin 600 mg daily.

In lepra reactions: If lepra reactions (e.g. ENL) occur, the basic therapy given hitherto should be continued. To suppress the lepra reactions, Lampréne should be administered under surveillance in relatively large, individually determined doses. The dosage generally recommended is one of 300 mg daily for 3 months. As soon as the lepra reaction has been brought under control, the dosage should be gradually lowered to a level at which its suppressant effect is still just sufficient.

Contra-indications, warnings, etc

Contra-indications: There are no known conditions in which Lampréne would be contra-indicated.

Precautions: Treatment with Lampréne should be given only under medical supervision. Daily doses of 300 mg or more should not be administered for longer than 3 months.

If gastro-intestinal symptoms develop during treatment with Lampréne, the dosage should be reduced or the interval between doses prolonged. In the event of persistent diarrhoea or vomiting, the patient should be hospitalised.

During long-term medication with Lampréne, as well as in patients with a history of liver or kidney disease, it is advisable to perform clinical examinations and hepatic or renal tests every 3 months. The use of Lampréne in patients complaining of recurrent abdominal pains, or suffering from damage to the liver or kidneys, should wherever possible be avoided.

Pregnancy: For general medical reasons, it is not advisable to prescribe Lampréne during the first three months of pregnancy unless the drug's use is urgently indicated. The active substance of Lampréne crosses the placental barrier; newborn infants of women under treatment with the drug may therefore show relatively pronounced discolouration.

Side-effects: Lampréne is generally well tolerated. The side-effects occasionally met with are mostly of a mild nature and disappear after the daily dose has been reduced or the medication withdrawn.

The following side-effects have been observed:

Red to brownish-black discolouration of the skin and of the leprosy lesions in lighter-skinned patients at sites

exposed to light; discolouration of the hair, the conjunctiva, and the lacrimal fluid, as well as discolouration of sweat, sputum, urine and faeces.

Dryness of the skin, ichthyosis, pruritus, photosensitivity, acneiform eruptions and non-specific skin rashes. Nausea, vomiting, abdominal pains, diarrhoea, anorexia, and loss of weight are sometimes encountered. These occur mainly in the presence of accompanying gastro-intestinal disease (e.g. amoebiasis or bacterial infections of the gut) or in cases where large daily doses (>300 mg) have been given for a prolonged period (>3 months).

Accidental overdosage: There is no specific antidote for Lampréne and treatment is symptomatic.

Pharmaceutical precautions *Storage:* Protect from heat and moisture.

Legal category POM.

Package quantities *Capsules:* Containers of 100.

Further information Lampréne (clofazimine) is a highly active preparation which exerts a potent inhibitory effect on the growth of *Mycobacterium leprae* (Hansen's bacillus) and which almost invariably also elicits good effects in patients intolerant of, or resistant to, other anti-leprosy drugs. During long-term treatment with sulphone preparations, Lampréne serves to guard against the development of resistance. No cross-resistance between Lampréne and either dapsone or rifampicin has been reported.

Lampréne also possesses anti-inflammatory properties and is suitable for treating lepra reactions occurring in the course of treatment with other drugs. Not only can such reactions be suppressed by administering Lampréne, but in patients previously requiring corticosteroid therapy it is possible to reduce the dosage of corticosteroids gradually and finally to withdraw them completely. During treatment with sulphone preparations, concomitant administration of Lampréne reduces the frequency of lepra reactions.

In rare cases where lepra reactions also occur under treatment with Lampréne, they can be combated by temporarily increasing the dosage.

Product licence number 0001/5041.

LOPRESOR®

Presentation The active ingredient metoprolol tartrate is presented as: pale red, round, slightly biconvex, film-coated tablets with slightly bevelled edges: approximately 9 mm diameter, engraved GEIGY on one side and scored on the other side. Each tablet contains 50 mg.

Lopresor is also available as: light blue, round, slightly biconvex, film-coated tablets with slightly bevelled edges: approximately 10 mm diameter, engraved GEIGY on one side and scored on the other. Each tablet contains 100 mg.

Uses Beta-adrenergic receptor blocking agent.

Indications: Hypertension and angina pectoris, cardiac arrhythmias, especially supraventricular tachyarrhythmias. Adjunct to treatment of thyrotoxicosis.

Dosage and administration *Administration:* Lopresor tablets should be administered orally.

Dosage: Hypertension: Initially a dose of 100 mg in the morning should be prescribed.

Depending upon the response the dosage may be increased to 400 mg daily given in single or divided doses. Over the dosage range most patients may be expected to respond rapidly and satisfactorily. A further reduction in blood pressure may be achieved if Lopresor is used in conjunction with an antihypertensive diuretic such as chlorthalidone or a vasodilator such as hydralazine.

Lopresor may be administered with benefit both to previously untreated patients with hypertension and to those in whom the response to previous therapy is inadequate. In the latter type of patient the previous therapy may be continued and Lopresor added in to the regime with adjustment of the previous therapy if necessary.

Angina Pectoris: 50–100 mg, twice or three times daily.

In general a significant improvement in exercise tolerance and reduction of anginal attacks may be expected with a dose of 50–100 mg twice daily.

Cardiac arrhythmias: A dosage of 50 mg two or three times daily is usually sufficient. If necessary the dose can be increased up to 300 mg per day administered in divided doses.

Following the treatment of an acute arrhythmia with Lopresor Injection (see separate Data Sheet) continuation therapy with Lopresor tablets should be initiated 4–5 hours later. In such cases, the initial oral dose should not exceed 50 mg three times daily.

Thyrotoxicosis: 50 mg four times daily.

If it becomes necessary to discontinue treatment with a beta-blocker, one should withdraw the drug gradually, i.e. over a period of 8–10 days, because abrupt interruption of the medication – particularly in cases of ischaemic heart disease – may be followed by an acute deterioration in the patient's condition.

Contra-indications, warnings, etc

Contra-indications: Atrioventricular block of second or third degree, uncontrolled heart failure, severe bradycardia and cardiogenic shock.

Precautions: Metoprolol has proved safe in a large number of asthmatic patients: although it is a selective beta-blocker it is prudent to exercise care in the treatment of patients with chronic obstructive pulmonary disease. Therapy with a β_2 -stimulant may become necessary or current therapy require adjustment.

Lopresor must not be used in patients with untreated heart failure, but may be administered when the failure has been brought under control. Where heart failure appears during treatment with Lopresor the drug may be temporarily withdrawn until the failure has been controlled.

Lopresor should be given cautiously to patients with metabolic acidosis.

Lopresor may mask some of the symptoms of hypoglycaemia. Since treatment with a beta-blocker may affect carbohydrate metabolism, it may be necessary to adjust the dose of the hypoglycaemic agent in labile and insulin dependent diabetics.

Lopresor therapy should be brought to the attention of the anaesthetist prior to general anaesthesia. In a patient under beta-blockade, the anaesthetic selected should be one exhibiting as little negative inotropic activity as possible (halothane/nitrous oxide).

Like other beta-blockers, Lopresor should not be given in combination with antiarrhythmic agents of the verapamil type because their concomitant use may result in bradycardia, hypotension or even cardiac arrest.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenoceptor blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuance of the beta-adrenoceptor blocking drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-blocker should be gradual.

Pregnancy: The administration of Lopresor during pregnancy, as with other drugs is advised only if there are compelling reasons. If Lopresor is used during pregnancy and lactation special attention should be paid to the foetus, neonate and breast fed infant for undesirable effects of the drug's beta-blocking action (e.g. slowing of heart rate).

Side-effects: Gastro-intestinal upsets; sleep disturbances and exertional tiredness may occasionally occur. In most cases these effects have been transient or have disappeared after a reduction in dosage. In rare cases, feelings of coldness in the extremities may occur. As with other beta-blockers excessive bradycardia may occasionally occur; bronchospasm and heart failure may occasionally be precipitated in susceptible patients.

Accidental overdosage: The symptoms of overdosage will be marked bradycardia and possible hypotension. Bradycardia may be overcome by the administration of intravenous atropine sulphate (0.25–2.0 mg) which will decrease vagal tone. If bradycardia persists sympathomimetic drugs such as metaraminol or noradrenaline should be employed. These drugs have a pressor effect which may also help to overcome hypotension. The positive inotropic and chronotropic properties of glucagon may be useful when it is given in doses of 1–5 mg (max. 10 mg).

Pharmaceutical precautions *Storage:* Protect from heat, light and moisture.

Legal category POM.

Package quantities *Lopresor 50 mg:* Bottles of 100 tablets.

Lopresor 100 mg: Bottles of 100 tablets. Calendar packs of 56 tablets.

Further information Lopresor is a cardioselective beta-adrenergic blocking agent. It has a relatively greater blocking effect on beta₁-receptors (i.e. those mediating adrenergic stimulation of heart rate and contractility and release of free fatty acids from fat stores) than on beta₂-receptors, which are chiefly involved in broncho- and vasodilation.

Lopresor therefore possesses the therapeutically desirable effects of shielding the heart and blood vessels from the harmful effects of excessive adrenergic challenge during stress or exercise with minimal interference with respiratory function or vascular tone.

In hypertension Lopresor is effective during the first few days of treatment and reaches its full effect in a few weeks. No orthostatic hypotension or tendency to collapse has been observed even with fairly high doses.

In angina pectoris Lopresor diminishes the elevation of pulse rate and blood pressure in response to exercise or stress so permitting more efficient use of the oxygen supply to the myocardium. Ischaemic ECG changes are usually prevented or normalised and the patient's capacity for exercise is increased.

Because of its cardioselectivity, Lopresor can be administered even to patients with obstructive respira-

tory disorders, provided that adequate precautions are taken.

Tablets 100 mg 0001/0066

LOPRESOR* INJECTION ▼

Presentation Lopresor ampoules each containing 5 mg metoprolol tartrate in a clear, colourless solution of 5 ml volume.

Uses *Mode of action:* Lopresor is a cardioselective β_1 -receptor blocker exhibiting no intrinsic sympathomimetic activity.

Indications: Beta-adrenergic receptor blocking agent: Disturbances of cardiac rhythm, especially supraventricular tachyarrhythmias.

Dosage and administration Initially up to 5 mg, injected i.v. (1–2 mg/minute). The injection can be repeated at 5 minute intervals until a satisfactory response has been obtained. A total dose of 10–15 mg generally proves sufficient; raising the dose to 20 mg or more does not usually yield better results.

During anaesthesia: 2–4 mg injected slowly i.v. at induction is usually sufficient to prevent the development of dysrhythmias during anaesthesia. The same dosage can also be used to control dysrhythmias developing during anaesthesia. Further injections of 2 mg may be given as required to a maximum overall dose of 10 mg.

The active substance of Lopresor has a plasma half-life of 3–5 hours. The duration of its beta-blocking effect is dose-dependent: 4 hours after intravenous administration of 20 mg Lopresor, for example, its beta-blocking effect in healthy subjects is reduced by one-half.

Contra-indications, warnings, etc

Contra-indications: Atrioventricular block of second or third degree, uncontrolled heart failure, severe bradycardia or cardiogenic shock.

Precautions: Intravenous injections of Lopresor are suitable only for acute administration in hospitalised patients and should be given only if facilities are available for monitoring the electrocardiogram and blood pressure.

The i.v. administration of Lopresor to patients with a systolic blood pressure below 100 mm Hg (13.3 kPa) should only be made with special care as it can result in a further significant decrease of blood pressure.

In a patient under beta-blockade, the anaesthetic selected should be one exhibiting as little negative inotropic activity as possible (e.g. halothane/nitrous oxide).

Metoprolol has proved safe in a large number of asthmatic patients, although it is a selective beta-blocker it is prudent to exercise care in the treatment of patients with chronic obstructive pulmonary disease. Therapy with a β_2 stimulant may become necessary or current therapy require adjustment.

Lopresor must not be used in patients with untreated heart failure, but may be administered when the failure has been brought under control. Where heart failure appears during treatment with Lopresor the drug may be temporarily withdrawn until the failure has been controlled.

Lopresor may mask some of the symptoms of hypoglycaemia. Since treatment with a beta-blocker may affect carbohydrate metabolism, it may be necessary to

adjust the dose of the hypoglycaemic agent in labile and insulin dependent diabetics.

Lopresor should be given cautiously to patients with metabolic acidosis.

Like other beta-blockers, Lopresor should not be given in combination with antiarrhythmic agents of the verapamil type, because their concomitant use may result in bradycardia, hypotension, or even cardiac arrest.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenoceptor blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuance of the beta-adrenoceptor blocking drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-blocker should be gradual.

Pregnancy: The administration of Lopresor during pregnancy as with other drugs is advised only if there are compelling reasons. If Lopresor is used during pregnancy and lactation special attention should be paid to the foetus, neonate and breast fed infants for undesirable effects of the drug's beta-blocking action (e.g. slowing of heart rate).

Side-effects: As with other beta-blockers, a marked fall in blood pressure may sometimes occur following intravenous injection of Lopresor.

Excessive bradycardia may also occasionally occur and bronchospasm and heart failure may occasionally be precipitated in susceptible patients.

Overdosage: The symptoms of overdosage will be marked bradycardia and possible hypotension. Bradycardia may be overcome by the administration of intravenous atropine sulphate (0.25–2.0 mg) which will decrease vagal tone. If bradycardia persists – sympathomimetic drugs such as metaraminol or noradrenaline should be employed. These drugs have a pressor effect which may also help to overcome hypotension. The positive inotropic and chronotropic properties of glucagon may be useful when it is given in doses of 1–5 mg (max. 10 mg).

Pharmaceutical precautions *Storage:* Protect from light.

Legal category POM.

Package quantities Packs of 10 ampoules.

Further information In patients with paroxysmal atrial tachycardia, use of Lopresor often enables normal sinus rhythm to be re-established or the ventricular rate to be reduced. Similarly, in cases of atrial fibrillation or flutter, Lopresor is not only capable of lowering the ventricular rate but, in some instances, may, also restore sinus rhythm. In addition, it diminishes the number of ventricular extrasystoles. When given in therapeutic doses, Lopresor exerts less influence on peripheral blood vessels and bronchial muscle than non-cardioselective beta-blockers. Provided adequate caution is observed it can therefore also be administered in the presence of obstructive pulmonary diseases. When employed at higher dosage ranges, however, Lopresor may in rare cases increase airways resistance in the same manner as other selective beta-blockers.

Product licence number 0001/0086.

LOPRESOR* SR

Presentation The active ingredient metoprolol tartrate

is presented as pale yellow, round, film-coated tablets with slightly convex faces; approximately 10.1 mm diameter, imprinted GEIGY on one side and CDC on the other. Each tablet contains 200 mg metoprolol tartrate in a sustained release formulation.

Uses Selective beta-adrenergic receptor blocking agent.

Indications: Hypertension and angina pectoris.

Dosage and administration *Administration:* Lopresor SR tablets should be administered orally.

Dosage: Hypertension: Initially one Lopresor SR tablet should be given in the morning. Most patients may be expected to respond satisfactorily within 14 days to one or two tablets once daily. Further antihypertensive effect may be achieved by the addition of a diuretic such as chlorthalidone or a vasodilator such as hydralazine.

Lopresor SR may be administered with benefit to both previously untreated patients with hypertension and to those in whom the response to previous therapy is inadequate. In the latter type of patient therapy may be continued and Lopresor SR added to the regime with adjustment of previous therapy if necessary.

Angina pectoris: Initially, one Lopresor SR tablet daily. The dose may be increased to two tablets once daily if required. In general a significant improvement in exercise tolerance and a reduction of anginal attacks may be expected with a dose of one Lopresor SR tablet daily.

Contra-indications, warnings, etc

Contra-indications: Atrioventricular block of second or third degree, uncontrolled heart failure, severe bradycardia and cardiogenic shock.

Precautions: Metoprolol has proved safe in a large number of asthmatic patients, although it is a selective beta-blocker it is prudent to exercise care in the treatment of patients with chronic obstructive pulmonary disease. Therapy with a β_2 stimulant may become necessary or current therapy require adjustment.

Lopresor SR must not be used in patients with untreated heart failure, but may be administered when the failure has been brought under control. Where heart failure appears during treatment with Lopresor SR the drug may be temporarily withdrawn until the failure has been controlled.

Lopresor SR may mask some of the symptoms of hypoglycaemia. Since treatment with a beta-blocker may affect carbohydrate metabolism, it may be necessary to adjust the dose of the hypoglycaemic agent in labile and insulin dependent diabetics.

Lopresor SR should be given cautiously to patients with metabolic acidosis.

Lopresor SR therapy should be brought to the attention of the anaesthetist prior to general anaesthesia. In a patient under beta-blockade, the anaesthetic selected should be one exhibiting as little negative inotropic activity as possible, (e.g. halothane/nitrous oxide).

There have been reports of skin rash and/or dry eyes associated with the use of beta-adrenergic blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuance of the beta-adrenoceptor blocking drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-blocker should be gradual.

Like other beta-blockers, Lopresor SR should not be given in combination with antiarrhythmic agents of the

verapamil type because their concomitant use may result in bradycardia, hypotension or even cardiac arrest.

If it becomes necessary to discontinue treatment with a beta-blocker, one should withdraw the drug gradually i.e. over a period of 8–10 days, because abrupt interruption of the medication – particularly in cases of ischaemic heart disease – may be followed by an acute deterioration in the patient's condition.

Pregnancy: The administration of Lopresor SR during pregnancy as with other drugs is advised only if there are compelling reasons. If Lopresor SR is used during pregnancy and lactation special attention should be paid to the foetus, neonate and breast fed infant for undesirable effects of the drug's beta-blocking action (e.g. slowing of heart rate).

Side-effects: Gastro-intestinal upsets, sleep disturbances and exertional tiredness may occasionally occur. In most cases these effects have been transient or have disappeared after a reduction in dosage. In rare cases, feelings of coldness in the extremities may occur.

As with other beta-blockers excessive bradycardia may occasionally occur, bronchospasm and heart failure may occasionally be precipitated in susceptible patients.

Overdosage: The symptoms of overdosage will be marked bradycardia and possible hypotension.

Bradycardia may be overcome by the administration of intravenous atropine sulphate (0.25–2.0 mg) which will decrease vagal tone. If bradycardia persists, sympathomimetic drugs such as metaraminol or noradrenaline should be employed. These drugs have a pressor effect which may also help to overcome hypotension. The positive inotropic and chronotropic properties of glucagon may be useful when it is given in doses of 1–5 mg (maximum 10 mg).

Pharmaceutical precautions No special precautions.

Legal category POM.

Package quantities Lopresor SR packs of 28 tablets (2 × 14 calendar pack foils).

Further information Lopresor SR is a sustained release preparation of Lopresor (metoprolol tartrate) designed to release this selective beta-adrenergic receptor blocking drug so that maximal response is obtained within 4–6 hours while the pharmacological action is sustained for 24 hours. This formulation reduces peak serum concentration which, in turn, minimises unwanted side-effects of beta-blockade.

Lopresor SR is a cardioselective beta-adrenergic blocking agent. It has relatively greater blocking effects on β_1 receptors (i.e. those mediating adrenergic stimulation of heart rate and contractility and release of free fatty acids from fat stores) than on β_2 receptors which are chiefly involved in broncho- and vasodilation.

Lopresor SR therefore possesses the therapeutically desirable effect of shielding the heart and blood vessels from the harmful effects of extensive adrenergic challenge during stress or exercise with minimal interference with respiratory function or vascular tone.

In hypertension, Lopresor SR is effective during the first few days of treatment and reaches its full effect in fourteen days. No orthostatic hypotension or tendency has been observed even with fairly high doses.

Because of its cardioselectivity, Lopresor SR may be administered even to patients with obstructive respiratory disorders, provided that adequate precautions are taken.

Product licence number 0001/0081.

LOPRESORETIC*

Presentation Off-white, round, bi-convex film-coated tablets with slightly bevelled edges, approximately 10 mm diameter, with a breakline on one face and GEIGY impressed on the other. Each tablet contains metoprolol tartrate (active ingredient of Lopresor*) 100 mg and chlorthalidone BP (active ingredient of Hygroton*) 12.5 mg.

Uses Antihypertensive agent.

Principal therapeutic actions: Lopresor (metoprolol tartrate) is a beta-adrenergic receptor blocking agent which is relatively more selective for beta-1-receptors which mediate heart rate and force of contraction, free fatty acid release and renin production, than for beta-2-receptors which mediate bronchodilation and peripheral vascular dilation. Consequently Lopresor protects the heart and cardiovascular system from excessive sympathetic stimulation caused by either physical or emotional activity while having relatively little effect on the airways or on peripheral vascular responses. The attenuation of the effects of excessive sympathetic drive on the heart result in a fall in myocardial work and oxygen consumption. Systolic pressure is reduced and this is most noticeable in hypertensive subjects, in whom the diastolic pressure is also reduced significantly.

Hygroton (chlorthalidone BP) is a long acting diuretic which lowers both systolic and diastolic pressures in hypertensive patients. In general the higher the initial blood pressure, the greater the fall brought about by Hygroton. The addition of Hygroton enhances the antihypertensive effect of the selective beta-blocker thus resulting in a better control in a higher proportion of patients. This is probably the result of the two active ingredients having different sites of action, Lopresor acting on the heart and possibly also centrally while Hygroton reduces peripheral resistance.

Indications: In the treatment of mild and moderate hypertension.

Dosage and administration *Dosage:* Lopresoretic tablets should be administered orally. Initial starting dose, one tablet in the morning. However, in patients who have not been successfully controlled by a diuretic or beta-blocking drug used alone, a dose of two tablets in the morning would be appropriate. Most patients may be expected to respond within 14 days.

Occasionally the response may be unsatisfactory in which case it may be found beneficial to raise the dosage to 3-4 tablets given in single or divided doses and/or to add a vasodilator such as hydralazine at an initial dose of 25 mg twice daily, increasing as necessary.

Contra-indications, warnings, etc

Contra-indications: Atrioventricular block of second or third degree, uncontrolled heart failure, severe bradycardia, cardiogenic shock and marked renal insufficiency. Anti-diuretic effect has been reported following concomitant treatment with diuretics and lithium. As with all products which contain diuretics, Lopresoretic tablets are contra-indicated during lithium therapy.

Precautions: Metoprolol has proved safe in a large number of asthmatic patients, although it is a selective beta-blocker it is prudent to exercise care in the treatment of patients with chronic obstructive pulmonary disease. Therapy with a β_2 stimulant may become necessary or current therapy require adjustment.

As with other preparations containing beta-blockers, Lopresoretic tablets must not be used in patients with

untreated heart failure, but may be administered when the failure has been brought under control. Where heart failure appears during treatment with Lopresoretic the drug may be temporarily withdrawn until the failure has been controlled.

Lopresoretic may mask some of the symptoms of hypoglycaemia. Since treatment with a beta-blocker may affect carbohydrate metabolism, it may be necessary to adjust the dose of the hypoglycaemic agent in labile and insulin dependent diabetics. Chlorthalidone may also decrease glucose tolerance.

Hyperuricaemia may occasionally occur and acute attacks of gout may be precipitated. Where prolonged elevation of serum uric acid occurs the concurrent use of a uricosuric agent will reverse the hyperuricaemia without loss of therapeutic effect.

Lopresoretic tablets should be given cautiously to patients with metabolic acidosis.

Lopresoretic therapy should be brought to the attention of the anaesthetist prior to general anaesthesia. In a patient under beta-blockade, the anaesthetic selected should be one exhibiting as little negative inotropic activity as possible, (e.g. halothane/nitrous oxide).

If it becomes necessary to discontinue treatment with a beta-blocker one should withdraw the drug gradually i.e. over a period of 8-10 days, because abrupt interruption of the medication - particularly in cases of ischaemic heart disease - may be followed by an acute deterioration in the patient's condition.

Like other beta-blockers, Lopresoretic should not be given in combination with antiarrhythmic agents of the verapamil type because their concomitant use may result in bradycardia, hypotension or even cardiac arrest.

There have been reports of skin rashes and/or dry eyes associated with the use of beta-adrenoceptor blocking drugs. The reported incidence is small and in most cases the symptoms have cleared when treatment was withdrawn. Discontinuance of the beta-adrenoceptor blocking drug should be considered if any such reaction is not otherwise explicable. Cessation of therapy with a beta-blocker should be gradual.

Because of their chlorthalidone content, Lopresoretic tablets should be used with care in patients with some degree of renal impairment.

Pregnancy: The administration of Lopresoretic during pregnancy as with other drugs is advised only if there are compelling reasons. If Lopresoretic is used during pregnancy and lactation special attention should be paid to the foetus, neonate and breast fed infant for undesirable effects of the drug's beta-blocking action (e.g. slowing of the heart).

Side-effects: Gastro-intestinal upsets; sleep disturbances and exertional tiredness may occasionally occur. In most cases these effects have been transient or have disappeared after a reduction in dosage. In rare cases, feelings of coldness in the extremities may occur.

As with other beta-blockers excessive bradycardia may occasionally occur; bronchospasm and heart failure may occasionally be precipitated in susceptible patients.

Like other diuretics with a similar mode of action, chlorthalidone may cause latent gout or latent diabetes mellitus to become manifest. In a few cases, allergic skin reactions, mild anorexia, nausea, constipation and diarrhoea have been reported. There have been isolated reports of leucopenia, but these are rare.

Overdosage: The symptoms of overdosage will be marked bradycardia and possible hypotension. Bradycardia may be overcome by the administration of

intravenous atropine sulphate (0.25–2.0 mg) which will decrease vagal tone. If bradycardia persists – sympathomimetic drugs such as metaraminol or noradrenaline should be employed. These drugs have a pressor effect which may also help to overcome hypotension. The positive inotropic and chronotropic properties of glucagon may be useful when it is given in doses of 1–5 mg (max. 10 mg). Supportive treatment aimed at maintaining normal fluid and electrolyte balance is essential.

Pharmaceutical precautions Protect from moisture.

Legal category POM.

Package quantities Cartons of 56 tablets consisting of blister pack modules each containing 14 tablets (each carton represents 2–8 weeks treatment depending on the dose).

Further information Lopresoretic tablets simplify the management of hypertension since they combine two effective antihypertensive agents which act together in a complementary manner. In addition to the two modes of action already described, the Lopresor component prevents the increase in plasma renin which occurs as a result of diuretic therapy.

Lopresoretic tablets contain a selective beta-blocker and thus can be administered to patients with obstructive respiratory disease provided they have access to a beta-2-stimulant bronchodilator; being a selective agent, Lopresoretic is less likely to interfere with the action of beta-2-stimulants.

Product licence number 0001/0085.

MEDOMIN®

Presentation The active ingredient, Heptabarbitalone, is presented as: white, quarter-scored tablets approximately 11 mm diameter impressed 'Medomin' containing 200 mg heptabarbitalone.

Uses Heptabarbitalone is a barbiturate with a hypnotic action of the intermediate type; if taken in the proper therapeutic dose, it produces sleep for about 3 to 6 hours.

Hypnotic: Insomnia, oral premedication for major and minor surgery.

Dosage and administration Medomin is given orally in tablet form.

Hypnotic dosage: Adults: 1 or 2 tablets. For insomnia tablets should be taken with a warm drink half to one hour before retiring.

Contra-indications, warnings, etc

Contra-indications: Uncontrolled pain. Children and young adults. The elderly and the debilitated. Pregnancy and breast feeding. Patients with a history of alcohol or drug abuse. Porphyria.

Precautions: A reduction in dosage may be required in patients with renal or hepatic failure.

Barbiturates cause induction of liver enzymes so that the availability and blood levels of drugs given concurrently which are metabolised in the liver may be affected. These include the following: coumarin-type anticoagulants, systemic steroids (including oral contraceptives), phenytoin, griseofulvin, rifampicin, phenothiazines such as chlorpromazine, tricyclic antidepressants).

Side-effects: Adverse effects include drowsiness, seda-

tion, unsteadiness, vertigo and inco-ordination. Performance and alertness may be impaired during the first week of administration. Patients should be warned of the possible hazard when driving or operating machinery. These effects may be potentiated by alcohol.

Less frequent adverse reactions may include a "hangover" effect, paradoxical excitement, confusion, memory defects and skin rashes in patients who may be sensitive to this type of drug.

Accidental overdosage: Elimination of drug: Induction of vomiting, gastric lavage, and/or forced diuresis; reduce absorption of drug with activated charcoal or laxatives.

Respiratory depression: Maintenance of airway, if necessary by endotracheal intubation or tracheotomy; artificial respiration may be required. Antibiotics should be given if aspiration of vomit is suspected, or signs of bronchopneumonia are present.

Surveillance: Routine surveillance of respiration, ECG, blood pressure, body temperature, urine excretion, central venous pressure, and serum electrolytes; in severe cases, monitoring of arterial pH, pO₂, pCO₂, alkali reserve, and EEG is advised.

Pharmaceutical precautions Storage: Tablets – protect from heat and moisture.

Legal category POM.

Package quantities Tablets 200 mg: Blister packs of 100.

Further information Barbiturates have a high addiction potential. Long term use of high dosage for short periods may lead to tolerance and subsequently to physical and psychological dependence. Symptoms of dependence include confusion, defective judgement and loss of emotional control. Withdrawal symptoms occur following long-term normal use (and particularly following abuse) on rapid cessation of barbiturate treatment. Symptoms include nightmares, irritability and insomnia and, in severe cases, tremors, delirium, convulsions and death. Withdrawal symptoms have been reported in neonates following barbiturate treatment during pregnancy and labour.

Product licence number Tablets 0001/5014.

PARAZOLIDIN®

Presentation The active ingredients, Phenylbutazone BP and Paracetamol BP, are presented as: white, flat compressed tablets, approximately 13 mm diameter, scored on one side, impressed GEIGY on the other side. Containing Phenylbutazone BP 50 mg and Paracetamol BP 500 mg.

Uses Combined analgesic agent: Rheumatoid arthritis, osteoarthritis, ankylosing spondylitis, secondary carcinoma (particularly in bone) and spondylitis.

Dosage and administration Parazolidin is given orally in tablet form.

Dosage: 1 or 2 tablets two or three times a day.

Contra-indications, warnings, etc

Contra-indications: Parazolidin should not be given in the presence of: oedema or hypertension where there is a danger of cardiac decompensation. Parazolidin is also

contra-indicated in the presence of renal and hepatic disease, including recent hepatitis.

History of gastro-intestinal ulceration, blood dyscrasia, drug rash or known sensitivity to pyrazoles.

Precautions: History of dyspepsia.

Since Parazolidin may potentiate the action of coumarin-type anticoagulants by displacement from plasma protein binding, frequent estimations of prothrombin levels should be undertaken when these drugs are administered concurrently. Similarly, Parazolidin potentiates certain oral hypoglycaemic agents and sulphonamides, the dosage of which may need reducing.

It is suggested that Parazolidin be used with caution in pregnant women, weighing the potential risks against the possible benefits.

Side-effects: Gastro-intestinal intolerance or bleeding due to Parazolidin may occur.

Drug rashes, oedema, haematemesis, salivary gland swelling, goitre and jaundice due to intrahepatic cholestasis or parenchymal hepatitis have also been reported.

Blood dyscrasias (agranulocytosis, thrombocytopenia, aplastic anaemia) may occur suddenly after a small dose or insidiously after prolonged therapy, particularly in the elderly. Blood counts should be monitored regularly both before and during therapy. Therapy should be stopped if symptoms suggestive of these complications arise (e.g. bruising, fever, sore throat and rash).

Isolated occurrences of an 'acute pulmonary syndrome' – marked by dyspnoea, fever, shadows in radiographs of the lungs, and sometimes also by eosinophilia – have been reported. Although a causal relationship has not been proven, the drug should be withdrawn at first signs of this potentially serious syndrome, for the treatment of which corticosteroids and supportive cardiotherapy may be necessary.

Adverse effects of phenylbutazone therapy should always be weighed against the severity of the patient's condition and the expected clinical effect.

Accidental overdosage: Overdosage may cause hepatic necrosis. There is no specific antidote to Parazolidin, and treatment is symptomatic. Immediate treatment consists of forced emesis to recover undigested tablets. This is followed by gastric lavage.

Pharmaceutical precautions *Storage:* Protect from heat and moisture.

Legal category POM.

Package quantities *Tablets:* Containers of 100 and 500.

Further information By combining the threefold long-acting anti-inflammatory and antipyretic activity of Butazolidin with the rapid analgesic activity of Paracetamol, Parazolidin enables lower than normal doses of either substance to be administered concurrently without loss of therapeutic effect and with a reduced risk of side-effects.

Product licence number 0001/5018.

PERTOFRAN®

Presentation The active ingredient, Desipramine Hydrochloride BP, is presented as: pale apricot-pink, sugar-coated tablets, bi-convex, 5.6mm diameter and imprinted GEIGY on one side. Containing 25 mg Desipramine Hydrochloride BP in each tablet.

Uses *Antidepressant:* Symptoms of depressive illness.

Dosage and administration Pertofran is given orally in tablet form.

Adult dosage: 1 × 25 mg tablet three times a day for the first three days, increasing to 2 tablets three or four times daily. It will often be possible for the daily dose to be given as a single dose at night.

Elderly: Patients over 60 years of age may respond to lower doses of Pertofran than those recommended, usually 25 mg daily initially. The initial dose should be increased with caution under close supervision.

Children: Not established.

Contra-indications, warnings, etc

Contra-indications: Recent myocardial infarction. Any degree of heart block or other cardiac arrhythmias. Mania. Severe liver disease. Narrow angle glaucoma. Retention of urine.

Precautions: The elderly are particularly liable to experience adverse reactions, especially agitation, confusion and postural hypotension. Avoid if possible in patients with a history of epilepsy or with symptoms of bladder neck obstruction e.g. prostatic hypertrophy. Patients posing a high suicide risk require close initial supervision. Tricyclic anti-depressants potentiate the central nervous depressant action of alcohol.

Anaesthetics given during tri/tetracyclic antidepressant therapy may increase the risk of arrhythmias and hypotension. If surgery is necessary, the anaesthetist should be informed that a patient is being so treated.

As improvement in depression may not occur during the first four weeks of treatment, patients should be closely monitored during this period.

Pertofran may initially impair alertness. Patients should be warned of the possible hazard when driving or operating machinery.

Cardiac arrhythmias and severe hypotension are likely to occur with high dosage or in deliberate overdosage. They may also occur in patients with pre-existing heart disease taking normal dosage.

Do not use during pregnancy, especially during the first and last trimesters, unless there are compelling reasons. There is no evidence as to drug safety in humans; there is evidence of harmful effects in pregnancy in animals, when given in exceptionally high doses.

Nursing mothers should be advised to cease breast feeding.

Drug interactions: Pertofran should not be given concurrently with, or within 2 weeks of cessation of therapy with monoamine oxidase inhibitors.

Pertofran may decrease the antihypertensive effect of guanethidine, debrisoquine, bethanidine and possibly clonidine. It would be advisable to review all antihypertensive therapy during treatment with tricyclic antidepressants.

Pertofran should not be given with sympathomimetic agents such as adrenaline, ephedrine, isoprenaline, noradrenaline, phenylephrine and phenylpropanolamine.

Barbiturates may decrease and neuroleptics and methylphenidate may increase respectively the plasma level of tricyclic antidepressants.

Side-effects: The following adverse effects, although not necessarily all reported with Pertofran, have occurred with other tricyclic antidepressants:

Atropine-like side effects including dry mouth, disturbances of accommodation, tachycardia, constipation

and hesitancy of micturition are common early in treatment, but usually lessen.

Serious adverse effects are rare; the following have been reported: Impaired liver function and jaundice, hypomania, epileptiform convulsions. Bone marrow depression, including leucopenia, eosinophilia and thrombocytopenia. Agranulocytosis has occasionally occurred in patients receiving tricyclic antidepressants. It is advisable to perform blood counts during treatment with tri/tetracyclic antidepressants, especially if the patient develops fever, sore throat or other signs of infection.

Other possible adverse effects include drowsiness, sweating, postural hypotension, tremor and skin rashes. Interference with sexual function may occur.

Psychotic manifestations, including mania and paranoid delusion, may be exacerbated during treatment with tricyclic antidepressants.

Although not indicative of addiction, withdrawal symptoms may occur on abrupt cessation of therapy and include insomnia, irritability and excessive perspiration.

Adverse effects such as withdrawal symptoms, respiratory depression and agitation have been reported in neonates whose mothers had taken Pertofran during the last trimester of pregnancy.

Accidental overdose: Major symptoms of overdose include coma, convulsions and cardiovascular disturbances. Gastric lavage should be performed immediately and patients removed to an intensive care unit where cardiac monitoring is possible. Although there is no specific antidote, slow intravenous injection of physostigmine has yielded particularly good results in the presence of central nervous disturbances (coma, myoclonia, athetoid movements); physostigmine may possibly also exert a favourable effect on cardiac arrhythmias. The single dose, which must be individually adapted to the patient's requirements and can, if necessary, be repeated several times, is 1–4 mg for adults and 0.5 mg for children.

Pharmaceutical precautions *Storage:* Protect from moisture.

Legal category POM.

Package quantities *Tablets 25 mg:* Containers of 100 and 1,000.

Further information Nil.

Product licence number 0001/5019.

SINTHROME®

Presentation The active ingredient, Nicoumalone BP, is presented as white, compressed, scored tablets, approx. 7 mm diameter, impressed GEIGY on one side containing 4 mg in each tablet.

Pink, compressed tablets, approx. 5 mm diameter, containing 1 mg in each tablet.

Uses Oral anticoagulant. Arterial thrombosis and embolism, venous thrombosis and embolism, thrombo-phlebitis. Myocardial infarction, coronary thrombosis. For prophylaxis whenever thromboembolic complications may be anticipated and particularly in rheumatic heart disease with atrial fibrillation.

Dosage and administration Sinthrome is given orally in tablet form.

Sinthrome is available as 1 mg and 4 mg tablets and

the use of both tablets in combination enables control of oral anticoagulant therapy with a single daily dose.

Initial therapy: If the prothrombin time is within the normal range, the following daily dosage schedule is suggested:

First day	8–12 mg
Second day	4–8 mg

Maintenance therapy: Maintenance dosage of Sinthrome varies from patient to patient and must be determined on the basis of regular laboratory estimations of the clotting time of the patient's blood as determined by Quick's one-stage test – prothrombin time. The daily maintenance dosage will vary also depending upon the intensity of treatment indicated and any other drugs that the patient may be taking. In general, however, this will lie between 1 mg and 8 mg daily. In practice the upper dosage limits are seldom required and only rarely need to be exceeded, when Sinthrome is the only drug administered (see 'Precautions').

The aim of therapy is to keep the prothrombin time between the limits of a predetermined therapeutic range. As an indication of the degree of anticoagulation, the prothrombin time itself is not of much help to the practising physician unless he knows also the range of prothrombin time which reflects a satisfactory response. This range varies between different laboratories according to the sensitivity of the thromboplastin used in the test.

A uniform system of testing and reporting has been proposed and is widely used. This is based on the use of a standardised thromboplastin, the British (Manchester) Comparative Thromboplastin (BCT). The control prothrombin time for this reagent is 12 seconds and the therapeutic range for adequate anticoagulation is 22–36 seconds. The ratio of patient's prothrombin time (using the BCT) to control is termed the British Ratio (BR), the therapeutic range for which is 1.8–3.0. A patient on Sinthrome, therefore, with a British Ratio of less than 1.8 would need an increase in dosage, whilst a BR over 3.0 would require a reduction in dosage.

Not all hospitals use the BCT and in these cases control prothrombin times and therapeutic ranges will possibly differ from those referred to above. If in doubt it is best to contact the laboratory concerned.

Sometimes the result may be expressed as percentage prothrombin activity or coagulation valency. This is an indication of the prothrombin content of the patient's blood relative to a normal control of 100%. In view of the variability of thromboplastin from different sources it is difficult to give precise therapeutic ranges using this system.

However, the usually accepted therapeutic range using Quick's one-stage test, expressed as a percentage activity and using a saline dilution curve, would be 25–20% if human brain thromboplastin is used.

The administration of daily requirements of Sinthrome and the taking of blood specimens for laboratory purposes should occur at the same time of day, but not after a heavy meal or a meal rich in fats.

Withdrawal of Sinthrome entails no additional risk of thromboembolism; hence, at the end of treatment, it is not necessary to give gradually diminishing doses.

Contra-indications, warnings, etc

Contra-indications: Sinthrome is contra-indicated in all haemorrhagic conditions, including peptic ulceration and occult risks implied by severe hypertension, sub-acute bacterial endocarditis and surgical procedures.

This is absolute in operations on the central nervous system. Sinthrome is also contra-indicated in severe liver disease. Similarly in pregnancy and parturition the use of Sinthrome is contra-indicated.

Precautions: Administration with other drugs.

1. Potentiation of anticoagulant effect: Sinthrome is transported in plasma, the major proportion being as an inactive complex with plasma proteins. Many drugs will compete with Sinthrome for these protein binding sites, the consequence being displacement of Sinthrome into the plasma and an increase in anticoagulant activity. This phenomenon has been reported with such commonly used drugs as clofibrate, indomethacin, oxyphenbutazone, paracetamol and phenylbutazone. In addition to this effect, aspirin and the salicylates have a direct anticoagulant action through an effect on platelet adhesiveness. Patients taking Sinthrome who also require treatment with these or any other drugs with similar affinity for protein-binding sites may need a reduction of their anticoagulant dosage.

Administration of broad-spectrum antibiotics may decrease the requirements for Sinthrome and potentiate its effects due to interference with the synthesis of vitamin K.

2. Inhibition of anticoagulant effect. Barbiturates, chloral hydrate, glutethimide, cardiac glycosides, carbamazepine and other drugs which are metabolised in the liver may increase the metabolism of Sinthrome by stimulation of liver microsomal enzyme systems. Diuretics can reduce anticoagulant activity by altering the concentration of plasma clotting factors. During combined therapy with these drugs it is likely that anticoagulant requirements will be increased, whilst cessation of treatment will necessitate a reduction in the dosage of Sinthrome.

Intramuscular injections during anticoagulant therapy may leave haematomata. Care is also necessary when subcutaneous injection is contemplated, but intravenous injections may be given without danger.

Side-effects: Sinthrome is well tolerated and side-effects such as nausea, loss of appetite, headache or giddiness are rarely encountered. Like other anticoagulants, Sinthrome may rarely cause skin necrosis, particularly after childbirth and during the menopause.

Accidental overdosage: Where slight bleeding occurs a temporary reduction or withdrawal of Sinthrome dosage will usually result in control being re-established. Transfusions of fresh whole blood are also effective. Where these measures are inadequate to control haemorrhage, the administration of vitamin K is the best measure for treating Sinthrome overdosage. However, this should normally be reserved for serious haemorrhages since, after administration of vitamin K, the patient remains resistant to anticoagulant therapy for some time.

Pharmaceutical precautions Sinthrome is light-sensitive. Store and dispense in the original or a dark container.

Legal category POM.

Package quantities Tablets 1 mg: Containers of 500 and 200.

Tablets 4 mg: Containers of 500 and 100.

Further information *Laboratory controls:* The patient's prothrombin time should be determined before anticoagulant therapy is begun. Should the initial level be abnormal, treatment should be instituted with caution.

During the early stages of anticoagulant therapy, or when any of the patient's drugs are changed (see Precautions), daily determination of prothrombin time should be made. The frequency of laboratory evaluation can be reduced when the patient's response to Sinthrome has been established.

STEROXIN[®]-HYDROCORTISONE

Presentation The active ingredients, Chlorquinaldol and Hydrocortisone BP, are presented as: yellowish-white soft cream, in a vanishing cream base, containing chlorquinaldol 3% and Hydrocortisone BP 1%.

Uses *Antibacterial, antifungal, anti-inflammatory:* Topical treatment of eczematous, mycotic and bacterial skin conditions in adults and children.

Infantile and adult eczema, allergic eczema, varicose eczema, neurodermatitis. Contact dermatitis due to cosmetics, chemicals, including detergents, clothing materials, plant secretion, seborrhoeic dermatitis, impetigo, folliculitis, sycosis barbae, otitis externa, varicose and indolent ulcers, ano-genital pruritus.

Dosage and administration

Method of application. Steroxin-Hydrocortisone Cream should be applied to the affected area of the skin two or three times a day. If desired a light dressing may be applied for protective purposes. The cream may leave a pale yellow stain on the skin and on clothing, but this is easily removed by washing with soap.

Contra-indications, warnings, etc Steroxin-Hydrocortisone Cream is not suitable for application to the eye or to mucous membranes, where it may give rise to some irritation.

Precautions: It has been shown that corticosteroids can be absorbed by eczematous skin. Long-term administration of Steroxin-Hydrocortisone to large areas should therefore, be avoided if possible regardless of whether occlusion is used. If such administration is unavoidable precautions similar to those taken with patients receiving small doses of oral steroids should be observed.

Topical administration of corticosteroids to pregnant animals can cause abnormalities of foetal development. The relevance of this finding to human beings has not been established, however, topical steroids should not be used extensively in pregnancy, i.e. in large amounts or for prolonged periods.

In infants, long-term continuous topical therapy should be avoided. Adrenal suppression can occur even without occlusion.

Pharmaceutical precautions *Storage:* Protect from heat.

Dilutions: Diluents or other additives to this formulation are not recommended.

Legal category POM.

Package quantities Tubes of 20 g.

Further information Nil.

Product licence number 0001/5044.

SYMMETREL[®] CAPSULES

Presentation The active ingredient, amantadine hydrochloride, is presented as: brownish-red hard gelatin capsules, imprinted GEIGY in white on both cap and body, each containing 100 mg amantadine hydrochloride.

Uses Parkinson's disease. Herpes zoster. Prophylaxis and treatment of A₂, A/NJ/1/76, A/Moscow/77, A/Hong Kong/77, A/Brazil/11/78 and A/Alaska/78 influenza.

Note: *Herpes zoster:* It is recommended that the drug be given to elderly or debilitated patients in whom the physician suspects that a severe and painful rash could occur.

A₂ Influenza: It is suggested that Symmetrel be given to patients suffering from clinical influenza in whom complications might be expected to occur. In addition, Symmetrel is recommended prophylactically in cases particularly at risk, for example those with chronic respiratory disease or debilitating conditions, the elderly, those living in crowded conditions and for individuals in families where influenza has already been diagnosed, or those in essential services who are unvaccinated.

Dosage and administration *Parkinson's disease:* Initially one capsule daily for the first week, increasing to one capsule twice daily. In combination therapy, Symmetrel may be administered at these same doses. In many cases it will be possible after a few days to reduce the dosage of the other anti-Parkinson drug without loss of benefit.

Herpes zoster: Treatment should be started as soon as possible after the diagnosis has been made. The dosage is 1 capsule twice daily for 14 days. If post-herpetic pain persists after this period it is recommended that treatment be continued for a further 14 days.

Treatment of A₂ influenza: Adults: 1 capsule to be taken twice daily for five to seven days or at the discretion of the physician.

Prophylaxis of A₂ influenza: Adults: 1 capsule twice daily for as long as protection from influenza infection is required. In most instances this is expected to be for 7–10 days.

Treatment and prophylaxis in children: 10–15 years: 1 capsule every morning for the recommended period or at the discretion of the physician.

Below 10 years: As a reduced dosage is unavailable, it is not recommended that the drug be prescribed for this age group.

It is not recommended that the dosage be increased above that stated.

It may be found convenient to administer the drug at about 8 a.m. and 4 p.m.

Contra-indications, warnings, etc

Contra-indications: It is not recommended that Symmetrel be used to treat individuals who are subject to convulsions, or who have a history of gastric ulceration.

Symmetrel should not be used in patients with severe renal disease.

Although there are no specific contra-indications to the drug being administered to a person who has received a recent dose of influenza vaccine, such administration would be considered unnecessary.

Precautions: Symmetrel should be used with caution in patients with confusional or hallucinatory states.

As Symmetrel is excreted by the kidneys a cautious dosage scheme is recommended in the presence of impaired renal function. Care should be exercised when administering Symmetrel to patients with liver disease.

Patients who note central nervous system effects or blurring of vision should be advised to avoid situations where alertness is essential.

When employing Symmetrel in combination with other anti-Parkinson drugs, a watch should be kept for the latter's side-effects. Symmetrel may aggravate central nervous, gastro-intestinal or other side-effects provoked by anticholinergic drugs or L-dopa.

Although no incompatibilities with other drugs have become known, caution should be exercised if dextro-amphetamine or other central nervous stimulants are used during Symmetrel therapy.

Peripheral oedema thought to be due to an alteration in the responsiveness of peripheral vessels may occur in some patients during treatment with Symmetrel. This should be considered when the drug is prescribed for those with congestive heart failure.

Use in pregnancy: Symmetrel has not been studied in pregnant women. The use of this drug in women of child-bearing age should be undertaken only after weighing the possible risks to the foetus against benefit to the patient. Symmetrel has been reported to be embryotoxic and teratogenic in rats at 50 mg/kg/day, about 12 times the recommended human dose, but not at 37 mg/kg/day. Embryotoxic and teratogenic effects were not seen in rabbits which received up to 25 times the usual recommended adult human dose.

Side-effects: Symmetrel is well tolerated. Nevertheless, side-effects may occur in some patients. Livedo reticularis and peripheral oedema have been noted. In addition central nervous system effects such as nervousness, insomnia, dizziness and convulsions or psychic reactions such as hallucinations, or feeling of detachment have occurred. Skin rash has occurred rarely in patients sensitive to the drug.

Accidental overdose: There is no specific antidote to Symmetrel. Supportive therapeutic measures aimed at those symptoms arising from excessive central stimulation should be instituted.

Pharmaceutical precautions *Storage:* Protect from heat and light.

Legal category POM.

Package quantities *Capsules 100 mg:* Containers of 100.

Further information Symmetrel warrants serious consideration in the management of herpes zoster. This has been confirmed by a large double-blind study involving 100 patients which showed that Symmetrel can significantly reduce the proportion of patients experiencing pain of long duration.

Symmetrel has been shown to have an antiviral activity predominantly against A₂ influenza. When administered as a treatment to patients with clinical influenza, it results in a reduction of the duration of fever and symptoms of the infection. Used prophylactically, Symmetrel will provide rapid cover against influenza infection which will last for as long as therapy is continued.

The majority of studies have shown that Symmetrel does not interfere with normal antibody production.

Product licence number 0001/0006.

SYMMETREL[®] SYRUP

Presentation A clear, citrus flavoured syrup containing 50 mg/5 ml of the active ingredient amantadine hydrochloride.

Uses Parkinson's disease. Herpes zoster.

Note: *Herpes zoster:* It is recommended that the drug be given to elderly or debilitated patients in whom the physician suspects that a severe and painful rash could occur.

Dosage and administration *Parkinson's disease:* Initially 100 mg daily for the first week, increasing to 100 mg twice daily. In combination therapy, Symmetrel may be administered at these same doses. In many cases it will be possible after a few days to reduce the dosage of the other anti-Parkinson drug without loss of benefit.

Herpes zoster: The treatment should be started as soon as possible after the diagnosis has been made. The dosage is 100 mg Symmetrel twice daily for 14 days. If post-herpetic pain persists after this period it is recommended that treatment be continued for a further 14 days.

It is not recommended that the dosage be increased above that stated.

It may be found convenient to administer the drug at about 8 a.m. and 4 p.m.

Contra-indications, warnings, etc

Contra-indications: It is not recommended that Symmetrel be used to treat individuals who are subject to convulsions, or who have a history of gastric ulceration.

Symmetrel should not be used in patients with severe renal disease.

Precautions: Symmetrel should be used with caution in patients with confusional or hallucinatory states.

As Symmetrel is excreted by the kidneys a cautious dosage scheme is recommended in the presence of impaired renal function. Care should be exercised when administering Symmetrel to patients with liver disease.

Patients who note central nervous system effects or blurring of vision should be advised to avoid situations where alertness is essential.

When employing Symmetrel in combination with other anti-Parkinson drugs, a watch should be kept for the latter's side-effects. Symmetrel may aggravate central nervous, gastro-intestinal or other side-effects provoked by anticholinergic drugs or L-dopa.

Although no incompatibilities with other drugs have become known, caution should be exercised if dextroamphetamine or other central nervous stimulants are used during Symmetrel therapy.

Peripheral oedema thought to be due to an alteration in the responsiveness of peripheral vessels may occur in some patients during treatment with Symmetrel. This should be considered when the drug is prescribed for those with congestive heart failure.

Use in pregnancy: Symmetrel has not been studied in pregnant women. The use of this drug in women of child-bearing age should be undertaken only after weighing the possible risks to the foetus against benefit to the patient. Symmetrel has been reported to be embryotoxic and teratogenic in rats at 50 mg/kg/day, about 12 times the recommended human dose, but not at 37 mg/kg/day. Embryotoxic and teratogenic effects were not seen in rabbits which received up to 25 times the usual recommended adult human dose.

Side-effects: Symmetrel is well tolerated. Nevertheless,

side-effects may occur in some patients. Livedo reticularis and peripheral oedema have been noted. In addition central nervous system effects such as nervousness, insomnia, dizziness and convulsions or psychic reactions such as hallucinations, or feeling of detachment have occurred. Skin rash has occurred rarely in patients sensitive to the drug.

Accidental overdosage: There is no specific antidote to Symmetrel. Supportive therapeutic measures aimed at those symptoms arising from excessive central stimulation should be instituted.

Pharmaceutical precautions *Storage:* Protect from heat and light.

Legal category POM.

Package quantities 150 ml bottles.

Further information Symmetrel warrants serious consideration in the management of herpes zoster. This has been confirmed by a large double-blind study involving 100 patients which showed that Symmetrel can significantly reduce the proportion of patients experiencing pain of long duration.

Product licence number 0001/0067.

TANDACOTE[®]

Presentation The active ingredient Oxyphenbutazone BP is presented as: round, bi-convex, sugar-coated enteric tablets each containing 100 mg, pink in colour, of approximately 8.6 mm, and imprinted GEIGY on one side.

Uses Rheumatoid arthritis, osteoarthritis, ankylosing spondylitis and acute gout.

Osteoarthritis of the spine and degenerative disc disease presenting as lumbago, sciatica or radiculitis.

Reiter's disease and other seronegative (non-rheumatoid) arthropathies.

Inflammation associated with certain ocular diseases including uveitis, scleritis, keratitis, and postoperative inflammation.

Prevention and treatment of severe postoperative inflammation and swelling, particularly in relation to facio-maxillary, ophthalmic, laryngeal and plastic surgery.

Swelling and pain due to *serious* sprains, strains fractures and contusions.

Bursitis or synovitis associated with recognised rheumatic disorders.

Moderate to extensive superficial thrombophlebitis.

Dosage and administration Tandacote is given orally in tablet form.

Adults: For the initial 48 hours, 400–600 mg daily in divided doses with meals. Maintenance doses should be reduced to the minimum amount that will provide continuous therapeutic control, usually 200–300 mg daily.

Note: In acute gout a maximum dosage of 800 mg daily may be necessary.

Paediatric: Dosage in the range 5–10 mg per kg, with emphasis on the lower end of the scale. The small 7-year-old and younger children should be given 1 × 100 mg tablet per day.

In children of average weight between 7–12 years o

age, 2 × 100 mg tablets in divided doses per day is sufficient.

Contra-indications, warnings, etc

Contra-indications: Tandacote is contra-indicated in the presence of oedema or hypertension where there is danger of cardiac decompensation.

Tandacote is also contra-indicated in the presence of renal and hepatic disease, including recent hepatitis.

History of gastro-intestinal ulceration, blood dyscrasia, drug rash or known sensitivity to pyrazoles.

Precautions: History of dyspepsia.

Since Tandacote may potentiate the action of coumarin-type anticoagulants by displacement from plasma protein binding, frequent estimations of prothrombin levels should be undertaken when these drugs are administered concurrently. Similarly, Tandacote potentiates certain oral hypoglycaemic agents and sulphonamides, the dosage of which may need reducing.

It is suggested that Tandacote be used with caution in pregnant women, weighing the potential risks against the possible benefits.

Side-effects: Gastro-intestinal intolerance or bleeding due to Tandacote may occur.

Drug rash, oedema, haematemesis, salivary gland swelling, goitre and jaundice due to intrahepatic cholestasis or parenchymal hepatitis have also been reported.

Blood dyscrasias (agranulocytosis, thrombocytopenia, aplastic anaemia) may occur suddenly after a small dose or insidiously after prolonged therapy, particularly in the elderly. Blood counts should be monitored regularly both before and during therapy. Therapy should be stopped if symptoms suggestive of these complications arise (e.g. bruising, fever, sore throat and rash).

Isolated occurrences of an 'acute pulmonary syndrome' – marked by dyspnoea, fever, shadows in radiographs of the lungs, and sometimes also by eosinophilia – have been reported. Although a causal relationship has not been proven, the drug should be withdrawn at first signs of this potentially serious syndrome, for the treatment of which corticosteroids and supportive cardiotherapy may be necessary.

Adverse effects of oxyphenbutazone therapy should always be weighed against the severity of the patient's condition and the expected clinical effect.

Accidental overdosage: There is no antidote to Tandacote and treatment is symptomatic. Immediate treatment consists of forced emesis to recover undigested tablets. This is followed by gastric lavage.

Pharmaceutical precautions *Storage:* Protect from heat and moisture.

Legal category POM.

Package quantities *Tablets 100 mg:* Containers of 100 and 500.

Further information Tandacote is formulated as an enteric sugar-coated tablet containing a core of 100 mg Tanderil and has proved consistently reliable and therapeutically effective. Tandacote has been subjected to both single and repeated dose studies which show that Tandacote produces blood levels of the same order as Tanderil sugar-coated tablets. The satisfactory long-term usage of potent antirheumatic drugs is all too frequently a compromise between therapeutic efficacy and undesirable side-effects, particularly distressing gastro-intestinal upsets. Whilst the administration of supplementary antacids can prove helpful in these patients, formulation

research and clinical evaluation clearly demonstrates that a reliable enteric coated tablet is designed to reduce the problems of direct gastric irritation associated with most antirheumatic drugs.

Product licence number 0001/0051.

TANDALGESIC*

Presentation The active ingredients, Oxyphenbutazone BP and Paracetamol BP, are presented as: white, scored, compressed tablets approximately 14.5 mm diameter, impressed GEIGY on one side and containing Oxyphenbutazone BP 50 mg and Paracetamol BP 500 mg in each tablet.

Uses *Combined analgesic agent:* Rheumatic diseases including: rheumatoid arthritis, osteoarthritis, ankylosing spondylitis and spondylosis.

Dosage and administration Tandalgesic is given orally in tablet form.

Initially: 1 or 2 tablets three times daily, reducing to the minimum required to maintain therapeutic control.

Contra-indications, warnings, etc

Contra-indications: Tandalgesic is contra-indicated in the presence of oedema or hypertension where there is danger of cardiac decompensation.

Tandalgesic is also contra-indicated in the presence of renal and hepatic disease, including recent hepatitis.

History of gastro-intestinal ulceration, blood dyscrasia, drug rash or known sensitivity to pyrazoles.

Precautions: History of dyspepsia.

Since Tandalgesic may potentiate the action of coumarin-type anticoagulants by displacement from plasma protein binding, frequent estimations of prothrombin levels should be undertaken when these drugs are administered concurrently. Similarly, Tandalgesic potentiates certain oral hypoglycaemic agents and sulphonamides, the dosage of which may need reducing.

It is suggested that Tandalgesic be used with caution in pregnant women, weighing the potential risks against the possible benefits.

Side-effects: Gastro-intestinal intolerance or bleeding due to Tandalgesic may occur.

Drug rash, oedema, haematemesis, salivary gland swelling, goitre and jaundice due to intrahepatic cholestasis or parenchymal hepatitis have also been reported.

Blood dyscrasias (agranulocytosis, thrombocytopenia, aplastic anaemia) may occur suddenly after a small dose or insidiously after prolonged therapy, particularly in the elderly. Blood counts should be monitored regularly both before and during therapy. Therapy should be stopped if symptoms suggestive of these complications arise (e.g. bruising, fever, sore throat and rash).

Isolated occurrences of an 'acute pulmonary syndrome' – marked by dyspnoea, fever, shadows in radiographs of the lungs, and sometimes also by eosinophilia – have been reported. Although a causal relationship has not been proven, the drug should be withdrawn at first signs of this potentially serious syndrome, for the treatment of which corticosteroids and supportive cardiotherapy may be necessary.

Adverse effects of oxyphenbutazone therapy should always be weighed against the severity of the patient's condition and the expected clinical effect.

Accidental overdosage: Overdose can cause hepatic

necrosis. There is no specific antidote for Tandalgesic and treatment is symptomatic. Immediate treatment consists of forced emesis to recover undigested tablets. This is followed by gastric lavage.

Pharmaceutical precautions *Storage:* Tablets – protect from heat and moisture.

Legal category POM.

Package quantities *Tablets:* Containers of 100.

Further information During the past decade, an increasing bibliography of clinical papers has established Tanderil as a standard drug in the treatment of a wide range of painful rheumatic and traumatic inflammatory conditions.

The combination of 50 mg Tanderil and rapidly acting paracetamol 500 mg, therefore, provides an overall analgesic and antirheumatic effectiveness, and offers rapid pain relief for those patients who need more than a simple analgesic but do not yet require full doses of Tanderil.

Product licence number 0001/5025.

TANDERIL®

Presentation The active ingredient, Oxyphenbutazone BP, is presented as: coffee-coloured, sugar-coated tablets, bi-convex, approx. 8.6 mm diameter, and imprinted GEIGY on one side, containing 100 mg in each tablet.

Also cream-coloured, waxy suppositories, each containing Oxyphenbutazone BP 250 mg.

Uses Rheumatoid arthritis, osteoarthritis, ankylosing spondylitis and acute gout.

Osteoarthritis of the spine and degenerative disc disease presenting as lumbago, sciatica or radiculitis.

Reiter's disease and other seronegative (non-rheumatoid) arthropathies.

Inflammation associated with certain ocular diseases, including uveitis, scleritis, keratitis, and post-operative inflammation.

Prevention and treatment of severe postoperative inflammation and swelling, particularly in relation to facio-maxillary, ophthalmic, laryngeal and plastic surgery.

Swelling and pain due to *serious* sprains, strains, fractures and contusions.

Bursitis or synovitis associated with recognised rheumatic disorders.

Moderate to extensive superficial thrombophlebitis.

Dosage and administration Tanderil is generally given orally in tablet form but can be administered rectally by suppository.

Oral dose (adult): For the initial 48 hours, 400–600 mg daily in divided doses with meals. Patients with sensitive stomachs should be given a sodium free antacid at the same time. Maintenance doses should be reduced to the minimum amount that will provide continuous therapeutic control, usually 200–300 mg daily.

Note: In acute gout a maximum dosage of 800 mg daily may be necessary.

Rectal dosage (adult): Suppositories of Tanderil (250 mg) have been found to be a therapeutically effective alternative or supplementary dosage form.

1 or 2 Tanderil suppositories (250 mg–500 mg) daily,

as a sole therapy achieves a clinical response similar to that obtained by oral maintenance therapy.

When a suppository is required on retiring to control night pain, the total daily dosage of tablets and suppositories should not exceed 650 mg initially, with subsequent reduction to the maximum combined maintenance dose (350 mg).

Paediatric: Dosage in the range 5–10 mg/kg, with emphasis on the lower end of the scale. The small 7-year-old and younger children should be given 1 × 100 mg tablet per day, in children of average weight between 7–12 years of age, 2 × 100 mg tablets in divided doses per day is sufficient.

Contra-indications, warnings, etc

Contra-indications: Tanderil is contra-indicated in the presence of oedema or hypertension where there is danger of cardiac decompensation.

Tanderil is also contra-indicated in the presence of renal and hepatic disease, including recent hepatitis.

History of gastro-intestinal ulceration, blood dyscrasia, drug rash or known sensitivity to pyrazoles.

Precautions: History of dyspepsia.

Since Tanderil may potentiate the action of coumarin-type anticoagulants by displacement from plasma protein binding, frequent estimation of prothrombin levels should be undertaken when these drugs are administered concurrently. Tanderil also potentiates certain oral hypoglycaemic agents and sulphonamides, the dosage of which may need reducing.

It is suggested that Tanderil be used with caution in pregnant women, weighing the potential risks against the possible benefits.

Side-effects: Gastro-intestinal intolerance or bleeding due to Tanderil may occur.

Drug rash, oedema, haematemeses, salivary gland swelling, goitre and jaundice due to intrahepatic cholestasis or parenchymal hepatitis have also been reported.

Blood dyscrasias (agranulocytosis, thrombocytopenia, aplastic anaemia) may occur suddenly after a small dose or insidiously after prolonged therapy, particularly in the elderly. Blood counts should be monitored regularly both before and during therapy. Therapy should be stopped if symptoms suggestive of these complications arise (e.g. bruising, fever, sore throat and rash).

Isolated occurrences of an 'acute pulmonary syndrome' – marked by dyspnoea, fever, shadows in radiographs of the lungs, and sometimes also by eosinophilia – have been reported. Although a causal relationship has not been proven, the drug should be withdrawn at first signs of this potentially serious syndrome, for the treatment of which corticosteroids and supportive cardiotherapy may be necessary.

Adverse effects of oxyphenbutazone therapy should always be weighed against the severity of the patient's condition and the expected clinical effect.

Accidental overdose: There is no specific antidote to Tanderil and treatment is symptomatic. Immediate treatment consists of forced emesis to recover undigested tablets. This is followed by gastric lavage.

Pharmaceutical precautions *Storage:* Tablets – protect from moisture. Suppositories – protect from heat.

Legal category POM.

Package quantities *Tablets 100 mg:* Containers of 100 and 1,000.

Suppositories 250 mg: Boxes of 5 and 50.

Further information Tanderil (Oxyphenbutazone BP) is a pyrazole compound. It is a potent non-hormonal antirheumatic agent with anti-inflammatory, analgesic and antipyretic properties, of proven efficacy for the treatment of a wide range of rheumatic or traumatic inflammatory conditions.

Tablets 0001/5024
Suppositories 0001/5045

TEGRETOL®

Presentation The active ingredient, Carbamazepine BP, is presented as: 100 mg white, compressed tablets, 7 mm diameter, impressed GEIGY on one side, breakline on the other.

200 mg white, scored, compressed tablets, 9 mm diameter impressed GEIGY on one side.

400 mg white, rod shaped, flat faced tablets with bevelled edges, 17 mm long, 5.5 mm wide and 5.3 mm thick, impressed GEIGY/GEIGY on one face with breakline. Other face impressed LR with breakline.

Syrup: White, with a flavour of caramel, containing 100 mg/5ml Carbamazepine BP.

Uses *Anticonvulsant and analgesic:* Epilepsy (grand mal and temporal lobe). Trigeminal neuralgia.

Dosage and administration Tegretol is given orally in either tablet or syrup form.

Epilepsy: It is advised that a gradually increasing dosage scheme is used and this should be adjusted to suit the needs of the individual patient.

Adults: Initially: 100–200 mg once or twice a day, followed by a slow increase until the best response is obtained, often 800–1,200 mg daily. In some instances, 1,600 mg daily may be necessary.

Children: Usual dosage 10–20 mg/kg bodyweight daily in divided doses.

Age up to 1 year: 1–2 × 100 mg tablets or 5–10 ml syrup per day.

1–5 years: 2–4 × 100 mg tablets or 10–20 ml syrup per day.

5–10 years: 2–3 × 200 mg tablets or 20–30 ml syrup per day.

10–15 years: 3–5 × 200 mg tablets or 30–50 ml syrup per day.

It may be helpful to monitor the plasma concentration of Tegretol to ensure adequate therapeutic levels. In most cases the optimum therapeutic plasma level for Tegretol ranges from 3–10 mcg/ml (13–42 mc moles/l).

Trigeminal neuralgia: The individual dosage requirements of Tegretol vary considerably, depending on the age and weight of the patient. It is recommended that the initial dose be small, particularly in the frail and elderly, and that 100 mg tablets or syrup are used in the first instance.

The dose may be increased gradually until a satisfactory clinical response is obtained, which in some instances necessitates 1,600 mg Tegretol daily. It has been found that in the majority of patients a dosage of 200 mg three or four times a day is sufficient to maintain a pain-free state. It is suggested that Tegretol is taken only during acute stage of the condition and not as a prophylactic measure.

Contra-indications, warnings, etc

Contra-indications: Previous drug sensitivity to Tegretol.

Because Tegretol depresses AV-conduction, it is inadvisable to administer this drug to patients with atrioventricular conduction abnormalities unless paced.

Precautions: Use in pregnancy: If pregnancy occurs in a woman receiving Tegretol, or if the problem of initiating treatment with Tegretol arises during pregnancy, the drug's potential benefits must be carefully weighed against its possible hazards for the unborn child. This applies particularly to the first 3 months of pregnancy.

Induction of hepatic enzymes in response to Tegretol may have the effect of diminishing the activity of certain drugs that are metabolised in the liver. In patients receiving oral anticoagulant medication, it may be necessary to adjust the dosage when Tegretol is prescribed.

Tegretol may also reduce the activity of those hormones contained in the combined oral contraceptive pill. This may present clinically as breakthrough bleeding or spotting. We would recommend that patients taking Tegretol and requiring oral contraception should receive a preparation containing not less than 50 mcg of oestrogen or use some alternative non-hormonal method of contraception.

Tegretol should not be administered with, or within two weeks of cessation of MAOI therapy.

In rats treated with carbamazepine for two years, the incidence of tumours of the liver was found to be increased. There is, however, no evidence to indicate that this observation has any significant bearing on the therapeutic use of the drug.

Note: In keeping with current opinion it is suggested that the level of serum folic acid is observed during anticonvulsant therapy.

Side-effects: Dizziness may occur, but this is much less likely to be noted if the gradually increasing dosage which has been recommended is followed.

Diplopia may occur and is usually dose dependent. Drowsiness, dry mouth, diarrhoea, nausea and vomiting have also occurred amongst some patients, but these symptoms are less frequent and seldom severe.

Hyponatraemia has been reported in a few patients on higher doses of Tegretol. Similarly oedema has occasionally been noted. Both are reversible upon reduction in dosage.

A generalised erythematous rash, in some cases severe, has been reported in about 3% of patients. This has been found to disappear leaving no sequelae on stopping therapy. Isolated occurrences of exfoliative dermatitis, leucopenia, thrombocytopenia, agranulocytosis, aplastic anaemia, cholestatic jaundice and acute renal failure have been reported.

It is suggested that blood count is checked at regular intervals during the early stages of treatment.

Accidental overdosage: There is no specific antidote. Signs of overdosage include somnolence increasing to unconsciousness, hyporeflexia and convulsions. Treatment recommended:

1. Simple aspiration of gastric contents.
2. Maintenance of airway, initially by means of pharyngeal airway. If necessary, pass endotracheal tube or perform a tracheotomy.
3. Routine temperature, pulse, respiration and blood pressure readings.
4. Administration of oxygen.
5. Curarisation and artificial ventilation have been successfully employed in one case of toxic overdosage which developed convulsions.

Pharmaceutical precautions *Storage:* Syrup – Protect from heat and light, keep container tightly closed.

Dilutions: Mucilage of Tragacanth BP is suitable when used in a 1 : 1 ratio with Tegretol Syrup.

After dilution the syrup should be used within 14 days.

Legal category POM.

Package quantities *Tablets 100 mg:* Containers of 100 and 500.

Tablets 200 mg: Containers of 100 and 500.

Tablets 400 mg: Containers of 100.

Syrup 100 mg/5 ml: Bottles of 300 ml.

Further information Nil.

Syrup 100 mg/5 ml 0001/0050

TOFRANIL*

Presentation The active ingredient, Imipramine Hydrochloride BP, is presented as: red-brown, sugar-coated tablets, bi-convex, 5.6 mm diameter, imprinted GEIGY on one side, each containing 25 mg.

Red-brown, sugar-coated, triangular-shaped tablets, 5.6 mm diameter, imprinted GEIGY on one side, each containing 10 mg.

Syrup – white, with a cream flavour, containing the equivalent to 25 mg/5 ml Imipramine Hydrochloride BP.

Uses *Antidepressant/anti-enuretic:* Endogenous depression, reactive depression, involutional depression. Relief of nocturnal enuresis in children. Supplementary to chronic rheumatic pain.

Dosage and administration Tofranil is given orally in tablet or syrup form.

Adults: 1 × 25 mg three times daily for the first three days increasing to 2 × 25 mg three or four times daily. It will often be possible for the daily dose of 75 mg or 150 mg to be given as a single dose, usually at night. In hospitalised patients, or in patients under close medical supervision, it is sometimes necessary to give doses up to 225 mg or more in cases of severe depression.

Chronic rheumatic pain: 1 × 25 mg three times daily, added to the existing treatment regimen. In patients over 60 years of age, 1 × 10 mg three times daily will usually provide an adequate therapeutic effect.

Elderly: Patients over 60 years of age may respond to lower doses of Tofranil than those recommended, usually 10 mg at night initially, increasing to 10–25 mg three times daily. The initial dose should be increased with caution and under close supervision.

Children (for nocturnal enuresis only)

6–7 years (weight 20–25 kg or 44–55 lbs) 25 mg

8–11 years (weight 25–35 kg or 55–77 lbs) 25–50 mg

Over 11 years (weight 35–54 kg or 77–119 lbs) 50–75 mg

The dose should be taken just before bedtime.

To ensure lasting improvement Tofranil should be continued for six to eight weeks after which time it should gradually be withdrawn. Should a relapse occur, a further course of treatment should not be started until a full physical examination has been made.

Contra-indications, warnings, etc

Contra-indications: Recent myocardial infarction. Any degree of heart block or other cardiac arrhythmias. Mania. Severe liver disease. Narrow angle glaucoma. Infants and children under 6 years. Retention of urine.

Precautions: The elderly are particularly liable to experience adverse reactions, especially agitation, confusion and postural hypotension (see Dosage). Behavioural changes may occur in children receiving Tofranil for the treatment of nocturnal enuresis. Avoid if possible in patients with a history of epilepsy or with symptoms of bladder neck obstruction e.g. prostatic hypertrophy. Patients posing a high suicide risk require close initial supervision. Tricyclic antidepressants potentiate the central nervous depressant action of alcohol.

Anaesthetics given during tri/tetracyclic antidepressant therapy may increase the risk of arrhythmias and hypotension. If surgery is necessary, the anaesthetist should be informed that a patient is being so treated.

Care should be taken in the treatment of nursing mothers with Tofranil, since there is evidence that small amounts of imipramine may be excreted in breast milk.

As improvement in depression may not occur during the first two to four weeks treatment, patients should be closely monitored during this period.

Tofranil may initially impair alertness. Patients should be warned of the possible hazard when driving or operating machinery.

Use in pregnancy: Do not use during pregnancy especially during the first and last trimesters, unless there are compelling reasons. There is no, or inadequate evidence of safety of the drug in human pregnancy; there is evidence of harmful effects in pregnancy in animals when given in exceptionally high doses.

Drug interactions: Tofranil should not be given concurrently with, or within 2 weeks of cessation of therapy with monoamine oxidase inhibitors.

Tofranil may decrease the antihypertensive effect of guanethidine, debrisoquine, bethanidine and possibly clonidine. It would be advisable to review all antihypertensive therapy during treatment with tricyclic antidepressants.

Tofranil should not be given with sympathomimetic agents such as adrenaline, ephedrine, isoprenaline, noradrenaline, phenylephrine and phenylpropanolamine.

Barbiturates may decrease and methylphenidate and neuroleptics may increase respectively the plasma level of Tofranil.

Side-effects: Atropine-like side-effects including dry mouth, disturbances of accommodation, tachycardia, constipation and hesitancy of micturition are common early in treatment, but usually lessen.

Other possible adverse effects include drowsiness, sweating, postural hypotension, tremor and skin rashes. Interference with sexual function may occur.

Serious adverse effects are rare; the following have been reported: Impaired liver function and jaundice, hypomania, epileptiform convulsions. Bone marrow depression, including leucopenia, eosinophilia and thrombocytopenia. Agranulocytosis has occasionally occurred in patients receiving tricyclic antidepressants. It is advisable to perform blood counts during treatment with tri/tetracyclic antidepressants, especially if the patient develops fever, sore throat or other signs of infection.

Cardiac arrhythmias and severe hypotension are likely to occur with high dosage or in deliberate overdosage.

They may also occur in patients with pre-existing heart disease taking normal dosage.

Psychotic manifestations, including mania and paranoid delusion, may be exacerbated during treatment with tricyclic antidepressants.

Although not indicative of addiction, withdrawal symptoms may occur on abrupt cessation of therapy and include insomnia, irritability and excessive perspiration.

Adverse effects such as withdrawal symptoms, respiratory depression and agitation have been reported in neonates whose mothers had taken Tofranil during the last trimester of pregnancy.

Accidental overdosage: Major symptoms of overdosage include coma, convulsions and cardiovascular disturbances. Gastric lavage should be performed immediately and patients removed to an intensive care unit where cardiac monitoring is possible. Treatment is symptomatic. Although there is no specific antidote, slow intravenous injection of physostigmine has yielded particularly good results in the presence of central nervous disturbances (coma, myoclonia, athetoid movements); physostigmine may possibly also exert a favourable effect on cardiac arrhythmias. The single dose, which must be adapted to the patient's requirements and can, if necessary, be repeated several times, is 1–4 mg for adults and 0.5 mg for children.

Pharmaceutical precautions *Storage:* Syrup – protect from heat; keep containers tightly closed. Tablets – protect from moisture.

Dilutions: Syrup – for dilutions down to 15 mg/5 ml, boiled distilled or de-ionised water can be used. For dilutions below 15 mg/5 ml, the recommended diluent is equal parts simple Syrup BP and freshly prepared Mucilage of Tragacanth BP. After dilution the solution should be used within a few days.

Legal category POM.

Package quantities *Tablets 25 mg:* Blister packs of 100.

Tablets 10 mg: Blister packs of 100.

Syrup 25 mg/5 ml: Bottles of 150 ml.

Further information Nil.

VOLTAROL®

Presentation Tablets containing 25 mg diclofenac sodium, circular, slightly biconvex with bevelled edges, yellow enteric-coated, approximately 7 mm diameter, imprinted GEIGY on one side.

Tablets containing 50 mg diclofenac sodium, circular, slightly biconvex with bevelled edges, light brown enteric coated, approximately 8 mm diameter, imprinted GEIGY on one side.

Suppositories containing 100 mg diclofenac sodium in a waxy base, yellowish-white, torpedo shaped, weighing approximately 2.00 g.

Ampoules of clear glass containing 75 mg/3 ml diclofenac sodium.

Uses *Tablets and suppositories:* Rheumatoid arthritis; osteoarthritis; low back pain and other acute musculo-skeletal disorders such as periarthritis (especially frozen shoulder), tendinitis; tenosynovitis, bursitis, sprains,

strains and dislocations; ankylosing spondylitis; acute gout; control of pain and inflammation in orthopaedic, dental and other minor surgery.

Ampoules: Acute exacerbation of rheumatoid arthritis and osteoarthritis; acute back pain; acute gout; post operative pain.

Mode of action: Voltarol is a non-steroidal agent with marked analgesic/anti-inflammatory and antipyretic properties.

Dosage and administration *Tablets:* A total of 75–150 mg daily given in two or three divided doses.

Suppositories: One suppository daily, usually administered at night. In more severe cases, combined therapy with tablets is recommended. The daily dose should not exceed 150 mg.

Ampoules: 1 × 75 mg ampoule once or twice daily intramuscularly by deep intragluteal injection into the upper outer quadrant. Following a satisfactory response to intramuscular injection, changeover to oral therapy may be initiated. Voltarol should *not* be administered by intravenous injection.

Dosage in children has not yet been established.

Contra-indications, warnings, etc *Side-effects:* Initially, some patients may complain of epigastric pain, nausea and diarrhoea, headache and slight dizziness. These side-effects are often transient, disappearing with continuation of medication.

Occasionally skin rash, peripheral oedema and abnormalities of serum transaminases have been reported.

Very rarely peptic ulcer and haematemesis or melaena have been reported, mainly in patients with a history of such disorders, or who were receiving concomitant antirheumatic medication.

Suppository: local reactions include itching, burning and increased frequency of bowel movement.

Ampoule: local reactions may include pain or a burning sensation.

Precautions: Voltarol should not be prescribed during pregnancy, unless there are compelling reasons for doing so.

Patients with a history of peptic ulcer, haematemesis or melaena, or bleeding diathesis or with severe hepatic or renal insufficiency, should be kept under close surveillance.

Voltarol has been reported to depress salicylate levels and vice versa; the clinical relevance of this phenomenon is not yet clear.

Voltarol suppositories should be used only with caution in patients with painful or irritable ano-rectal conditions.

Contra-indications: Peptic ulcer.

Voltarol is contra-indicated in asthmatic patients in whom attacks of asthma, urticaria or acute rhinitis are precipitated by aspirin or other non-steroidal anti-inflammatory agents with prostaglandin synthetase inhibiting activity.

Treatment of overdosage: There is no known antidote to Voltarol and the treatment is symptomatic. Immediate treatment consists of forced emesis to recover undigested tablets.

Pharmaceutical precautions *Storage:* Tablets – protect from heat and moisture.

Suppositories – protect from heat.

Ampoules – protect from heat and light.

Legal category POM.

Package quantities *Tablets:* Packs of 100.

Suppositories: Packs of 10.

Ampoules: packs of 10.

Further information Pharmacodynamic studies have shown no potentiation of oral hypoglycaemic and anticoagulant drugs.

AMINOPLEX* 5

Presentation A solution of synthetic L-form amino acids in combination with calorie supplement. Sterile and pyrogen-free.

Active ingredients per litre: Synthetic-L-form amino acids:

L-Isoleucine	1.53 g
L-Leucine	2.33 g
L-Lysine HCl	2.74 g*
L-Methionine	1.93 g
L-Phenylalanine	2.77 g
L-Threonine	1.29 g
L-Tryptophan	0.56 g
L-Valine	1.80 g
L-Arginine	3.70 g
L-Histidine	0.89 g
L-Alanine	4.03 g
L-Glutamic acid	0.80 g
Glycine	1.77 g
L-Proline	4.83 g
L-Ornithine-L-Aspartate	0.80 g
L-Serine	0.97 g

*2.19 g as free base.

Calorie source:

Sorbitol	125 g
Ethanol	50 g

Electrolytes:

Sodium	35 mmol
Potassium	28 mmol
Magnesium	4 mmol
Chloride	43 mmol
Acetate	28 mmol

Additional nutrients:

L-Malic acid	1.85 g
--------------	--------

Providing: 5 g/l of utilisable nitrogen, 4.2 MJ (1000 kcal). Total energy content, 3.6 MJ (868 kcal) non-nitrogen energy content.

Hypertonic solution pH 7.4 ± 0.2

Osmolality approximately 2415 mosmol/kg.

Uses For intravenous feeding, providing in a utilisable form, basic body requirements for amino acids, calories and certain electrolytes in one solution. This provides a simple regime for short-term total intravenous feeding, or alternatively a basis for more complex nutritional programmes tailored to specific clinical requirements.

Indications are clinical situations when oral feeding is impossible or contra-indicated. Alternatively Aminoplex 5 infusion would be appropriate pre- or post-operatively or in gastro-intestinal disturbances such as malabsorptive states, where adequate nutrition cannot be achieved orally.

Dosage and administration *Adult Dose (70 kg bodyweight):* 1000–3000 ml in 24 hours by central intravenous injection.

Infusion Rate: Maximum 40ml/kg/day.

Children's dosage at physicians' discretion.

Infusion rate should be tailored to patient body weight and should be commenced slowly at 20 ml/kg/day on the first day. For the second day and thereafter the infusion rate may be increased to a maximum of 40 ml/kg/day; the aim should be to maintain a constant infusion rate over the full 24 hours of each day.

Utilisable nitrogen is provided as synthetic L-form amino acids, 1 g of nitrogen being administered with each 175 non-nitrogen kcal. In cases with greatly increased requirements, e.g. sepsis or complications of surgery where glucose may be a more appropriate energy source, patients may benefit from an alternative regimen of Aminoplex 12 plus GluCoPLEX (with or without insulin).

Contra-indications, warnings, etc Before commencing infusion with Aminoplex 5, it is important to exclude conditions which may promote the risk of acidosis; for this reason, certain patient selection criteria should be applied during regimen planning – these are:–

- Adequate circulating volume.
- Adequate liver function.
- Adequate renal function.
- Absence of acidosis or hypoxaemia.

Patients not conforming to these criteria may have elevated lactate levels; for patients in this category or where the requirement for nitrogen and calories cannot be met within the maximum recommended infusion rate of 40 ml/kg/day, a regimen of Aminoplex 12 and GluCoPLEX will be more appropriate.

Depending on the patients clinical state and electrolyte balance, there may be a need for supplementary electrolyte replacement based on biochemical monitoring. Routine supplementation with vitamins and trace elements should also be undertaken as and when necessary. Of special importance is folic acid as amino acid mixtures may precipitate acute folate deficiency; accordingly folic acid should be given daily together with B vitamins. As Aminoplex 5 contains ethanol and sorbitol, care should be taken when considering the administration of drugs which interfere with their pathways of metabolism.

Pharmaceutical precautions Check that the solution is clear, and the container undamaged. Discard if not fully used at one injection.

Store below 25°C.

Keep away from light.

Data on compatibility and levels of permissible additions of vitamins and trace elements are available from the manufacturers.

The addition of drugs to amino acid solutions should be avoided.

Legal category POM.

Package quantities Glass bottles of 1000 ml.

Further information Due to optical sensitivity of the ingredients, some colour variation of the solution may be anticipated.

Product licence number 0184/0036.

AMINOPLEX* 12

Presentation A concentrated solution of synthetic L-form amino acids. Sterile and pyrogen-free.

Active ingredients per litre: Synthetic L-form amino acids:

L-Isoleucine	3.80 g
L-Leucine	5.80 g
L-Lysine HCl*	6.80 g
L-Methionine	4.80 g
L-Phenylalanine	6.88 g
L-Threonine	3.20 g
L-Tryptophan	1.40 g
L-Valine	4.48 g
L-Arginine	9.20 g
L-Histidine	2.20 g
L-Alanine	10.00 g
L-Glutamic acid	2.00 g
Glycine	4.40 g
L-Proline	12.00 g
L-Ornithine-L-Aspartate	2.00 g
L-Serine	2.40 g
(*5.44 g as base)	

Electrolytes:

Sodium	35 mmol
Potassium	30 mmol
Magnesium	2.5 mmol
Chloride	67 mmol
Acetate	5 mmol

Additional nutrients: L-Malic acid 4.6 g.

Providing: 12.44 g/l of utilisable nitrogen. Total energy content 315 kcal (1.3MJ).

Hypertonic solution pH 7.4 ± 0.2

Osmolality approximately 830 mosmol/kg.

Uses A synthetic L-form amino acid and electrolyte mixture for intravenous administration in intravenous feeding when a high level intake of protein amino acids is required in low fluid volume and also situations where flexibility of choice of calorific substrate is preferred.

In cases with greatly increased requirements, eg. sepsis or complications of surgery and trauma, glucose is considered the appropriate energy source, and patients may benefit from a regimen of Aminoplex 12 plus GluCoPLEX (with or without insulin). Administration of Aminoplex 12 should always be accompanied by concurrent administration of a suitable energy source, for example, GluCoPLEX.

Dosage and administration *Adult Dose (70 kg bodyweight):* 500–2000 ml in 24 hours by central intravenous injection.

Infusion Rate: Maximum 40–50 drops per minute.

Children's dosage at physicians' discretion.

Contra-indications, warnings, etc Aminoplex 12 is contra-indicated in irreversible liver damage.

Moderate liver damage and uraemic states where facilities for dialysis exist are not contra-indications for the use of Aminoplex 12.

Amino acid mixtures may precipitate acute folate deficiency and folic acid should be given daily. Vitamin

B₁₂ status should be checked and prophylaxis given if necessary.

Pharmaceutical precautions Check that the solution is clear, and the container undamaged. Discard if not fully used at one injection.

Store below 25°C.

Keep away from light.

Data on compatibility and levels of permissible additions of vitamins and trace elements are available from the manufacturers.

The addition of drugs to amino acid solutions should be avoided.

Legal category POM.

Package quantities Glass bottles of 500 ml and 1000 ml.

Further information Due to optical sensitivity of the ingredients, some colour variation of the solution may be anticipated.

Product licence number 0184/0030.

AMINOPLEX* 14

Presentation A concentrated solution of synthetic L-form amino acids. Sterile and pyrogen-free.

Active ingredients per litre: Synthetic L-form amino acids:

L-Isoleucine	3.20 g
L-Leucine	4.40 g
L-Lysine HCl	8.49 g
L-Methionine	6.40 g
L-Phenylalanine	4.40 g
L-Threonine	3.20 g
L-Tryptophan	1.60 g
L-Valine	5.20 g
L-Arginine	9.20 g
L-Histidine	2.80 g
L-Alanine	14.80 g
Glycine	12.00 g
L-Proline	4.00 g
L-Ornithine-L-Aspartate	2.00 g

Electrolytes:

Sodium	35 mmol
Potassium	30 mmol
Chloride	79 mmol

Additional nutrients:

Vitamin B ₆ HCl	0.03 g
Nicotinamide	0.05 g
L-Malic acid	5.36 g

Providing: 13.4 g/l of utilisable nitrogen. Total energy content 340 kcal (1.4MJ).

Hypertonic solution pH 7.4 ± 0.2

Osmolality approximately 875 mosmol/kg.

Uses A synthetic L-form amino acid and electrolyte mixture for intravenous administration in intravenous feeding when a high level intake of protein amino acids is required in low fluid volume and also situations where flexibility of choice of calorific substrate is preferred.

In cases with greatly increased requirements, eg. sepsis or complications of surgery and trauma, glucose is considered the appropriate energy source, and patients may benefit from a regimen of Aminoplex 14 plus GluCoPLEX (with or without insulin). Administration of Aminoplex 14 should always be accompanied by

concurrent administration of a suitable energy source, for example, GluComplex.

Dosage and administration *Adult Dose (70 kg bodyweight):* 500–2000 ml in 24 hours by central intravenous injection.

Infusion Rate: Maximum 40–50 drops per minute. Children's dosage at physicians' discretion.

Contra-indications, warnings, etc Aminoplex 14 is contra-indicated in irreversible liver damage.

Moderate liver damage and uraemic states where facilities exist for dialysis are not contra-indications for the use of Aminoplex 14. Amino acid mixtures may precipitate acute folate deficiency and folic acid should be given daily. Vitamin B₁₂ status should be checked and prophylaxis given if necessary.

Pharmaceutical precautions Check that solution is clear. Discard if not fully used at one injection.

Store below 25°C.

Keep away from light.

The addition of drugs to amino-acid solutions should be avoided.

Legal category POM.

Package quantities Glass bottles of 500 ml, 10 bottles per box.

Further information Due to optical sensitivity of the ingredients some colour variation of the solution may be anticipated.

Product licence number 0184/5002.

AMINUTRIN*

Presentation A pale yellow powder with a slight odour. Contains amino acids.

Active ingredients %: Typical Analysis per 100 g.

L-Isoleucine	5.00 g
L-Leucine	9.00 g
L-Lysine	8.20 g
L-Methionine	4.30 g
L-Phenylalanine	7.30 g
L-Threonine	3.80 g
L-Tryptophan	1.40 g
L-Valine	5.90 g
L-Arginine	0.90 g
L-Histidine	2.40 g
L-Alanine	3.30 g
L-Glutamic acid	23.10 g
Glycine	1.90 g
L-Proline	12.00 g
L-Aspartic acid	6.60 g
L-Serine	4.60 g
L-Tyrosine	0.30 g

One 15 g sachet of Aminutrin provides 1.8 g of available Nitrogen equivalent to 11.7 g Protein.

Uses Aminutrin is used to provide the protein basis of a diet in order to maintain a good state of nutrition for patients who are unable or unwilling to take conventional diets. When used with a suitable calorie source (e.g. Calonutrin), Aminutrin is ideal for tube-feeding.

Clinical indications being—trauma, burns, unconscious patients, anorexia nervosa, impaired mastication due to maxillo-facial injury, Crohn's disease, ulcerative

colitis, diverticulitis, malabsorption syndromes (i.e. coeliac disease, sprue, genetic disorders, intestinal malfunction), nutritional provision in pre- or post-surgery, low bulk feeding in patients where intestinal surgery is a factor, and where preparation for X-ray is imminent, short bowel syndrome and intestinal fistulae, Geriatrics – inability to take a normal diet.

Dosage and administration 30–75 g per day (two to five 15 g sachets). This product is a protein-based food and upper restriction on intake is therefore inappropriate. Aminutrin should be given with the correct quantity of carbohydrate calories (Calonutrin) for maximum utilisation. As a guide the calorie to nitrogen ratio should be about 200:1 kcal/g (or 15 g Aminutrin to 100 g Calonutrin).

Tube and oral feeding: For oral feeding Aminutrin is best given as an addition to consommé beef soup, 1 sachet per portion. Other recipes for oral use are contained in a recipe book obtainable from the manufacturers.

Contra-indications, warnings, etc With all tube feeding regimes, careful attention must be paid to fluid and electrolyte balance as these may need to be corrected. Vitamin supplements will be required, and will depend on the needs of the patient.

Not for parenteral administration.

Accidental Overdosage: No instance of adverse reaction to an overdosage of Aminutrin has been recorded and no specific measures are indicated.

Pharmaceutical precautions Solutions of Aminutrin should not be boiled. Store below 25°C.

Legal category GSL.

Package quantities 10 × 15 g vacuum-sealed sachets in each carton. A package insert leaflet is included, with instructions and suggested diet regimes.

Further information Nil.

Product licence number 0184/0026.

ANAFLEX* AEROSOL

Presentation Antibacterial and antifungal spray containing Polynoxylin 2% for the control of localised infection by external application.

Uses Anaflex Aerosol is indicated for the treatment of athlete's foot, nappy rash, pressure sores, pruritus ani, pruritus vulvae, boils, infective dermatitis, intertrigo, minor wounds.

It is of benefit for colostomy and ileostomy control and for general use in casualty.

Dosage and administration Apply freely to the site of infection or of potential infection.

Contra-indications, warnings, etc For external application only. Caution when spraying near the eyes. Not for intubation nor inhalation.

Pharmaceutical precautions The aerosol can should be stored away from direct heat. The container should not be punctured or destroyed by burning, even when empty.

Legal category P.

Package quantities Aerosol canisters of 100 g.

Further information Contains talc.

Product licence number 0184/5008.

ANAFLEX* CREAM

Presentation A smooth white water-miscible cream with a pleasant odour containing 10% Polynoxylin.

Uses An antibacterial and antifungal preparation for use in a wide variety of dermatological conditions including athlete's foot, nappy rash, pressure sores, boils, stasis ulcers, pruritus ani, pruritus vulvae.

The product has proved of value in promoting wound healing and for the control of tissue reaction following radiotherapy.

Anaflex Cream is indicated also for the treatment of a wide range of aural and nasal infections including otitis externa.

Dosage and administration By application to the affected site once or twice daily.

For the treatment of infected ears the cream should be applied daily by means of a $\frac{1}{2}$ -inch ribbon gauze wick.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store below 25°C.

Legal category P.

Package quantities Tubes of 50 g.

Further information Anaflex cream may be used in conjunction with Anaflex Paste in the treatment of stasis ulcers.

Product licence number 0184/5006.

ANAFLEX* LOZENGES

Presentation Flat, white, circular lozenges with a bevelled edge and embossed 'GEISTLICH' on each face. Each lozenge contains 30 mg Polynoxylin in a citrus-flavoured base.

Uses An antibacterial, antifungal preparation having an anti-inflammatory action and ideally suited for the treatment of mouth and throat infections in tonsillitis, oral thrush, mouth ulcers.

Dosage and administration In most conditions 6–10 lozenges per day will be found suitable. Minor throat infections usually respond in two to three days. More difficult infections (eg Candida) will take longer to respond and treatment can be continued if necessary for four to six weeks.

The lozenges do not contain local anaesthetic and sensitisation will not occur when given over a period of time.

Contra-indications, warnings, etc *Accidental overdose:* No instance of adverse reaction to an overdose of Anaflex Lozenges has been recorded and no specific measures are indicated.

Pharmaceutical precautions Store below 25°C.

Legal category P.

Package quantities Containers of 50 lozenges.

Further information Nil.

Product licence number 0184/5007.

ANAFLEX* PASTE

Presentation A smooth white paste containing Polynoxylin 10%.

Uses Anaflex Paste is beneficial for the control of external infections of bacterial and fungal origin in body areas where moisture is present.

It is indicated for use in athlete's foot, nappy rash, intertrigo, colostomy and ileostomy control, infective dermatitis, boils and stasis ulcers.

Dosage and administration Application to the area for treatment once or twice daily.

Colostomy and ileostomy control: Anaflex Paste gently massaged into the surrounding area will control and effectively treat excoriated tissue present. It will be noted that a colostomy bag will adhere to a surface treated with Anaflex Paste.

Stasis ulcers: Anaflex Cream may be applied direct to the ulcer. Any surrounding eczema will benefit by the application of Anaflex Paste.

Contra-indications, warnings, etc Nil.

Pharmaceutical precautions Store below 25°C.

Legal category P.

Package quantities Tubes of 20 g.

Further information Anaflex Paste may be used in conjunction with Anaflex Cream in the treatment of stasis ulcers.

Product licence number 0184/5005.

ANAFLEX* POWDER

Presentation A white powder with antibacterial, antifungal and anti-inflammatory properties containing Polynoxylin 10%.

Uses For the control of infection on the body surface including athlete's foot, nappy rash, pressure sores, minor wounds, stasis ulcers and in casualty.

Anaflex Powder is indicated also for the treatment of a wide range of aural and nasal infections including otitis externa.

Dosage and administration Apply freely to infected area or area of potential infection by means of the sprinkler pack.

Contra-indications, warnings, etc For external application only. Exclude perforated ear drum.

Pharmaceutical precautions Store below 25°C.

Legal category P.

Package quantities Sprinkler pack of 30 g.

Further information Contains talc.

Product licence number 0184/5003.

CALONUTRIN*

Presentation White, odourless, free-flowing powder containing glucose, maltose and polysaccharides.

Each 100 g sachet provides 1.72 MJ (410 kcal)

Uses Generally in any condition where calories are needed and high tolerance is essential in tube and oral feeding.

Clinical indications being—nutrition in pre- and post-surgical situations, burns, coma, coeliac disease, sprue, Crohn's disease, etc. ulcerative colitis, cystic fibrosis, renal failure (uraemia), hepatic failure, cirrhosis of the liver, anorexia nervosa, dysphagia and geriatric malnutrition, hypoglycaemia, convalescence, intolerance conditions, i.e. fat and lactose intolerance.

Dosage and administration Because Calnutrin provides calories alone it should be given in conjunction with a protein/amino acid tube or oral food, such as Aminutrin.

Exact methods of use of the combined diet will be found in every pack of Aminutrin.

In cases where extra calories are required Calnutrin may be given as a drink using one part Calnutrin to three parts fluid (1 sachet 100 g Calnutrin to 300 ml fluid) in fruit drinks, tea, coffee or milk. It may, in place of sugar, also be used in cooking, to prepare cakes, pastry, etc.

Contra-indications, warnings, etc When used in the diabetic the usual precautions for carbohydrate intake must be considered. Not for parenteral administration.

Pharmaceutical precautions Store below 25°C protected from moisture.

Legal category GSL.

Package quantities Boxes of 10 sachets of 100 g.

Further information The electrolyte content is low; each 100 g of Calnutrin containing: Sodium 4 mmol, Potassium 0.3 mmol.

Product licence number 0184/0025.

GLUCOPLEX* 1000

Presentation A clear solution of 24% glucose premixed with electrolytes and trace elements. Sterile and pyrogen-free.

Active ingredients per litre:

Sodium	50.0 mmol
Potassium	30.0 mmol
Magnesium	2.5 mmol
Zinc	45.6 mcmol
Dihydrogen phosphate	18.0 mmol
Chloride	67.0 mmol
Anhydrous glucose	240.0 g

Providing: 4.2 MJ (1000 kcal) per litre.

Hypertonic solution

Osmolality approximately 1750 mosmol/kg.

Uses A solution of glucose calories, electrolytes and trace elements for use in intravenous feeding; it is intended for use in combination with a nitrogen source, for example, Aminoplex 12.

Dosage and administration *Adult Dose* (70 kg bodyweight): 1000–3000 ml in 24 hours by intravenous injection.

Infusion Rate: maximum 50 drops per minute.

Children's dosage at physicians' discretion.

Contra-indications, warnings, etc Special precautions to be taken in diabetes mellitus, diabetes insipidus, hyperosmotic coma, hyperkalaemia, untreated shock, renal failure, water intoxication and patients with glucose/galactose malabsorption syndrome.

Hypertonic glucose may induce thrombophlebitis especially when infused into peripheral veins. Rapid infusion may invoke hyperglycaemia, hyperosmolar states, osmotic diuresis and resultant dehydration if used in inappropriately high doses or in patients with impaired glucose metabolism. Because Glucoplex contains potassium, hyperkalaemia may be exacerbated or induced on rapid infusion. If glucose solutions are given at a rate which exceeds their metabolism a hyper-osmolar condition with a rising serum sodium may occur. In such cases there may be hypernatraemia and a rise in the MCV which must be differentiated from iatrogenic sodium overload. Alternatively the respiratory quotient (RQ) may rise above one giving a high CO₂ production. These complications are more common in severely ill patients. The appropriate glucose load for the patient may be judged from patient clinical state, biochemical response to glucose or by assessment of resting metabolic expenditure.

Pharmaceutical precautions Check that the solution is clear and the container undamaged. Discard if not fully used at one injection. Store below 25°C. Keep away from light.

Data on compatibility and levels of permissible additions of vitamins and trace elements are available from the manufacturers.

Legal category POM.

Package quantities Clear glass bottles of 500 ml and 1000 ml.

Further information Nil.

Product licence number 0184/0032.

GLUCOPLEX* 1600

Presentation A clear solution of 40% glucose premixed with electrolytes and trace elements. Sterile and pyrogen-free.

Active ingredients per litre:

Sodium	50.0 mmol
Potassium	30.0 mmol
Magnesium	2.5 mmol
Zinc	45.6 mcmol
Dihydrogen phosphate	18.0 mmol
Chloride	67.0 mmol
Anhydrous glucose	400.0 g

Providing: 6.72 MJ (1600 kcal) per litre.

Hypertonic solution

Osmolality approximately 2900 mosmol/kg.

Uses A solution of glucose calories, electrolytes and trace elements for use in intravenous feeding; it is intended for use in combination with a suitable nitrogen source, for example, Aminoplex 12.

Dosage and administration *Adult Dose* (70 kg bodyweight) 1000–3000 ml in 24 hours by intravenous injection.

Infusion Rate: maximum 50 drops per minute.

Children's dosage at physicians' discretion.

Contra-indications, warnings, etc Special precautions to be taken in diabetes mellitus, diabetes insipidus, hyperosmotic coma, hyperkalaemia, untreated shock, renal failure, water intoxication and patients with glucose/galactose malabsorption syndrome.

KAY-CEE-L* SYRUP

Presentation A clear red cherry flavoured sugar-free syrup containing Potassium Chloride BP 7.50% w/v providing Potassium – 1 mmol per ml.

Uses Indicated in all situations where oral potassium supplementation is required. Typical examples—diuretic therapy, Cushing's syndrome, megaloblastic anaemia, diabetic ketosis; during intensive steroid, corticotrophin and carbenoxolone therapy. Primary aldosteronism, metabolic alkalosis.

Dosage and administration *Adults:* 10–50 ml per day at clinician's discretion.

Children: At clinician's discretion.

Doses should be given in divided amounts, after food.

Contra-indications, warnings, etc Impaired renal function, dehydration, and hyperkalaemia.

High doses taken inadvertently will act as an emetic.

Pharmaceutical precautions Store below 25°C.

Legal category P.

Package quantities Bottles of 500 ml.

Further information Potassium chloride in an oral syrup form has recently been cited as potentially more effective than tablets because of its rapid absorption from the stomach. The syrup is also without risk of causing small bowel haemorrhage, ulceration, and stricture formation. It is important to recognise the use of the chloride salt of potassium, due to the effect of the chloride moiety in controlling metabolic alkalosis. Contains Sorbitol.

Product licence number 0184/0031.

LAEVUFLEX* 20

Presentation A colourless solution containing laevulose. Sterile and pyrogen free.

Active ingredients per litre:

Laevulose BP 200 g

Providing: 3.4 MJ (820 kcal)

Hypertonic solution

Osmolality approximately 1330 mosmol/kg

Uses As a calorie source for parenteral administration.

Dosage and administration *Adult Dose* (70 kg bodyweight) 500–2000 ml in 24 hours by intravenous injection.

Infusion Rate: Maximum 50 drops per minute.

Children's dosage at physicians' discretion.

Contra-indications, warnings, etc Administration to patients with familial laevulose intolerance may result in hypoglycaemia.

Before commencing infusion with Laevuflex 20, it is important to exclude conditions which may promote the risk of acidosis; for this reason, certain patient selection criteria should be applied during regimen planning – these are:–

- Adequate circulation volume.
- Absence of impaired liver function.
- Adequate renal function.
- Absence of acidosis.
- Adequate pulmonary function.

If the patient does not fulfil these selection criteria, a regimen based on a glucose calorie source, for instance GlucoPlex, will be more appropriate.

Pharmaceutical precautions Store below 25°C. Keep away from light. Check solution is clear: discard if not fully used at one injection.

Legal category POM.

Package quantities Glass bottles of 500 ml, 10 bottles per box.

Further information Nil.

Product licence number 0184/5001.

NOXYFLEX* 'S'

Presentation A white crystalline powder containing 2.5 g Noxythiolin.

Uses Noxythiolin has a wide spectrum of antifungal and antibacterial activity for the prevention and eradication of infection from the body surface and specified accessible cavities. Intraperitoneally, it is an effective anti-endotoxin and anti-adhesion agent.

Dosage and administration The solution is most commonly used at concentrations of 1, 2.5 and occasionally 5%. For prophylactic use a 1% solution is frequently employed; for therapeutic use a 2.5% solution is normally administered.

Ensure contact of the solution on the body surface or in specified cavities for at least 30 minutes. The period of treatment should not normally extend beyond 72 hours, or five days where otherwise stated above.

Gynaecology: Intermittent catheterisation: Use 100 ml of 1% solution at each catheterisation as prophylaxis; for treatment, use a 2.5% solution.

Indwelling catheters: Use 100 ml of 1% solution twice daily as prophylaxis; for treatment, use a 2.5% solution.

Urology and surgery: Catheterisation: 100 ml of 1% solution once or twice daily as prophylaxis. 100 ml of 2.5% solution once or twice daily as a treatment.

Peritonitis: 100 ml of a 2.5% Solution instilled into the peritoneum before closure.

Empyema: 100 ml of a 1% Solution daily for a minimum of five days, leaving the intercostal drain clamped for a period of 30 minutes.

Infected wounds and fistulae: Irrigate with a 1% Solution twice daily for five days.

Burns: 1% Solution as a wet dressing twice daily.

Abscess cavities: 2.5% Solution administered via polythene tube, twice daily for five days.

Radiotherapy (Ca Bladder): 50 ml of 2.5% Solution administered via catheter during planning.

Contra-indications, warnings, etc Noxyflex 'S' can be used concurrently with the administration of systemic drugs. The use of Noxyflex 'S' in conjunction with other pharmaceutical agents for combined irrigation/instillation therapy is not recommended and solution preparation should be carried out as stated under 'Pharmaceutical preparation'. The normal daily usage of Noxyflex 'S' in adults should not exceed 10 g for either accumulative (ie. repeated) instillation regimens or continuous irrigation regimens. Solutions are not intended for intravenous use.

Pharmaceutical precautions *Storage of powder:* The powder vials should be kept in a cool place.

Storage of Solution: Solution should be kept at 2–10°C and used within 7 days. Containers of prepared solution are intended for single use only.

Solution Preparation: The powder should be dissolved completely in a sufficient quantity of Water for Injections BP or Sodium Chloride Intravenous Infusion BP (0.9 per cent w/v) by an aseptic technique. Slight difficulty may be experienced in preparing solutions.

To make a 2.5% solution: Add contents of one vial (2.5 g) to 100 ml of Water for Injections BP or Sodium Chloride Intravenous Infusion BP (0.9 per cent w/v) and shake for a half to two minutes. **Do not heat.**

To make a 1% solution: Add contents of one vial (2.5 g) to 250 ml of Water for Injections BP or Sodium Chloride Intravenous Infusion BP (0.9 per cent w/v) and shake for a half to two minutes. **Do not heat.**

Legal category POM.

Package quantities Vials containing 2.5 g. Boxes of 10 vials.

Further information Where desirable, the discretionary use of a suitable local anaesthetic may be used. Noxyflex (ie with amethocaine hydrochloride) may therefore be more appropriate for urological use, or when a degree of pain might be expected.

Product licence number 0184/5012

NOXYFLEX*

Presentation A white crystalline powder containing 2.5 g Noxythiolin and 10 mg Amethocaine Hydrochloride BP.

Uses Noxythiolin has a wide spectrum of antifungal and antibacterial activity. It is intended for the prevention and eradication of infection from the body surface and

specified accessible cavities, particularly for urological use, or when a degree of pain might be expected.

Dosage and administration The solution is most commonly used at concentrations of 1, 2.5 and occasionally 5%. For prophylactic use a 1% solution is frequently employed; for therapeutic use, a 2.5% solution is normally administered. Ensure contact of the solution on the body surface or in specified cavities for at least 30 minutes. The period of treatment should not normally extend beyond 72 hours, or five days where otherwise stated above.

Gynaecology: Intermittent catheterisation: Use 100 ml of 1% solution at each catheterisation as prophylaxis; for treatment, use a 2.5% solution.

Indwelling catheters: Use 100 ml of 1% solution twice daily as prophylaxis; for treatment, use a 2.5% solution.

Urology and surgery: Catheterisation: 100 ml of 1% solution once or twice daily as prophylaxis. 100 ml of 2.5% solution once or twice daily as a treatment.

Infected wounds and fistulae: Irrigate with 1% Solution twice daily for five days.

Burns: 1% Solution as a wet dressing, twice daily.

Abscess cavities: 2.5% Solution via polythene tube, twice daily for five days.

Radiotherapy (Ca Bladder): 50 ml of 2.5% Solution administered via catheter during planning.

Contra-indications, warnings, etc Noxyflex can be used concurrently with the administration of systemic drugs. The use of Noxyflex in conjunction with other pharmaceutical agents for combined irrigation/instillation therapy is not recommended and solution preparation should be carried out as stated under 'Pharmaceutical preparation'. The normal daily usage of Noxyflex in adults should not exceed 10 g for either accumulative (ie. repeated) instillation regimens or continuous irrigation regimens. Solutions are not intended for intravenous use.

Pharmaceutical precautions *Storage of powder:* The powder vials should be kept in a cool place.

Storage of Solution: Solution should be kept at 2–10°C and used within 7 days. Containers of prepared solution are intended for single use only.

Solution Preparation: The powder should be dissolved completely in a sufficient quantity of Water for Injections BP or Sodium Chloride Intravenous Infusion BP (0.9 per cent w/v) by an aseptic technique. Slight difficulty may be experienced in preparing solutions.

Legal category POM.

Package quantities Vials containing 2.5 g. Boxes of 10 vials.

Further information In those situations where the inclusion of local anaesthetic is undesirable or unnecessary, Noxyflex 'S' should be used.

Product licence number 0184/5013.

* *Trade Mark*

ALTHESIN*

Presentation Althesin is a clear, colourless, ready-prepared solution that is isotonic with blood. Each millilitre of Althesin contains 9 mg alphaxalone (3 α -hydroxy-5 α -pregnane-11, 20-dione) and 3 mg alphadolone acetate (21-acetoxy-3 α -hydroxy-5 α -pregnane-11, 20-dione).

The latter steroid has about one-half the anaesthetic activity of the former, and is included to improve the solubility of alphaxalone. The aqueous vehicle contains 20% of a polyoxyethylated castor oil (a surfactant) and is rendered isotonic with sodium chloride.

Uses Induction of anaesthesia. Maintenance of anaesthesia. Experience is insufficient at present to advocate use of Althesin in infants under 1 year and for maintenance of anaesthesia in obstetrics.

Dosage and administration As usual, it is recommended that patients should fast before receiving Althesin.

Induction of anaesthesia: For adults, undiluted Althesin should be administered intravenously allowing at least 20 seconds per millilitre of injection. The induction dose for adults of average size is between 1.5 and 3.5 ml requiring between 30 and 70 seconds to administer. Alternatively, the induction dose may be calculated on the basis of 0.025–0.05 ml (25–50 microlitres) per kg body weight.

Children tend to require proportionately higher doses than adults within the 0.05 to 0.075 ml/kg body weight range, and younger children may need 0.075 ml/kg. The approximate duration of anaesthesia after a dose of 0.05 ml/kg is seven minutes, and 11 minutes after 0.075 ml/kg. Althesin has negligible analgesic activity. Althesin is pharmacologically compatible with the muscle relaxants, premedicant drugs, and inhalation anaesthetics in current clinical use.

Maintenance of anaesthesia: For short procedures, incremental doses of undiluted Althesin may be given. In dilatation and curettage, for example, after induction of anaesthesia by slow injection of Althesin, additional doses of 0.5–1 ml, according to the weight and response of the patient, may be given for swabbing the perineum and manipulating the cervix.

For longer procedures, intravenous infusion of diluted Althesin is usually preferred. The dosage normally totals 10–20 ml Althesin per hour. A convenient strength for infusion is 10% by volume of Althesin in Sodium Chloride Injection or 5% Dextrose Injection.

Althesin does not provide sufficient analgesia for operations involving painful stimuli, and this should be provided by the premedication, intravenous analgesics such as pethidine in small increments, or by local or regional anaesthetic techniques. Analgesia may also be provided by nitrous oxide.

Muscle relaxants may be used, and the patient ventilated with oxygen-enriched air. In paralysed

patients the level of anaesthesia is assessed by observing autonomic activity.

As with volatile anaesthetics, some prolongation of recovery time may occur with maintenance techniques, particularly when several doses of analgesics have been given. Oxygen is often added to the inspired air when using infusions or repeated doses of Althesin, particularly when opiate analgesics have been given and the patient is breathing spontaneously.

Contra-indications, warnings, etc

Contra-indications: Previous adverse reactions to Althesin.

Its use in patients with liver disease may be considered, although evidence at present is insufficient to advocate use in patients with complete liver failure.

Precautions: Like other anaesthetics, Althesin should be used only in the presence of an experienced anaesthetist, and resuscitative equipment should be immediately available.

The risk of severe reactions (see below) may be higher in patients with a personal or family history of atopy or those who have recently had a prior exposure to Althesin or to another Cremophor* (BASF-Germany) containing agent.

Since Althesin produces relaxation of the jaw muscles, the jaw requires support to prevent obstruction of the airway. Concurrent use of other depressants of the central nervous system may retard recovery of full consciousness, and recovery from anaesthesia should, as always, be assessed carefully before allowing out-patients to go home or resume normal activities.

Animal experiments show no evidence of teratogenicity, but Althesin should be used with caution in pregnancy.

Side-effects: Minor side-effects may include a transient flush and muscle twitching, the latter occurring more often in patients given hyoscine alone as premedication. There is a possibility of generalised convulsions, and of cardiac arrhythmias in patients concomitantly treated with muscle relaxants. Short periods of coughing, hiccoughing, salivation, laryngospasm or shivering may occur, particularly in association with light anaesthesia or rapid injection. Mild euphoria or depression during recovery from Althesin anaesthesia sometimes occurs. Post-operative nausea and vomiting are infrequent.

There have been occasional reports of more severe reactions. Bronchospasm and/or a marked drop in blood pressure may be accompanied by a generalised flushing of deep red or purplish colour, and followed by some oedema of lips and eyelids. Such reactions may require treatment with pure oxygen, intravenous corticosteroids and plasma expanders.

Overdosage: If serious respiratory depression occurs, respiration should be supported mechanically. The margin of safety is wide, and 0.2 ml/kg, or eight times the minimum recommended sleep dose, has been given as a single dose without serious effects.

Pharmaceutical precautions Do not refrigerate, as this may precipitate the steroids, which are difficult to re-solubilise. Protect from light. Do not shake, as this may cause frothing.

Legal category POM.

Package quantities Ceramically printed 5 or 10 ml ampoules in boxes of 10 ampoules.

Further information Althesin does not appear to be retained in the tissues, and is rapidly inactivated by the liver. As a result, there is considerably less cumulation than with the barbiturates. Recovery from a single dose is therefore rapid, and in maintenance anaesthesia the dosage requirements remain relatively constant, and recovery is progressive. Because of the great capacity of the liver to metabolise the constituents of Althesin, this agent may be considered for induction and maintenance of anaesthesia in patients with chronic liver disease.

Althesin is practically non-irritant, so that leakage outside the vein is unlikely to damage surrounding tissue.

Maintenance anaesthesia with Althesin (together with analgesics) can enable volatile agents to be avoided, and the atmosphere kept free of contamination by anaesthetics.

Product licence number 0004/0189.

BETNELAN* TABLETS

Presentation Small white tablets engraved 'Betnelan Glaxo' on one side and scored on the reverse. Each tablet contains 0.5 mg betamethasone.

The product complies with the specification for Betamethasone Tablets BP.

Uses Betamethasone is a glucocorticosteroid which is about eight to ten times as active as prednisolone on a weight-for-weight basis.

A wide variety of diseases may sometimes require corticosteroid therapy. Some of the principal indications are: asthma, severe allergic disturbances, leukaemia, rheumatoid arthritis, collagen diseases and various inflammatory skin diseases. Other indications are the ephrotic syndrome, ulcerative colitis, regional ileitis (Crohn's disease), pemphigus, sarcoidosis (especially with hypercalcaemia), rheumatic carditis, ankylosing spondylitis and various blood dyscrasias, including selected cases of haemolytic anaemia, agranulocytosis and thrombocytopenic purpura.

Dosage and administration The lowest dosage that will produce an acceptable result should be used; when it is possible to reduce the dosage, this must be accomplished by stages. During prolonged therapy, dosage may need to be increased temporarily during periods of stress or in exacerbations of illness.

Adults: The dose used will depend upon the disease, its severity and the clinical response obtained. The following regimens are for guidance only. Divided dosage is usually employed.

Short-term treatment: 2–3 mg daily for the first few days, subsequently reducing the daily dosage by 0.25 or 0.5 mg every two to five days, depending upon the response.

Rheumatoid arthritis: 0.5–2 mg daily. For maintenance therapy the lowest effective dosage is used.

Most other conditions: 1.5–5.0 mg daily for one to three weeks, then reducing to the minimum effective dosage.

Larger doses may be needed for collagen diseases and ulcerative colitis.
